1 **Abstract**

2 Analyses of a sediment core from Highstead Swamp in southwestern Connecticut, USA
3 reveal late-glacial and early-Holocene ecological and hydrological changes. Late-glacial pollen
4 assemblages are dominated by *Picea* and *Pinus* subg. *Pinus*, and the onset of the Younger Dryas
5 (YD) cold interval is evidenced by higher abundance of *Abies* and *Alnus viridis* subsp. *crispa*.
6 As climate warmed at the end of the YD, *Picea* and *Abies* declined and *Pinus strobus* became the
7 dominant upland tree species. A shift from lacustrine sediment to organic peat at the YD-
8 Holocene boundary suggests that the lake that existed in the basin during the late-glacial interval
9 developed into a swamp in response to reduced effective moisture. A change in wetland
10 vegetation from *Myrica gale* to *Alnus incana* subsp. *rugosa* and *Sphagnum* is consistent with this
11 interpretation of environmental changes at the beginning of the Holocene.

12
13 **Introduction**

14 Environmental and ecological changes associated with the Younger Dryas (YD) climatic
15 oscillation (12,900-11,600 calibrated ¹⁴C years before present; cal yr BP) have been studied at
16 many sites in eastern North America using a variety of approaches (e.g., Peteet et al., 1990;
17 Levesque et al., 1993; Mayle et al., 1993; Cwynar and Levesque, 1995; Shemesh and Peteet,
18 1998; Yu and Eicher, 1998; Lavoie and Richard, 2000; Newby et al., 2000; Cwynar and Spear,
19 2001; Huang et al., 2002; Shuman et al., 2001, 2002; Hou et al., 2007; Lindbladh et al., 2007;
20 Yu, 2007). Pollen records typically feature an increase in cold-tolerant taxa at the beginning of
21 the YD and a shift to taxa indicative of warmer conditions at the YD-Holocene boundary (e.g.,
22 Shuman et al., 2002). Quantitative reconstructions of temperature for this interval yield
23 generally consistent results, indicating ~5°C shifts at the beginning and end of the YD (Shemesh

1 and Peteet, 1998; Yu et al., 1998; Cwynar and Spear, 2001; Yu, 2007). Late-glacial changes in
2 moisture balance, on the other hand, have received less study. Lake-level reconstructions from
3 southern Québec (Lavoie and Richard, 2000) and southeastern Massachusetts (Newby et al.,
4 2000; Shuman et al., 2001) indicate relatively wet conditions during the YD and drier climate at
5 the beginning of the Holocene, but other records of moisture-balance shifts associated with the
6 YD have not been developed. In this paper we report on a late-glacial sedimentary record from a
7 swamp in southwestern Connecticut, USA. Analyses of pollen and organic content provide
8 additional insights into changes in moisture balance at the end of the YD.

9

10 **Study Area**

11 Highstead Swamp (41° 19.5' N, 73° 23.75' W) is located at Highstead, a 150-acre
12 woodland preserve in Redding, Connecticut. This area of southwestern Connecticut falls within
13 the Northeastern Coastal Zone, an ecoregion that extends across southern New England (Griffith
14 et al., 1994).

15

16 The swamp is part of a 4-ha seasonally flooded basin; it has an intermittent outlet stream
17 that drains into a 1-ha artificial pond before continuing to the southeast. Soils range from muck
18 to poorly drained and stony (Wolf, 1981). The swamp is bounded to the west by a rugged
19 northeast-to-southwest trending ridge of Ordovician-age schist and granitic gneiss; to the east is
20 a smooth, northwest trending drumlin composed of Wisconsinan glacial till overlying Illinoian
21 till (Rodgers, 1985; Stone et al., 2005). The vegetation of the swamp features *Acer rubrum* and
22 *Betula alleghaniensis* in the overstory, *Clethra alnifolia*, *Lindera benzoin*, and *Ilex verticillata* in
23 the understory, and a ground layer of *Symplocarpus foetidus*, *Osmunda cinnamomea*, and *Carex*

1 species. Dry, upland forest to the west consists of 70-90 year old *Quercus rubra*, *Q. coccinea*,
2 and *Q. prinus*, with dense *Kalmia latifolia* in the understory. To the east, moist *Acer rubrum*,
3 *Fraxinus americana*, and *Liriodendron tulipifera* forest (45-85 years old) occurs on fine-grained
4 soils. The *Quercus* forest was continuously forested during the European settlement period but
5 was cut heavily for wood products, while the *Acer-Fraxinus* forest was open pasture during the
6 settlement period and reverted back to woodland only in the twentieth century.

7

8 **Methods**

9 We collected a sediment core from Highstead Swamp in June of 2006. We accessed the
10 center of the swamp using an established boardwalk and collected a 256-cm-long core using a
11 modified Livingston piston sediment sampler. Core segments were extruded horizontally in the
12 field, wrapped in plastic and aluminum foil, and subsequently refrigerated.

13

14 The analyses presented here were performed on the interval of the core from 256 to 94
15 cm; the upper interval of the core appeared to be disturbed and therefore was not analyzed.
16 Sediment samples of 1 cm³ were prepared for pollen analysis following standard procedures
17 (Faegri and Iversen, 1989), and tablets containing *Lycopodium clavatum* spores were added
18 during processing to allow calculation of pollen and spore concentrations (Stockmarr, 1971).
19 Pollen residues were mounted in silicone oil and analyzed at 400x magnification. At least 500
20 pollen grains and spores of upland plant taxa were counted for each sample, and pollen
21 percentages were calculated relative to that sum. *Myrica*-type pollen, which is very abundant in
22 samples from 134 and 138 cm, was not included in the sum used to calculate percentage values.

1 Sediment organic content was estimated for 1-cm³ samples at selected depths by percent weight
2 loss-on-ignition (LOI) at 550 °C.

3
4 Chronological control is provided by accelerator mass spectrometry ¹⁴C analysis of four
5 woody plant macrofossils sieved from the sediment (Table 1). Dates were converted to
6 calibrated ¹⁴C years before present (cal yr BP) with CALIB 5.0 (Stuiver and Reimer, 1993). The
7 date of the uppermost sample (~11,900 cal yr BP; 109 cm) is inconsistent with the age-depth
8 relationship of the other dates and data from other sites, and is therefore rejected.

10 **Results**

11 The lower section of the core (256-210 cm; ~13,300-13,000 cal yr BP) is lacustrine
12 sediment featuring pollen assemblages dominated by *Picea* (~30%) and *Pinus* subgenus *Pinus*
13 (~30%), with minor abundances of *Ostrya-Carpinus*, *Fraxinus*, *Quercus*, *Betula*, Poaceae,
14 Cyperaceae, and pteridophytes (Fig. 2). Organic content increases from ~50 to 60% during this
15 interval (Fig. 3). Various changes occur after ~13,000 cal yr BP (220-200 cm), including
16 increased abundance of *Abies*, *Alnus*, *Nuphar*, and *Myrica*-type and decreasing percentages for
17 *Ostrya-Carpinus*, *Fraxinus*, *Quercus*, Poaceae, and pteridophytes (Fig. 2-3). Organic content
18 declines abruptly between ~220 and 200 cm, then increases from ~50 to 70% between 200 and
19 140 cm. The upper section of the core (140-90 cm; <11,500 cal yr BP) changes abruptly to peaty
20 sediment, with organic content increasing from ~70 to 90%. This interval has a dramatic decline
21 in *Picea* pollen percentages (~30 to <5%) and a corresponding rise in *Pinus* subgenus *Strobus*
22 abundance (~5 to 60%). *Abies* abundance declines above 140 cm, whereas *Tsuga* pollen reaches
23 ~2-3% and *Alnus* pollen peaks at ~40%. *Myrica*-type pollen becomes very abundant in samples

1 at the beginning of this transition (Fig. 3), just before the peak in *Alnus* pollen percentages, while
2 *Sphagnum* spores reach a peak coincident with the highest *Alnus* values.

3

4 **Discussion**

5 The changes observed in the Highstead Swamp record at ~13,000 cal yr BP, including
6 declining percentages of *Ostrya-Carpinus* pollen and higher abundances of *Abies* and *Alnus*
7 (presumably *A. viridis* subsp. *crispa*), are consistent with pollen data from sites in southern New
8 England (e.g., Davis, 1969; Suter, 1985; Lindbladh et al., 2007) and elsewhere in eastern North
9 America (e.g., Mayle et al., 1993; Peteet et al., 1993). The ~5°C drop in temperatures at the
10 beginning of the YD (Shemesh and Peteet, 1998; Yu et al., 1998; Cwynar and Spear, 2001; Yu,
11 2007) appears to have shifted vegetation assemblages across the region towards cold-tolerant
12 taxa (Shuman et al. 2002), although some ecological changes may have been underway in
13 advance of the onset of YD cooling (Lindbladh et al., 2007).

14

15 The end of the YD cold interval in the Highstead Swamp record is also marked by
16 changes in vegetation seen at other sites. *Picea* pollen percentages decline abruptly at ~11,500
17 cal yr BP, and boreal taxa such as *Abies* are replaced by temperate taxa including *Pinus strobus*,
18 *Tsuga canadensis*, and *Quercus* (e.g., Mayle et al., 2003; Shuman et al. 2002; Lindbladh et al.,
19 2007). A comparison of pollen and paleoclimatic data by Williams et al. (2002) indicates that
20 vegetation responded quickly to rising temperatures at the beginning of the Holocene. The peak
21 in *Alnus* pollen percentages at the YD-Holocene boundary in the Highstead Swamp record,
22 however, is not a feature that is normally observed in other pollen records from eastern North
23 America (but see Newby et al., 2002). In fact, the decline of *Alnus* is typically seen as a

1 distinguishing marker of the end of the YD (Mayle et al., 1993). We interpret the increase in
2 *Alnus* abundance, as well as the rise in *Myrica*-type pollen occurring just prior to the *Alnus* peak,
3 as evidence for changes in the composition of the local vegetation in response to a shift in
4 moisture availability and hydrological conditions at the beginning of the Holocene.

5
6 Several lines of evidence from the Highstead Swamp record indicate a sequence of
7 hydrological and ecological changes during the transition from the YD to the Holocene. The
8 decline in the abundance of *Nuphar*, an aquatic plant, and shift from lacustrine sediment to peat
9 suggest that the lake that occupied the basin during the late-glacial interval became a swamp
10 after ~11,500 cal yr BP. A similar transition in the sediments of Makepeace Cedar Swamp,
11 located in southeastern Massachusetts, was also interpreted as a shift from lake to swamp at the
12 beginning of the Holocene (Newby et al., 2000). The changes in wetland vegetation at
13 Highstead Swamp are consistent with this interpretation. The wet substrate of the swamp was
14 initially dominated by *Myrica gale*, as evidenced by the high abundance of *Myrica*-type pollen,
15 and subsequent development of the swamp likely allowed *Alnus* and *Sphagnum* to become
16 prevalent. We suspect that the *Alnus* pollen represents the presence of *Alnus incana* subsp.
17 *rugosa*, which can occur with *Sphagnum* in bogs and swamps in eastern North America (e.g.,
18 Cronan and DesMeules, 1985).

19
20 Taken together, the changes observed in the sedimentary record from Highstead Swamp
21 are consistent with lake-level studies from eastern North America (Lavoie and Richard, 2000;
22 Newby et al., 2000; Shuman et al., 2001), which suggest that water levels declined ~11,500 cal
23 yr BP in response to declining effective moisture. Those dry conditions prevailed in New

1 England until ~8000 cal yr BP, when the deterioration of the Laurentide Ice Sheet brought wetter
2 climate to the region (e.g., Shuman et al., 2006).

3

4 **Acknowledgements**

5 We thank Highstead (www.highstead.net) for their support of this research. Bryan
6 Shuman, Jason Briner, and two anonymous reviewers provided valuable suggestions. Alex
7 Ireland helped in the field and Brian Hall assisted with figures.
