(Received 10 December 2006; published 26 January 2007)

The time-dependent Gross-Pitaevskii equation describes the dynamics of initially trapped Bose-Einstein condensates. We present a rigorous proof of this fact starting from a many-body bosonic Schrödinger equation with a short-scale repulsive interaction in the dilute limit. Our proof shows the persistence of an explicit short-scale correlation structure in the condensate.

Recent experiments on trapped Bose gases in the condensate phase [1,2] have revived interest in the rigorous justification of the Gross-Pitaevskii (GP) theory from interacting many-body Hamiltonians. In these experiments, the gas is initially trapped by a strong magnetic field and cooled down at very low temperatures, so that almost all particles condensate in the same collective mode described by a one-particle wave function  $\varphi(\mathbf{r})$ ,  $\mathbf{r} \in \mathbb{R}^3$ . Then the traps are instantaneously removed, and the evolution of the condensate is observed. To describe this evolution, the GP theory [3–5] postulates that many-body effects can be compressed into a nonlinear on-site interaction. In units where  $\hbar = 1$  and the mass of the bosons  $m = 1/2$ , the condensate wave function at time  $t$ ,  $\varphi_t = \varphi_t(\mathbf{r})$ , satisfies the GP equation

$$i\partial_t \varphi_t = -\Delta_{\mathbf{r}} \varphi_t + \sigma |\varphi_t|^2 \varphi_t, \quad (1)$$

with the normalization  $\int |\varphi_t(\mathbf{r})|^2 d^3\mathbf{r} = 1$ . The coupling constant is  $\sigma = 8\pi Na$ , where  $N$  is the number of particles and  $a$  is the scattering length of the interaction potential.

A single orbital theory might indicate that the full  $N$ -body wave function essentially factorizes. This, however, is usually not the case: Very short-scale interactions may introduce strong pair correlations that substantially influence the energy of the system and the dynamics even on larger scales. In particular, the emergence of the scattering length in  $\sigma$  is a correlation effect, and it is remarkable that this correlation can be consistently modeled by the same coupling constant along the whole evolution.

The GP equation thus implicitly postulates a persistent two-scale structure of the state. On short scales, the state exhibits a time-independent pair correlation, while on large scales it is given by the product of  $N$  copies of a time-dependent orbital. It is a fundamental problem in many-body theory to show that the GP postulation of a two-scale structure is a rigorous consequence of the first principle many-body Schrödinger equation. While many theoretical works addressed this question for low energy states, there is no rigorous result from a dynamical point of view.

In this Letter, we shall show not only that the two-scale structure is *preserved* but that it even *emerges* dynamically for a class of initial data.

On the mathematically rigorous level, the GP theory has been verified only for the ground state of the trapped Bose gas. Lieb, Seiringer, and Yngvason [6] considered a model where the scattering length  $a$  of the interaction varies with  $N$ , so that  $Na$  remains constant. For repulsive interactions, they proved that the ground state energy per particle in the GP limit ( $N \rightarrow \infty$ ,  $a_0 = Na = \text{fixed}$ ) is given by a variational principle  $\min\{\mathcal{E}_{\text{GP}}(\varphi): \|\varphi\| = \|\varphi\|_{L^2(\mathbb{R}^3)} = 1\}$ , where

$$\mathcal{E}_{\text{GP}}(\varphi) = \int_{\mathbb{R}^3} (|\nabla\varphi|^2 + V_{\text{ext}}|\varphi|^2 + 4\pi a_0|\varphi|^4) \quad (2)$$

is the GP energy functional. This result was extended to rotating Bose systems that model superfluidity in Ref. [7].

In Ref. [8], Lieb and Seiringer have also rigorously established that the ground state of the trapped Bose gas exhibits a complete Bose-Einstein condensation by showing that the one-particle density matrix of the ground state converges to the one-dimensional projection  $|\varphi_{\text{GP}}\rangle\langle\varphi_{\text{GP}}|$ , where  $\varphi_{\text{GP}}$  is the minimizer of the functional  $\mathcal{E}_{\text{GP}}$ .

The ground state has been known to have a nontrivial pair correlation. Mathematically, this was first exploited for the homogeneous dilute Bose gas by Dyson [9] to verify the upper bound on the ground state energy obtained from Bogoliubov theory. The proof of the lower bound, achieved by Lieb and Yngvason 40 years later [10], demonstrates that low energy states necessarily contain a characteristic short-scale pair correlation. In the GP limit, as shown in Ref. [6], the trapping potential introduces a second length scale, but it leaves the short-scale structure intact.

The works mentioned above justify the two-scale hypothesis of the GP theory based on the energy minimizing principle. In this Letter, we outline a mathematical proof (see Ref. [11] for details) of the fact that the GP theory also describes the dynamics of trapped Bose-Einstein condensates. Assuming that at time  $t = 0$  we have a condensate,

we show, under some conditions on the interaction potential and on the initial state, that the system still exhibits complete condensation at times  $t \neq 0$  and that the condensate wave function evolves according to the GP equation (1). Our results cover two types of initial data: type I states with the physical two-scale structure as in Refs. [6,8] and type II states with no short-scale structure. For type I initial data, the main difficulty is to demonstrate the persistence of the two-scale structure even for states that are far from the ground state. Energy conservation alone does not prevent the destruction of the short-scale structure. The key observation is that higher moments of the energy are also conserved, and they impose stringent restrictions on the state. In theorem 2 below, we show that a finite second moment of the energy per particle forces a pair correlation described by the zero energy scattering function of the interaction potential. For type II initial data, our results imply that the short-scale structure emerges dynamically. See the discussion after theorem 1.

The Hamiltonian for  $N$  bosons in  $\mathbb{R}^3$  is given by

$$\tilde{H}_N = \sum_{j=1}^N [-\Delta_{\mathbf{r}_j} + V_{\text{ext}}(\mathbf{r}_j)] + \sum_{i<j}^N V_N(\mathbf{r}_i - \mathbf{r}_j). \quad (3)$$

The trap potential  $V_{\text{ext}}(\mathbf{r})$  is a positive function, with  $V_{\text{ext}}(\mathbf{r}) \rightarrow \infty$  as  $|\mathbf{r}| \rightarrow \infty$ . The interaction potential is scaled as  $V_N(\mathbf{r}) = N^2 V(N\mathbf{r})$ , where  $V$  is a positive, spherically symmetric, compactly supported, smooth potential with scattering length  $a_0$ . By scaling, the scattering length of  $V_N$  is  $a_0/N$ . We assume that the strength of the interaction, measured by  $\alpha = \int V(\mathbf{r})|\mathbf{r}|^{-1} d\mathbf{r} + \sup_{\mathbf{r} \in \mathbb{R}^3} \mathbf{r}^2 V(\mathbf{r})$ , is sufficiently small.

Let  $\psi_N$  be the ground state of (3) and let  $\gamma_N^{(k)}$  be its  $k$ -particle marginal density ( $1 \leq k \leq N$ ) with a consistent normalization  $\text{Tr} \gamma_N^{(k)} = 1$ . It was proven in Ref. [8] that

$$\gamma_N^{(k)} \rightarrow |\varphi_{\text{GP}}\rangle\langle\varphi_{\text{GP}}|^{\otimes k}, \quad N \rightarrow \infty, \quad (4)$$

for any fixed  $k$ . In particular, (4) for  $k = 1$  means that  $\psi_N$  exhibits complete condensation.

After instantaneously removing the trap, the evolution of the system is generated by the Hamiltonian

$$H_N = \sum_{j=1}^N -\Delta_{\mathbf{r}_j} + \sum_{i<j}^N V_N(\mathbf{r}_i - \mathbf{r}_j). \quad (5)$$

*Theorem 1.*—Let  $\psi_{N,t}$  be the solution to the Schrödinger equation  $i\partial_t \psi_{N,t} = H_N \psi_{N,t}$ , with the initial condition  $\psi_{N,0} = \psi_N$ , and let  $\gamma_{N,t}^{(1)}$  be its one-particle marginal density. Then, for any fixed time  $t \in \mathbb{R}$ ,  $\psi_{N,t}$  exhibits complete Bose-Einstein condensation; that is,

$$\text{Tr} |\gamma_{N,t}^{(1)} - |\varphi_t\rangle\langle\varphi_t|| \rightarrow 0 \quad \text{as } N \rightarrow \infty, \quad (6)$$

where  $\varphi_t$  solves the Gross-Pitaevskii equation (1) with  $\sigma = 8\pi a_0$  and with initial data  $\varphi_{t=0} = \varphi_{\text{GP}}$ .

Our proof, in fact, allows for more general initial data. Let  $H^1(\mathbb{R}^3) := \{\varphi(\mathbf{r}): \int |\varphi|^2 + |\nabla\varphi|^2 < \infty\}$ . The technical condition we need to conclude (6) is that the initial state

$\psi_{N,0}$  asymptotically factorizes, in the sense that there exists  $\varphi \in H^1(\mathbb{R}^3)$  and for every  $k \geq 1$  there exists a family  $\{\xi_N^{(N-k)}\}_{N \geq k}$ , with  $\xi_N^{(N-k)} \in L^2(\mathbb{R}^{3(N-k)})$  and  $\|\varphi\| = \|\xi_N^{(N-k)}\| = 1$  such that

$$\lim_{N \rightarrow \infty} \|\psi_{N,0} - \varphi^{\otimes k} \otimes \xi_N^{(N-k)}\| = 0. \quad (7)$$

The function  $\varphi$  is then the initial data for (1). As we prove in Ref. [11], the ground state  $\psi_N$  of the Hamiltonian (3) satisfies (7). This shows that the pair correlations of  $\psi_N$ , which affect the dynamics in a nontrivial way, are not in conflict with the asymptotic factorization as long as the convergence in (7) is in a weaker topology than the energy norm.

The local correlation structure of  $\psi_N$  lives on a length scale  $1/N$ , and its effect, measured in the  $L^2$  sense in (7), is negligible. However, the energy of  $\psi_N$  does not converge to the energy of the factorized state, and, similarly, the convergence in (4) does not hold in the  $H^1$  space or in the energy sense.

Typical type II initial data are given by a product wave function  $\psi_{N,0} = \varphi^{\otimes N}$ , with  $\varphi \in H^1(\mathbb{R}^3)$ . For  $\psi_{N,0}$ , the condition (7) holds trivially. Our result thus shows that a product initial state also evolves according to the GP equation [5] (with initial data  $\varphi_{t=0} = \varphi$ ) despite the fact that its total energy is larger than  $\mathcal{E}_{\text{GP}}(\varphi)$ . In fact, it is easy to see that the energy per particle in the factorized state  $\langle \varphi^{\otimes N}, (\tilde{H}_N/N) \varphi^{\otimes N} \rangle$  is asymptotically given by a functional similar to (2) but with  $8\pi a_0$  replaced with its Born approximation  $b_0 = \int V(\mathbf{r}) d^3\mathbf{r}$ . Note that  $b_0 > 8\pi a_0$ . This indicates that the excess energy originating from the emergence of the scattering length is dispersed into modes that do not influence the evolution of the condensate. Hence, for product initial data, the scattering length emerges dynamically, and the energy functional of the single particle orbitals does not predict the evolution equation.

*Outline of the proof.*—For  $k = 1, \dots, N$ , let  $\gamma_{N,t}^{(k)}$  denote the  $k$ -particle marginal density of  $\psi_{N,t}$  with a consistent normalization  $\text{Tr} \gamma_{N,t}^{(k)} = 1$ . The time evolution is governed by a hierarchy of  $N$  coupled equations, commonly known as the Bogoliubov-Born-Green-Kirkwood-Yvon hierarchy

$$i\partial_t \gamma_{N,t}^{(k)} = \sum_{j=1}^k [-\Delta_{\mathbf{r}_j}, \gamma_{N,t}^{(k)}] + \sum_{i<j}^k [V_N(\mathbf{r}_i - \mathbf{r}_j), \gamma_{N,t}^{(k)}] \\ + (N-k) \sum_{j=1}^k \text{Tr}_{k+1} [V_N(\mathbf{r}_j - \mathbf{r}_{k+1}), \gamma_{N,t}^{(k+1)}], \quad (8)$$

where  $\text{Tr}_{k+1}$  denotes the partial trace over  $\mathbf{r}_{k+1}$ . By the Banach-Alaouglu theorem,  $\gamma_{N,t}^{(k)}$  has at least one weak\* limit point  $\gamma_{\infty,t}^{(k)}$  in the space of trace class operators. Since formally  $NV_N(\mathbf{r}) = N^3 V(N\mathbf{r}) \rightarrow b_0 \delta(\mathbf{r})$ , one may naively expect from (8) the time evolution of  $\gamma_{\infty,t}^{(k)}$  to be described by the infinite hierarchy

$$i\partial_t \gamma_{\infty,t}^{(k)} = \sum_{j=1}^k [-\Delta_{\mathbf{r}_j}, \gamma_{\infty,t}^{(k)}] + \sigma B^{(k)} \gamma_{\infty,t}^{(k+1)}, \quad (9)$$

with the collision operator

$$B^{(k)}\gamma^{(k+1)} = \sum_{j=1}^k \text{Tr}_{k+1}[\delta(\mathbf{r}_j - \mathbf{r}_{k+1}), \gamma^{(k+1)}],$$

and with  $\sigma = b_0$ . However, the coupling constant in the correct equations for  $\gamma_{\infty,t}^{(k)}$  is  $\sigma = 8\pi a_0$ . The reason is that  $\gamma_{N,t}^{(k+1)}$  develops a short-scale structure which lives on the same length scale  $\ell \simeq 1/N$  as the potential  $V_N$ . Since  $\gamma_{N,t}^{(k+1)}$  is not constant on this length scale, one cannot apply the formal limit  $NV_N \rightarrow b_0\delta$  in (8).

In the following theorem 2, we show that, for  $\mathbf{r}_j$  close to  $\mathbf{r}_{k+1}$ , the short-scale structure of  $\gamma_{N,t}^{(k+1)}$  is described by the function  $f_N(\mathbf{r}_j - \mathbf{r}_{k+1})$ , where  $f_N$  is the solution to the zero energy scattering equation  $[-\Delta + \frac{1}{2}V_N(\mathbf{r})]f_N(\mathbf{r}) = 0$ , with boundary condition  $f_N(\mathbf{r}) \rightarrow 1$  as  $|\mathbf{r}| \rightarrow \infty$ . By scaling,  $f_N(\mathbf{r}) = f(N\mathbf{r})$ , where  $f$  is a solution of  $(-\Delta + \frac{1}{2}V)f = 0$  with the same boundary condition. Therefore, the correct value of  $\sigma$  in (9) is given by

$$\sigma = \int d^3\mathbf{r} NV_N(\mathbf{r})f_N(\mathbf{r}) = \int d^3\mathbf{r} V(\mathbf{r})f(\mathbf{r}) = 8\pi a_0.$$

Note that the short-scale structure disappears from  $\gamma_{\infty,t}^{(k)}$  after taking the weak limit, but it still affects the limiting macroscopic dynamics.

The infinite hierarchy (9) has a factorized solution: The family  $\gamma_{\infty,t}^{(k)} = |\varphi_t\rangle\langle\varphi_t|^{\otimes k}$ ,  $k \geq 1$ , is a solution to (9) with  $\sigma = 8\pi a_0$  if and only if  $\varphi_t$  is a solution to the GP equation (1). Therefore, to identify the limiting density, it suffices to show that (i) any limit point  $\{\gamma_{\infty,t}^{(k)}\}_{k \geq 1}$  of the family of densities  $\{\gamma_{N,t}^{(k)}\}_{k=1}^N$  is a solution of the infinite hierarchy (9) with  $\sigma = 8\pi a_0$ , and (ii) the solution to the infinite hierarchy is unique. The proofs of (i) and (ii) rely on estimates on the energy distribution of the initial wave function and on the factorization property (7).

(i) *Convergence to the infinite hierarchy.*—The following key theorem identifies the short-scale structure assuming a bound on the second moment of the energy. This is the main ingredient in the proof of (9).

*Theorem 2.*—Suppose  $\alpha$  is small enough. Then there exists a constant  $C > 0$  such that, for  $1 \leq i < j \leq N$ ,

$$\langle \psi, H_N^2 \psi \rangle \geq CN^2 \int d\mathbf{R} \left| \nabla_{\mathbf{r}_i} \nabla_{\mathbf{r}_j} \frac{\psi(\mathbf{R})}{f_N(\mathbf{r}_i - \mathbf{r}_j)} \right|^2 \quad (10)$$

holds for any  $\psi \in L^2(\mathbb{R}^{3N}, d\mathbf{R})$  that is symmetric with respect to permutations. Here  $\mathbf{R} = (\mathbf{r}_1, \dots, \mathbf{r}_N) \in \mathbb{R}^{3N}$ .

From this theorem, we obtain the *a priori* bound

$$\int d\mathbf{R} \left| \nabla_{\mathbf{r}_i} \nabla_{\mathbf{r}_j} \frac{\psi_{N,t}(\mathbf{R})}{f_N(\mathbf{r}_i - \mathbf{r}_j)} \right|^2 \leq C, \quad \forall i \neq j, \quad (11)$$

uniformly in  $N$  and  $t$  provided the initial wave function  $\psi_{N,0}$  at time  $t = 0$  satisfies  $\langle \psi_{N,0}, H_N^2 \psi_{N,0} \rangle \leq CN^2$ . Note that  $\int d\mathbf{r}_i d\mathbf{r}_j |\nabla_{\mathbf{r}_i} \nabla_{\mathbf{r}_j} f_N(\mathbf{r}_i - \mathbf{r}_j)|^2 \sim N$ ; thus, (11) identifies the short-scale structure of  $\psi_{N,t}$  with a precision  $1/N$ .

Furthermore, since the left side of (10) is a constant of motion, (11) shows that the separation between the singu-

lar short-scale structure and the regular part of  $\psi_{N,t}$  is preserved by the time evolution.

*Outline of the proof of theorem 2.*—We define  $h_m = -\Delta_{\mathbf{r}_m} + \frac{1}{2}\sum_{n \neq m} V_N(\mathbf{r}_n - \mathbf{r}_m)$ , for  $m = 1, \dots, N$ . Then  $H_N = \sum_{m=1}^N h_m$ , and, using the permutation symmetry of  $\psi$  and  $V \geq 0$ , we obtain, for arbitrary  $i \neq j$ ,

$$\begin{aligned} \frac{\langle \psi, H_N^2 \psi \rangle}{N(N-1)} &\geq \langle \psi, h_i h_j \psi \rangle \\ &\geq \left\langle \psi, \left( -\Delta_{\mathbf{r}_i} + \frac{V_N(\mathbf{r}_i - \mathbf{r}_j)}{2} \right) \right. \\ &\quad \left. \times \left( -\Delta_{\mathbf{r}_j} + \frac{V_N(\mathbf{r}_j - \mathbf{r}_i)}{2} \right) \psi \right\rangle. \end{aligned}$$

From the definition of  $f_N(\mathbf{r})$ , we find

$$\left( -\Delta_{\mathbf{r}_i} + \frac{1}{2}V_N(\mathbf{r}_i - \mathbf{r}_j) \right) \psi = f_N(\mathbf{r}_i - \mathbf{r}_j) L_i \frac{\psi}{f_N(\mathbf{r}_i - \mathbf{r}_j)},$$

with  $L_i = -\Delta_{\mathbf{r}_i} + 2\nabla_{\mathbf{r}_i}[\log f_N(\mathbf{r}_i - \mathbf{r}_j)]\nabla_{\mathbf{r}_i}$ . Using integration by parts, and with  $\phi_{ij}(\mathbf{R}) = \psi(\mathbf{R})/f_N(\mathbf{r}_i - \mathbf{r}_j)$ ,

$$\begin{aligned} \frac{\langle \psi, H_N^2 \psi \rangle}{N(N-1)} &\geq \int d\mathbf{R} f_N^2(\mathbf{r}_i - \mathbf{r}_j) |\nabla_{\mathbf{r}_i} \nabla_{\mathbf{r}_j} \phi_{ij}(\mathbf{R})|^2 \\ &\quad + \int d\mathbf{R} (f_N^2 \nabla^2 \log f_N)(\mathbf{r}_i - \mathbf{r}_j) \\ &\quad \times \nabla_{\mathbf{r}_i} \bar{\phi}_{ij}(\mathbf{R}) \nabla_{\mathbf{r}_j} \phi_{ij}(\mathbf{R}). \end{aligned}$$

Equation (10) now follows because  $|\nabla^2 \log f_N(\mathbf{r}_i - \mathbf{r}_j)| \leq C\alpha|\mathbf{r}_i - \mathbf{r}_j|^{-2}$ , and, therefore, the second term on the right-hand side of the last equation can be controlled by the first one (for  $\alpha$  small enough) using the operator inequality  $|\mathbf{r}|^{-2} \leq -C\Delta_{\mathbf{r}}$  (Hardy inequality).

(ii) *Uniqueness of the infinite hierarchy.*—The first step is to prove *a priori* bounds in a certain Sobolev norm.

*Theorem 3.*—Let  $\gamma_{\infty,t}^{(k)}$  be any weak limit point of  $\gamma_{N,t}^{(k)}$ ; then the following estimate holds uniformly in time:

$$\|\|\|\gamma_{\infty,t}^{(k)}\|\|\|_k := \text{Tr}(1 - \Delta_{\mathbf{r}_1}) \dots (1 - \Delta_{\mathbf{r}_k}) \gamma_{\infty,t}^{(k)} \leq C^k. \quad (12)$$

*Idea of the proof.*—By conservation of  $H_N^k$  along the evolution,  $\text{Tr} H_N^k \gamma_{N,t}^{(k)} = \text{Tr} H_N^k \gamma_{N,0}^{(k)}$ . A control on  $\text{Tr} H_N^k \gamma_{N,0}^{(k)}$  can be obtained through (7). The difficulty is that the norm  $\|\|\|\cdot\|\|\|_k$  cannot be directly controlled by  $\text{Tr} H_N^k(\cdot)$  and, in fact,  $\|\|\|\gamma_{N,t}^{(k)}\|\|\|_k \rightarrow \infty$  as  $N \rightarrow \infty$  because of the singular short-scale structure. It is only after taking the weak limit  $N \rightarrow \infty$  that the short-scale structure disappears and (12) can be proven.

For illustration, consider the case  $k = 2$  discussed in theorem 2. The estimate (11) implies that  $\psi_{N,t}(\mathbf{R}) \sim f_N(\mathbf{r}_i - \mathbf{r}_j) \phi_t(\mathbf{R})$ , where  $\phi_t$  is a smooth function in the variable  $\mathbf{r}_i - \mathbf{r}_j$ . Together with the fact that  $\int d\mathbf{r}_i d\mathbf{r}_j |\nabla_{\mathbf{r}_i} \nabla_{\mathbf{r}_j} f_N(\mathbf{r}_i - \mathbf{r}_j)|^2 \sim N$ , we have that  $\int d\mathbf{R} |\nabla_{\mathbf{r}_i} \nabla_{\mathbf{r}_j} \psi_N(\mathbf{R})|^2 \rightarrow \infty$  as  $N \rightarrow \infty$ . However, since  $f_N \rightarrow 1$  weakly in the  $L^2$  sense (but not in the energy sense), a Sobolev estimate on the limit of the density matrix of  $\psi_{N,t}$  can be deduced from (11).

*Theorem 4.*—Given a family of densities  $\Gamma = \{\gamma^{(k)}\}_{k \geq 1}$  such that  $\|\|\gamma^{(k)}\|\|_k \leq C^k$ , there exists at most one solution  $\Gamma_t = \{\gamma_t^{(k)}\}_{k \geq 1}$  to (9) with  $\Gamma_{t=0} = \Gamma$  and such that  $\|\|\gamma_t^{(k)}\|\|_k \leq C^k$  holds uniformly in  $t$ .

*Outline of the proof.*—Iterating the integral form of (9), we obtain a Dyson series

$$\gamma_t^{(k)} = \mathcal{U}^{(k)}(t)\gamma^{(k)} + \sum_{m=1}^{n-1} \omega_{m,t}^{(k)} + \eta_{n,t}^{(k)}, \quad (13)$$

where  $\mathcal{U}_t^{(k)}\gamma^{(k)} = e^{it\sum_{j=1}^k \Delta_j} \gamma^{(k)} e^{-it\sum_{j=1}^k \Delta_j}$ , and

$$\begin{aligned} \omega_{m,t}^{(k)} &= (-i\sigma)^m \int_0^t ds_1 \dots \int_0^{s_{m-1}} ds_m \mathcal{U}_{t-s_1}^{(k)} B^{(k)} \dots \\ &\times B^{(k+m-1)} \mathcal{U}_{s_m}^{(k+m)} \gamma^{(k+m)}. \end{aligned} \quad (14)$$

The error term  $\eta_{n,t}^{(k)}$  has the same form as  $\omega_{n,t}^{(k)}$  with  $\mathcal{U}_{s_n}^{(k+n)}\gamma^{(k+n)}$  replaced by the full evolution  $\gamma_{s_n}^{(k+n)}$ .

To prove the convergence of the expansion (13) as  $n \rightarrow \infty$ , we expand each term into a sum of contributions associated with certain Feynman graphs. A typical graph  $\Lambda$  contributing to  $\omega_{m,t}^{(k)}$  is drawn in Fig. 1. It has  $m$  four-valent vertices and  $2k + 3m$  lines. The external lines on the left (called *roots*) correspond to the  $2k$  momenta variables of the operator kernel of  $\omega_{m,t}^{(k)}$ . The  $2(k + m)$  external lines on the right (called *leaves*) represent the kernel of  $\gamma^{(k+m)}$ . The graphical structure of  $\Lambda$  encodes the collision history given in (14). Every line  $e$  of  $\Lambda$  carries a regularized free propagator  $(\alpha_e - \mathbf{p}_e^2 \pm i/t)^{-1}$ , with a momentum variable  $\mathbf{p}_e \in \mathbb{R}^3$  and a frequency  $\alpha_e \in \mathbb{R}$ . At each vertex, there is a  $\mathbf{p}$ - and a  $\alpha$ -delta function due to momentum and energy conservation. The kernel of  $\omega_{m,t}^{(k)}$  (whose variables correspond to the  $2k$  momenta of the roots) is computed by performing  $3m$  momentum integrals and  $2k + 3m$  frequency integrals in each  $\Lambda$ .

Because of the singularity of the interaction at  $\mathbf{r} = 0$ , each graph is potentially ultraviolet divergent. Power counting suggests, however, that the integrals are finite. Suppose we cut off all momentum integrals at  $|\mathbf{p}| \approx \beta \gg 1$  and all frequency integrals at  $|\alpha| \approx \beta^2$ ; then the integration volume scales as  $\beta^{3(3m)+2(2k+3m)} = \beta^{4k+15m}$ . The  $m$  momentum and frequency delta functions scale as  $\beta^{-5m}$ , and the  $2k + 3m$  propagators scale as  $\beta^{-2(2k+3m)}$ . The *a priori* estimate (12) shows that  $\gamma^{(k+m)} \leq \beta^{-5(k+m)}$ . Since  $4k + 15m < 5m + 2(2k + 3m) + 5(k + m)$ , the integrals should be convergent in the ultraviolet regime  $\beta \gg 1$ . To make this argument rigorous, we use an integration scheme, dictated by the structure of the graph. We start by integrating the momenta and frequencies of the leaves; these integrals are convergent because of the *a priori* estimates (12), and they also provide a momentum decay on the lines adjacent to the leaves. We then iterate this procedure, integrating all momenta and frequencies by moving from the right to the left of the graph and transferring a suitable momentum decay.

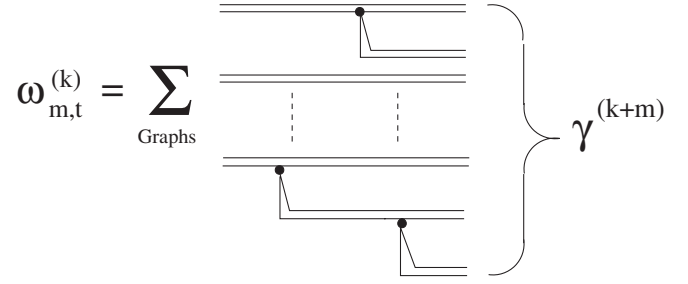

FIG. 1. Diagrammatic expansion for  $\omega_{m,t}^{(k)}$  as a sum of Feynman graphs with  $m$  vertices,  $2(k + m)$  leaves, and  $2k$  roots.

*Conclusion.*—We have proven that Bose-Einstein condensates evolve according to the Gross-Pitaevskii equation. This provides a mathematical description of recent experiments on the evolution of initially trapped condensates. On the theoretical level, it is surprising that the GP equation is correct even if the initial state is uncorrelated (product). Our result thus suggests that the many-body dynamics builds up correlations on the length scale  $\ell \approx 1/N$  in a very short time. Since the emergence of correlations reduces the local energy, one may ask what happens with the excess energy. Although we are not able to give a mathematically rigorous answer, we believe that the excess energy is transferred to incoherent excitations living on intermediate length scales  $\ell$ , with  $N^{-1} \ll \ell \ll 1$ . Since the macroscopic dynamics described by the GP equation is affected only by the structure of the wave function on length scales of  $O(1)$  and  $O(1/N)$ , these mesoscopic excitations have no influence on the evolution of the condensate.
