Abstract

Fibrinogen (Fg) has been recognized to play a central role in coagulation, inflammation and tissue regeneration. Several studies have used Fg deficient mice (Fg−/−) in comparison with heterozygous mice (Fg+/−) to point the proinflammatory role of Fg in diverse pathological conditions and disease states. Although Fg−/− mice are considered ‘normal’, plasma Fg is reduced to ~75% of the normal circulating levels present in wild type mice (Fg+/+). We report that this reduction in Fg protein production in the Fg−/− mice is enough to protect them from kidney ischemia reperfusion injury (IRI) as assessed by tubular injury, kidney dysfunction, necrosis, apoptosis and inflammatory immune cell infiltration. Mechanically, we observed binding of Fg to ICAM-1 in kidney tissues of Fg−/− mice at 24 h following IRI as compared to a complete absence of binding observed in the Fg+/− and Fg−/− mice. Raf-1 and ERK were highly activated as evident by significantly higher phosphorylation in the Fg+/− kidneys at 24 h following IRI as compared to Fg+/− and Fg−/− mice kidneys. On the other hand Cyclin D1 and pRb, indicating higher cell proliferation, were significantly increased in the Fg+/− and Fg−/− as compared to Fg+/− kidneys. These data suggest that Fg heterozygosity allows maintenance of a critical balance of Fg that enables regression of initial injury and promotes faster resolution of kidney damage.

Introduction

Fibrinogen (Fg) is a 340 kDa glycoprotein, a homodimer linked by disulfide bonds with each unit comprising of 3 distinct polypeptide chains (αA, βB and γγ) that are encoded by 3 separate genes (FGA, FGB and FGG) [1]. Apart from its prominent role in the coagulation cascade, Fg serves as an acute phase response protein by acting as a ligand for receptors expressed on cells recruited to the site of inflammation [2]. In humans, several polymorphisms have been described most of them clustered in the FgB gene [3] resulting in chronically elevated levels of Fg [4,5]. Hyperfibrinogenemia (characterized by high circulating plasma levels of Fg) is consistently associated with an increased risk of cardiovascular diseases [6]; conversely, afibrinogenemia causes severe hemorrhagic risks in affected patients [7]. This suggests the necessity to maintain a critical balance in the levels of Fg that is high enough to maintain adequate clot formation yet low enough to reduce its interactions with cellular receptors along with reducing the availability of fibrin matrices that act as centers of the immune system’s inflammatory response.

The contribution of Fg in disease pathophysiology of various organs has been studied using Fg deficient mice (Fg−/−) that lack the αA chain, which precludes assembly of functional circulating protein [8,9]. Fg deficient mice (Fg−/−) that lack the αA chain [8] have been shown to be protected from variety of injury/disease states such as atherosclerosis [10], colitis [11], crescentic glomerulonephritis [12], Duchenne muscular dystrophy [13], endotoxemia [14], fibrosis [15,16], multiple sclerosis [17], myocardial ischemia-reperfusion injury [18], ischemic neurodegeneration [19] and rheumatoid arthritis [20]. It should be noted that all of these studies used littermate Fg−/− mice as experimental controls and not as experimental groups for comparison. Although the Fg−/− mice do not show any symptoms of abnormal clotting and are are for all purposes ‘normal’ when compared to Fg−/− mice, the plasma level of the Fg protein is reduced to ~75% of the normal circulating levels present in wild type mice (Fg+/+) [9]. The reduction in Fg may not be significant enough to impair the coagulation cascade but could still suffice to alter the binding response to variable cellular receptors thereby transforming the immune system’s inflammatory response.

The objective of our study, therefore, was to evaluate the expression profile of Fg following kidney ischemia reperfusion injury (IRI) and to characterize the phenotype of the Fg−/− and Fg−/− mice against animals homozygous for the αA gene (Fg+/+) in the context of kidney IRI.

Methods

Ethics

All animal maintenance and treatment protocols were in compliance with the Guide for Care and Use of Laboratory
animals as adopted and promulgated by the National Institutes of
Health and were approved by the Harvard Medical School
Animal Care and Use Committees (IACUC).

**Animals**

Littermate male wild type (Fg+/+)
, heterozygous (Fg+/−) and
knock out (Fg−/−) mice for fibrinogen on BALB/c background
(25–29 g) were used for the experiment [9]. Dr. Jay L. Degen at
Children’s Hospital Research Foundation, Cincinnati, Ohio,
kindly provided breeding pairs of genetically modified Fg mice.
Neonate mice experience spontaneous bleeding events, which
proves fatal only in 30–50% of cases (depending on strain) and
those who survive display otherwise normal organ physiology [9].

**Experimental Design**

In the first set of experiments twenty male BALB/c mice were
anesthetized using pentobarbital sodium (30 mg/kg, ip) and
subjected to 25 min bilateral IRI [21] for characterization of
fibrinogen expression and excretion. Mice were sacrificed at 24, 48
and 72 hours after reperfusion (n = 5/timepoint). In the next set
of experiments genetically manipulated mice (54 male wild type,
heterozygous and knockout mice) were anesthetized as mentioned
above and subjected to 29 min of bilateral renal I/R surgery by
the retroperitoneal approach. Sham surgery was performed with
exposure of both kidneys but without induction of ischemia. Mice
(n = 6/group/timepoint) in the respective groups (sham or I/R)
were injected with BrdU (50 mg/kg, ip) 3 hr prior to sacrifice.
Mice were sacrificed at 12 and 24 h following reperfusion using
 overdose of pentobarbital (180 mg/kg, ip).

**Serum creatinine (Scr) concentrations and blood urea nitrogen
(BUN) were measured using a VetScan VS2 (Abaxis, Union City,
CA). Plasma Fg (D-Dimer) test was performed by Asserachrom
D-Di ELISA kit from Diagnostica Stago, Inc. ( Parsippany, NJ) as per
manufacturer’s instruction. Urinary Fg levels were measured using
commercially available Luminex assay based kit from Millipore
(Billerica, MA). Urinary creatinine concentration was used to
normalize fibrinogen in order to account for the influence of
urinary dilution.

**Real Time PCR**

Total RNA was extracted by TRIzol reagent (Invitrogen Corporation) as per manufacturer’s protocol. Forward and reverse
primer sequences for mouse specific genes were designed using
MacVector software (MacVector Inc., Cary, NC) and are listed in
Table S1.

**In situ Hybridization**

Kidney, liver and heart cryosections were washed with TBS and
in situ hybridization was performed with universal digoxigenin
based in situ hybridization and detection kit as per manufacturer’s
instructions (Invitrogen, Carlsbad, CA). The probe sequences used
are as follows: Fgα-AAT ATG CAA AGA TAG GCA TCA CCC
AGA TGA AAG TAG CTA CTG CCG ACC TGC CTG C; Fgβ-AGT ATA CTC TGT ACG GCT GTA TGG AGG TGT
CAG GCT GGA TGA GAT AGA TTT CGG A; Fgα-CTG AGT
GCA TAT GGA ATT GTG GAC TGC ATG CTT ATC AAA
TGA ATC TTC TCA TTT C.

**Immunofluorescence Staining**

Immunostainings in the frozen kidney sections was performed
using rat monoclonal anti-F4/80 a kind gift from Dr. Bonventre’s
laboratory, BWH, Boston, MA and rat monoclonal anti-BrdU
(Cell Signaling Technology, Danvers, MA). The primary antibody
was detected using donkey anti rat Cy3 labeled and donkey anti
rat FITC labeled secondary antibodies respectively (Jackson
Immunoresearch Laboratories, West Grove, PA). DAPI (Sigma
Aldrich, St. Louis, MO) was used for nuclear staining. Apoptosis
was measured in kidney tissues by TUNEL assay using the In Situ
Cell Death detection kit (Roche Applied Science) according to
manufacturer’s instructions [22]. The images were captured by
Nikon DS-Qi1Me camera attached to Nikon eclipse 90i fluores-
cence microscope using oil immersion objective 60/1.4 NA by
Nikon NIS elements AR ver 3.2 software.

**Fibrinogen Heterozygosity in Kidney Damage**

Kidney tissues were homogenized in RIPA buffer [50 mM Tris-
HCl pH 7.4, 150 mM NaCl, 1% NP40, 1 mM PMSF, 1 mM
NaF, 20 mM Na3P04, 2 mM Na2VO4, 1X protease inhibitor
cocktail (Roche Applied Science, Indianapolis, IN)] and equal
protein (30 μg) was resolved by polyacrylamide gel electrophoresis.
For plasma 0.02 μl was loaded on the gel. Proteins were
transferred onto nitrocellulose membrane and western blotting
was performed with rabbit polyclonal anti-fibrinogen (Dako),
mouse monoclonal anti-pERK, anti-ERK2 (BD Biosciences San
Diego, CA), anti-Cyclin D1, anti-pRb, anti-β -Actin (Cell
Signaling Technology), anti-i-Tubulin (Sigma) and goat polycl-
onal HRP conjugated anti-mouse albumin (Abcam, Cambridge,
MA). HRP conjugated secondary antibodies against mouse, rabbit
and goat was purchased from Jackson Immunoresearch (West
Grove, PA). For Immunoprecipitation (IP) tissues were lysed in IP
buffer (20 mM Tris-HCl pH 8.0, 137 mM NaCl, 10% glycerol,
1% NP-40, 2 mM EDTA) containing protease inhibitor cocktail
(Roche Applied Science, Indianapolis, IN) and equal
protein was incubated overnight at 4°C with 4 μg of rabbit
polyclonal anti-fibrinogen antibody (Dako), Fifty microlitre
of protein A/G agarose was added and incubated for 2 h at room
temperature. Beads were washed thrice with IP buffer. Immune
complex was eluted by adding 1X SDS loading dye and heating at
100°C and western blot was performed to detect ICAM-1 (goat
polyclonal, R&D Systems) and goat polyclonal anti-fibrinogen
(Nordic lab, The Netherlands).

**Statistics**

Data are expressed as average ± standard error. Statistical
difference (p<0.05) as calculated by one-way ANOVA or student’s
t-test. P<0.05 was considered significant and represented by ‘*’ as
compared to shams, ‘*’ as compared to wild type at similar time
points, ‘#’ as compared to heterozygous at similar time points
where applicable. All graphs were generated by GraphPad Prism
(GraphPad, Inc., La Jolla, CA).

**Results**

We found a significant increase in the mRNA (Fig. 1A, 1B), protein
expression (Fig. 1C) of Fg (Fgα, Fgβ and Fgγ) in the kidney
and urinary excretion of Fg (Fig. 1D) in mice following IRI
regarding to the kidney dysfunction and proximal tubular
necrosis (Fig. S1). In situ hybridization (ISH) with Fgα, Fgβ and Fgγ
in the liver tissue revealed strong diffuse cytoplasmic staining in the
hepatocytes (Fig. 1B, biological positive control). In the kidney,
the staining varied in intensity and distribution between the chains
and with respect to the presence or absence of injury (Fig. 1B, first
two columns). Fgα in uninjured (sham) kidney revealed diffuse
cytoplasmic staining that was less intense than the reactivity in
liver under the same conditions. The staining was more intense
and perinuclear in distribution 24 h after IRI. The staining was
more intense and perinuclear in distribution 24 h after IRI. ISH
for Fgβ in uninjured kidney was as intense as in liver, but revealed
more intense diffuse cytoplasmic distribution at 24 h. ISH for Fg\(^{a}\) was of similar reactivity to Fg\(^{a}\) in distribution and intensity, in uninjured and injured kidney; there was more diffuse cytoplasmic staining in uninjured tissue, with less intense reactivity when compared to the liver tissue, but in IRI, the reactivity intensified and distributed around the nuclei, similar to the Fg\(^{a}\).

Phenotypically the Fg\(^{a+/}\) and mutant mice for Fg4-\(\alpha\) chain [heterozygous (Fg\(^{a+/}\)) or knockout (Fg\(^{-/-}\))] demonstrated following features (Fig. S2A): i) loss of Fg\(^{a}\) chain with, albeit modestly decreased, but detectable transcription and translation of Fg\(\beta\) and Fg\(\gamma\) chains in the liver of Fg\(^{-/-}\) mice (Fig. S2B) as reported previously [9]; ii) significant decrease in transcription and translation of Fg\(^{a}\) and Fg\(\beta\) with no alterations in Fg\(\gamma\) chain in the kidney of Fg\(^{-/-}\) mice (Fig. S2C) as compared to Fg\(^{a+/}\) mice; iii) approximately 50% decrease in plasma Fg D-Dimer levels in IRI in mice (Fig. S2D); iv) unaltered urinary Fg protein excretion (Fig. S2E). Following IRI, Fg\(^{a+/}\) and Fg\(^{-/-}\) mice showed greater kidney dysfunction as assessed by BUN and SCr (Fig. 2A) at 12 h as compared to Fg\(^{a+/}\) mice (Fig. 2A). However, by 24 h the kidney dysfunction in the Fg\(^{a+/}\) and Fg\(^{-/-}\) mice further escalated whereas, the Fg\(^{a+/}\) mice appeared to show rapid functional restoration with BUN and SCr levels ~2–3 fold lower than the Fg\(^{a+/}\) and Fg\(^{-/-}\) mice (Fig. 2A). Urinary Fg, serving as a sensitive indicator of kidney tubular injury [21], also showed a massive increase at 12 h in all three groups but significantly reduced levels in Fg\(^{a+/}\) (−5-fold) and Fg\(^{-/-}\) (−10-fold) mice as compared to Fg\(^{a+/}\) mice (Fig. 2A). Kidney histology showed severe necrosis in the cortico-medullary junction of all post ischemic kidneys particularly in the S3 segments at 12 and 24 h (Fig. 2B). Although differences between the Fg\(^{a+/}\), Fg\(^{a+/}\) and Fg\(^{-/-}\) mice in the extent of necrosis were subtle, there was a marked reduction in the number of apoptotic cells at 24 h in the Fg\(^{a+/}\) and Fg\(^{-/-}\) mice as compared to Fg\(^{a+/}\) mice (Fig. 2C).

We next evaluated the contribution of inflammatory immune cell invasion in progression of kidney injury by immunostaining for markers of macrophage (F4/80) and neutrophil (Ly-6G) infiltration. The number of F4/80 positive cells was similar at 12 h in all three groups but at 24 h the Fg\(^{a+/}\) and Fg\(^{-/-}\) mice showed a statistically significant decrease in the number of macrophages (Fig. 3A) as well as Ly-6G positive neutrophils (Fig. 3B) as compared to Fg\(^{a+/}\) mice.

To evaluate the kidney tissue repair we quantitated the number of proliferating epithelial cells by BrdU immunostaining and found that Fg\(^{a+/}\) and Fg\(^{-/-}\) mice exhibited significantly greater number of BrdU positive cells as compared to Fg\(^{a+/}\) mice at 24 h (Fig. 3B). This suggests that although the initiation and early phase of injury was similar in all three groups there was a timely and efficient tissue repair response in the Fg\(^{a+/}\) and Fg\(^{-/-}\) mice, which curbed inflammation and apoptosis resulting in regression of injury. We hypothesized that in the Fg\(^{a+}\) mice there is progression of the initial injury because of Fg binding to Intercellular Adhesion Molecule-1 (ICAM-1) that promotes apoptosis and cell death through ERK phosphorylation.

We found that there was significant binding of Fg to ICAM-1 in kidney tissues of Fg\(^{a+/}\) mice at 24 h following IRI as compared to a complete absence of binding observed in the Fg\(^{a+/}\) and Fg\(^{-/-}\) mice (Fig. 4A). Consistently there was a significant decrease in expression of Fg protein at 24 h in Fg\(^{a+/}\) and Fg\(^{-/-}\) mice kidneys as compared to Fg\(^{a+/}\) mice following IRI (Fig. 4B). We further confirmed Fg binding to ICAM-1 in tubular epithelial cells by co-immunostaining that showed a Pearson co-localization coefficient between Fg and ICAM-1 to be 0.6 in Fg\(^{a+/}\) as compared to 0.4 and 0.05 in Fg\(^{a+/}\) and Fg\(^{-/-}\) respectively (Fig. S4). Raf-1 and ERK were highly activated as evident by significantly higher phosphorylation in the Fg\(^{a+/}\) kidneys at 24 h following IRI as compared to Fg\(^{a+/}\) and Fg\(^{-/-}\) mice kidneys. pERK was upregulated at 12 h in all three groups confirming the earlier observations (Fig. 2) about similar level of necrosis, apoptosis and

Figure 1. Transcription and translation of Fg\(\alpha\) Fg\(\beta\) and Fg\(\gamma\) in the kidney as urinary Fg excretion is significantly increased following IRI in mice. A) To characterize the de novo expression of Fg\(\alpha\) at the mRNA and protein level in the kidney, male BALB/c were subjected to IRI and kidneys, blood and urines were collected over time (n = 5/time point). A) Real time PCR analysis in kidney for Fg\(\alpha\), Fg\(\beta\) and Fg\(\gamma\) chain, normalized to GAPDH, and fold change determined over sham. B) In situ hybridization for Fgs, Fg\(\beta\) and Fg\(\gamma\) mRNA in kidney, 1:25 represents competition with unlabeled probe, liver (positive control) and heart (negative control). C) Western blot analysis for Fg protein in the kidney. β-Actin served as loading control. D) Urinary Fg levels measured by Luminex assay. *represents p<0.05 as determined by student’s t-test as compared to sham. Bar represents 10 μm. doi:10.1371/journal.pone.0045628.g001
inflammation at 12 h in the three groups of mice. On the other hand Cyclin D1 and pRb, indicating higher cell proliferation, were significantly greater at 24 h in the Fg\textsuperscript{+}/\textsuperscript{+} and Fg\textsuperscript{2}/\textsuperscript{2} as compared to Fg\textsuperscript{+}/\textsuperscript{+} kidneys (Fig. 4B).

**Discussion**

Our results support the hypothesis that a reduction in availability of excess Fg from interacting with ICAM-1 prevents progression of injury thereby allowing timely induction of Cyclin D1 and pRb mediating efficient kidney tissue repair and resolution of injury (Fig. 4C). This hypothesis is consistent with the previous reports demonstrating therapeutic potential of Fg-derived peptides (B\textsubscript{B15–42} and \texteta\textsubscript{377–395}) by competing with native Fg for binding to vascular endothelial cadherin (VE-cadherin), ICAM-1, CD11b/CD18 which in turn inhibits infiltration of leukocytes at the site of injury and prevents exacerbation of injury [18,23]. Furthermore, others and we have previously shown that B\textsubscript{B15–42} peptide administration protected from kidney IRI by increasing tissue repair and decreasing apoptosis [21,24] confirming that pharmacological reduction in excess Fg paves the way for faster structural and functional recovery.
Figure 3. Heterozygous and knockout Fg mice exhibit efficient immune cell clearance coupled with robust tubular epithelial cell proliferation. Fixed frozen sections following IRI were stained for A) macrophage F4/80 (red). Number of F4/80 cells per 60X field is represented graphically on the right of the photomicrograph. B) BrdU positive cells (green) by immunofluorescence. Percentage of positive staining for BrdU positive nuclei is represented graphically on the right of photomicrographs. Arrowheads indicate positive cells/nucleus and bar represents 10 μm.

doi:10.1371/journal.pone.0045628.g003
Figure 4. Fibrinogen binds to ICAM-1 in the kidney leading to sustained tissue injury. A) Kidney tissue lysates were immunoprecipitated with anti-fibrinogen antibody and immunoblot was performed for ICAM-1. IgG light chain served as loading control for IP and β-Actin served as loading control for input. B) Following 29 min IRI kidney tissue lysates were prepared and equal protein was resolved on SDS-PAGE for western blot analysis for pERK, ERK, Cyclin D1 and pRb. α-Tubulin served as loading control. C) Schematic showing that in the Fg+/− mice a reduction in availability of excess Fg from interacting with ICAM-1 prevents progression of injury thereby allowing timely induction of Cyclin D1 and pRb mediating efficient kidney tissue repair and resolution of injury.

doi:10.1371/journal.pone.0045628.g004
Thus, the new findings of this study are i) Fg (Fgα, Fgβ, and Fgγ) is transcribed in the kidney and its mRNA levels, protein expression and urinary excretion significantly increase following IRI; ii) Heterozygosity of mouse Fgα chain results in global reduction of Fg production to a moderate level that protects the Fg−/− mice from IRI-induced kidney tubular injury, kidney dysfunction, inflammation and apoptosis by launching an efficient tissue regeneration response. Although Fg−/− mice showed a reduction in apoptosis, reduced immune cell infiltration and increased regeneration, the functional and structural restoration of the kidney after IRI was not as rapid as Fg+/− mice potentially due to the impedance with clotting.

Fibrinogen binding to ICAM-1 through its γ117-132 domain has been well documented on endothelial cells [25,26] and has been shown to promote leukocyte transmigration by acting as an intermediary molecule that can bind both ICAM-1 and leukocytes through the Mac-1 receptor [27]. We extended these studies and show that Fg binds to ICAM-1 in the kidney following IRI thereby potentially activating Raf-1, triggering the Raf-MEK-ERK pathway, which in turn can activate an apoptotic response. Experiments using anti-ICAM-1 antibodies as well as ICAM-1–deficient mice have shown ICAM-1 to be a key mediator of acute IRI injury via potentiation of neutrophil–endothelial interactions [28]. ICAM-1 expression significantly increases on proximal tubular epithelial cells in patients with acute renal allograft rejection [29] and here we found significant co-localization of ICAM-1 with Fg (Pearson’s co-localization coefficient of 0.6, Fig. S4) predominantly on the proximal tubular epithelial cells emphasizing the paradigm that tubular epithelium is not merely a passive victim of injury but also an active participant in the inflammatory response in kidney IRI [30].

In summary, our experiment shows that kidney expresses Fgα, Fgβ and Fgγ transcripts and genetic manipulation resulting in decreased availability of Fg protein to interact with cellular receptors diminishes the molecular response cascade and dampens the inflammatory response leading to faster resolution of injury.
