INTRODUCTION

The V-ATPase is a multisubunit complex that transports protons across membranes. Mutations of its B1 or a4 subunit are associated with distal renal tubular acidosis and deafness. In the kidney, the a4 subunit is expressed in intercalated cells of the distal nephron, where the V-ATPase controls acid/base secretion, and in proximal tubule cells, where its role is less clear. Here, we report that a4 KO mice suffer not only from severe acidosis but also from proximal tubule dysfunction with defective endocytic trafficking, proteinuria, phosphaturia and accumulation of lysosomal material and we provide evidence that these findings may be also relevant in patients. In the inner ear, the a4 subunit co-localized with pendrin at the apical side of epithelial cells lining the endolymphatic sac. As a4 KO mice were profoundly deaf and displayed enlarged endolymphatic fluid compartments mirroring the alterations in pendrin KO mice, we propose that pendrin and the proton pump co-operate in endolymph homeostasis. Thus, our mouse model gives new insights into the divergent functions of the V-ATPase and the pathophysiology of a4-related symptoms.
A–H (denoted in capital letters), and the membrane-bound V0 domain of subunits a, d and c with several copies of the c subunit. For some subunits, there are various isoforms and the subunit composition can differ considerably between various sites of expression. Even in any single cell type, different isoforms of a particular subunit can be present in various subcellular structures (Marshansky & Futai, 2008).

Atp6v0a4 in kidney and inner ear

**Figure 1.** Disruption of the a4 subunit in mice results in early mortality.

A. Cartoon of the V-ATPase with its transmembrane (V0) and peripheral (V1) sector, each build up by different subunits. The V0 sector including the a subunit is highlighted in orange.

B. Partial genomic structure of the Atp6v0a4 gene (top) and the targeted a4 locus. The dotted line indicates the genomic sequence included in the targeting construct. A neomycin selection cassette flanked by frt sites (black boxes) and single loxP site was inserted into intron 11. A second loxP site and a BamHI site were introduced into intron 10. Correctly targeted ES cell clones were used for the generation of chimeric mice (below). a4 KO mice were generated by breeding chimeric mice to a cre-deleter mouse strain (bottom).

C. a4 transcript abundance in kidneys of Atp6v0a4+/+ (WT), Atp6v0a4+/− (Het) and Atp6v0a4−/− (KO) mice as revealed by Northern blot. Gapdh mRNA served as a loading control.

D. Detection of the a4 subunit by Western blot analysis of kidney protein lysates of four individual mice per genotype; β-actin served as a loading control.

E. Significant reduction of body weight in Atp6v0a4−/− mice at 3 weeks of age (*p < 0.01).

F. Kaplan–Meier plot during early postnatal life. Atp6v0a4+/+ (n = 25) and Atp6v0a4−/− (n = 40) are viable. Atp6v0a4−/− mice (n = 23) have an increased mortality beginning at 19 days of age.
In most cell types, V-ATPase expression is restricted to intracellular membranes where it mediates acidification of the lumen of intracellular organelles including endosomal and lysosomal compartments. However, in some highly specialized cells such as osteoclasts (Lee et al, 1996), epididymal clear cells (Shum et al, 2009) or renal intercalated cells (ICs; Wagner et al, 2004) the V-ATPase is also expressed at the plasma membrane. In these cells, the V-ATPase mediates acidification of the extracellular space, a process critical for bone resorption, male fertility and renal acid secretion.

A defect of distal acid secretion is the leading symptom in autosomal recessive distal renal tubular acidosis (dRTA) and can be caused by mutations in the genes encoding either the ATP6V0B1 (B1) or the ATP6V0A4 (a4) subunit of the V-ATPase (Karet et al, 1999; Smith et al, 2000). Whereas in mammals two isoforms exist for the B subunit, which is part of the V1 domain, four different isoforms are known for the a subunit, which is an integral membrane protein of the V0 domain (Forgac, 2007). Some patients carrying mutations in either the ATP6V0A4 or the ATP6V1B1 gene also suffer from hearing impairment of variable degree (Stover et al, 2002; Vargas-Pousou et al, 2006).

Both subunits are heavily expressed in ICs (Schulz et al, 2007), which are found in renal connecting tubules as well as collecting ducts and are the main effectors of the fine regulation of renal acid/base homeostasis (Kim et al, 1999b). Whereas type A-ICs secrete acid apically via the V-ATPase and recover bicarbonate basolaterally via the Na+-independent anion-exchanger 1 (Ae1, Slc4a1), type B-ICs secrete bicarbonate apically via the Na+-independent anion-exchanger pendrin (Pds, Slc26a4) and express the V-ATPase at their basolateral side (Gu¨nther et al, 2003; Piwon et al, 2000), although recent V-ATPase (Marshansky et al, 2002; Marshansky & Futai, 2007) knockout mice failed to thrive resulting in a lower body weight (5.44 ± 0.26 g, n = 5) compared to WT (8.06 ± 0.50 g, n = 5; p < 0.01) and heterozygous littermates (7.97 ± 0.32 g, n = 6; p < 0.01; Fig 1E), and died within the first 3–5 weeks of life (Fig 1F). As described earlier, immunostainings for the a4 subunit labelled both proximal tubules as well as cortical and medullary collecting ducts (Supporting Information Fig S1A–C). At the light microscopy level, no gross alterations of the kidney of ATP6V0A4−/− mice were detected (Supporting Information Fig S2A–D).

RESULTS

Disruption of Atp6v0a4 in mice results in a severe phenotype with early mortality

To disrupt the ATP6V0A4 gene in mice, we deleted a fragment including exon 11 by loxP/Cre-mediated recombination (Fig 1B). At birth, heterozygous (ATP6V0A4+/−; Het) and homozygous (ATP6V0A4−/−; KO) knockout mice appeared indistinguishable from their wildtype (ATP6V0A4+/−; WT) littermates and were born from heterozygous matings at Mendelian ratio. Northern blot analysis of ATP6V0A4 transcript abundance of total RNA isolated from P21 kidneys from ATP6V0A4−/− mice suggested that the variant transcript was subjected to nonsense-mediated RNA decay (Fig 1C). The absence of the a4 protein from ATP6V0A4−/− kidney lysates was confirmed by Western blot analysis (Fig 1D). Homozygous knockout mice failed to thrive resulting in a lower body weight (5.44 ± 0.26 g, n = 5) compared to WT (8.06 ± 0.50 g, n = 5; p < 0.01) and heterozygous littermates (7.97 ± 0.32 g, n = 6; p < 0.01; Fig 1E), and died within the first 3–5 weeks of life (Fig 1F). As described earlier, immunostainings for the a4 subunit labelled both proximal tubules as well as cortical and medullary collecting ducts (Supporting Information Fig S1A–C). At the light microscopy level, no gross alterations of the kidney of ATP6V0A4−/− mice were detected (Supporting Information Fig S2A–D).

ATP6V0A4 deficiency leads to severe dRTA

In the collecting duct, the a4 subunit was expressed in ICs, where it co-localized with the E1 subunit of the V-ATPase (Fig 2A). The lack of labelling in KO kidney sections showed that the a4 antibody was specific (Fig 2B). In acid-secreting type A-ICs that were identified by their basolateral labelling for Ae1, the a4 staining was apical (Fig 2C), whereas it was basolateral in bicarbonate-secreting type B-ICs, which were labelled for pendrin (Fig 2D). In contrast to a previous report (Stehberger et al, 2003), we did not detect any specific labelling of the thick ascending limb or the connecting tubule (Supporting Information Fig S1A–C).

In humans, metabolic acidosis is defined by a blood pH < 7.38 associated with a decrease in plasma [HCO3−] (Morris & McSherry, 1972). In line with a major defect of renal proton secretion, blood gas analysis in ATP6V0A4−/− mice revealed a systemic pH of 6.89 ± 0.20 and a drastic reduction of plasma [HCO3−], whereas ATP6V0A4−/− mice exhibited a normal acid-base status like their WT littermates (Fig 2E–F and Table 1). Under the stimulus of systemic acidosis as observed in a4 KO mice, intact distal acid secretion should lead to maximally decreased urine pH values below pH 5.5. Hence, the urine pH of...
6.69 in a4 KO mice suggests a severe distal acidification defect. *Atp6v0a4*+/+ and *Atp6v0a4*−/− mice could efficiently secrete acid into the urine in response to metabolic acidification by adding 0.28 M NH₄Cl to the drinking water (Supporting Information Fig S3A–B), suggesting that the failure of *Atp6v0a4*−/− mice to increase the net acid/ammonium excretion reflected the absolute requirement of the a4 subunit for normal urine acidification but not the functional immaturity of the kidney at that age.

We next tested whether an adaptive response to metabolic acidosis of the collecting duct could be observed in the absence of the a4 subunit in order to increase proton secretion. Normally the V-ATPase is translocated from the cytoplasm to the apical plasma membrane of type A-ICs upon acidosis, whereas it is translocated from the basolateral plasma membrane to the cytoplasm in type B-ICs (Schwartz et al, 1985). In *Atp6v0a4*−/− mice, however, the immunostaining on tissue sections for the E1 (Fig 2B and Supporting Information Fig S4D) and the A subunit (Fig 2I and Supporting Information Fig S4B) was diffusely cytoplasmic, in striking contrast to the staining of the apical cell pole observed in *Atp6v0a4*+/+ mice (Fig 2A and H and Supporting Information Fig S4C and A). This mislocalization entailed a drastic down-regulation of the A, B1 and E1 subunit levels relative to WT as quantitatively determined in Western

Figure 2. Localization of the a4 subunit in the distal tubule and metabolic acidosis in a4 KO mice. For clarity the basolateral and apical borders of the tubular epithelium are indicated by dotted lines and the lumina are marked with an asterisk in immunofluorescence images.

blots of kidney lysates from \( n = 5 \) WT and \( n = 5 \) Atp6v0a4\(^{-/-}\) mice (A subunit WT: 1.00 ± 0.05, KO: 0.33 ± 0.07, \( p < 0.0001 \); B1 subunit WT: 1.00 ± 0.08, KO: 0.17 ± 0.02, \( p < 0.0001 \); E1 subunit WT: 1.000 ± 0.09, KO: 0.26 ± 0.07, \( p < 0.0001 \); Fig 2G). This suggests that the absence of the \( \alpha_4 \) subunit interferes with the expression or the stability of other V-ATPase subunits. This was further corroborated by immunogold labelling of the A subunit. It localized to the apical plasma membrane and intracellular vesicles of type A-ICs of WT mice, but was almost absent in Atp6v0a4\(^{-/-}\) mice (Fig 2J and K).

In response to metabolic acidosis, the total number of acid secretory A-ICs is expected to increase while a parallel decrease in base secreting B-ICs occurs, the total number of ICs being unchanged (Schwartz & Al-Awqati, 1986; Schwartz et al, 1985). Although we observed a dramatic reduction in the number of pendrin-positive cells, reflecting the expected decrease in type B-ICs in response to acidosis, there was no compensatory increase, but rather a decrease in the number of A1-positive ICs (Fig 3A–C). In Western blots of kidney lysates from \( n = 5 \) Atp6v0a4\(^{-/-}\) mice, pendrin was significantly reduced compared to WT (WT: 1.00 ± 0.07, KO: 0.08 ± 0.01; \( p < 0.0001 \); Fig 2G).

a3-, cathepsin D (CatD)- and ClC-7-positive vesicles in proximal tubule cells (Fig 4C–F and Supporting Information Fig S6A and B). In electron micrographs of proximal tubule cells, we observed considerable amounts of vesicular storage material in Atp6v0a4/C0/C0 mice compared to WT mice (Fig 4G and H; for an overview of whole proximal tubule sections see Supporting Information Fig S7A and B). An alteration of the lysosomal compartment was further corroborated by a robust up-regulation of the lysosomal V-ATPase a3 subunit in Western blot studies of kidney protein lysates (Fig 5A). To exclude systemic non-specific effects of the severe metabolic acidosis on the subcellular localization of lysosomes (Heuser, 1989), we also analysed the lysosomal compartment in Atp6v0a4/C0/C0 enterocytes of the small intestine, which are organized similarly to proximal tubule cells but lack the a4 subunit even in WT. We did not find any differences between WT and Atp6v0a4−/− mice (Supporting Information Fig S8A and B). Similarly arguing against a non-specific effect of acidosis on lysosomes, Western blots indicated that the abundance of the lysosomal V-ATPase a3 subunit was markedly increased even in heterozygous mice compared to controls (Supporting Information Fig S8C).

As shown in ICs, the immunoreactivity for the A subunit of the V-ATPase was changed in proximal tubule cells in Atp6v0a4−/− mice as well (Fig 4I and J). Together with its down-regulation (as quantified by Western analysis of kidney protein lysates) this indicated that the expression and/or assembly of the V-ATPase complex were severely perturbed.

in the absence of the a4 subunit. This was further corroborated by immunogold labelling for the A subunit in proximal tubule cells (Fig 4K and L). Whereas the immunogold labelling for the A subunit was drastically decreased, this analysis did not reveal any obvious structural alterations in the brush border membranes of the a4 subunit, the endolymphatic duct as well as the endolymphatic vascularis were compressed and the spiral limbus flattened with pendrin (Fig 6A–C). In E15 and P1 mice lacking the a4 subunit, the endolymphatic duct as well as the endolymphatic sac were enlarged (Fig 6D–E). An enlargement of the endolymphatic compartment and profound deafness

Disruption of Atp6v0a4 results in an enlargement of the endolympathic compartment and profound deafness

The V-ATPase is highly expressed in several cell types in the inner ear (Stankovic et al., 1997) and dRTA caused by a4 mutations in humans can be accompanied by hearing impairment (Stover et al, 2002; Vargas-Poussou et al, 2006). Therefore, we analysed the expression of the a4 subunit in the inner ear. At postnatal day P1, a4 was confined to the luminal side of epithelial cells of the endolymphatic sac, where it co-localized with pendrin (Fig 6A–C). In E15 and P1 mice lacking the a4 subunit, the endolymphatic duct as well as the endolymphatic sac were enlarged (Fig 6D–E). An enlargement of the endolympathic space was also evident in HE-stained sections of the inner ear of P18 Atp6v0a4−/− mice. In particular, the cochlear duct, the scala media and the scala vestibularis were massively dilated, whereas inner and outer hair cells as well as neurons of the spiral ganglion appeared to be preserved. Fibrocytes of the spiral ligament as well as the stria vascularis were compressed and the spiral limbus flattened (Fig 6F and G), findings that are reminiscent of inner ear malformations in pendrin KO mice and in deaf individuals.
carrying mutations in the gene encoding Pendrin (Everett et al., 2001). At P21, we did not detect a loss of inner and outer hair cells in phalloidin-stained whole mount specimens of the organ of Corti (Fig 6H and I), although the auditory brainstem responses to acoustic clicks (Fig 6J and L) showed that Atp6v0a4−/− mice were profoundly deaf at that age (WT: 43.67 ± 4.29 pe dB SPL (n = 6), KO: 133.25 ± 11.93 pe dB SPL (n = 5); p = 0.01).

F. Urinary phosphate levels are increased in a4 KO mice compared to WT mice (***p < 0.001).

DISCUSSION

Here, we show that mice with a targeted disruption of the a4 subunit displayed proximal tubule dysfunction and a severe defect of renal acid secretion. The co-localization of the a4 subunit with the E1 or A subunit of the V-ATPase suggested that it is directly involved in proton secretion by type A ICs. As a correlate of impaired acid secretion, the loss of the a4 subunit also entailed drastic morphological changes of type A-ICs with a marked reduction of specialized V-ATPase transporting vesicles.

The severity of metabolic acidosis upon a4 subunit disruption contrasted markedly with the very mild effects observed in mice with a disruption of the B1 subunit (Karet et al, 1999) which have been attributed to a partial compensation by the incorporation of the alternative B2 subunit isoform into the V-ATPase holoenzyme (Paunescu et al, 2007). On the contrary, the drastic decrease of the V-ATPase E1 or A subunits in Atp6v0a4−/− mice suggests that the expression and/or assembly and/or targeting of the V-ATPase is severely impaired in the absence of a4. Indeed, signals necessary to target the V-ATPase to different cellular destinations were localized to the aminoterminal domain of the a subunit (Kawasaki-Nishi et al, 2001). Moreover, our findings are in agreement with the observation that the knockdown of the a4 subunit in a breast cancer cell line could not be functionally compensated by an up-regulation of another V-ATPase subunit (Hinton et al, 2009).

One has to consider that loss of the a4 subunit may also affect proximal acid secretion, in contrast to the B1 subunit, which is not expressed in the proximal tubule (Nelson et al, 1992). Even though the V-ATPase is present in the apical membrane of proximal tubule cells, its role in urine acidification is still under debate. Physiological studies initially concluded that the V-ATPase may mediate up to 40% of proton secretion in this segment (Chan & Giebsch, 1981) and that the V-ATPase is up-regulated in response to metabolic acidosis (Chambrey et al, 1994), but subsequent studies emphasized the critical role of Nhe3 in this process. However, in the absence of suitable mouse models with a proximal tubule-specific deletion of the pump, the contribution of each protein to proximal urine acidification remains unknown. Reanalysis of clinical data revealed that patients carrying mutations in the a4 subunit were more severely affected as well in terms of age at diagnosis and severity of acidosis as compared to patients with mutations of the B1 subunit.

The defect of the V-type ATPase might also impair the function of type B-ICs, which secrete bicarbonate apically via pendrin and recover H+ basolaterally via the V-ATPase. As secretion of bicarbonate would be counterproductive in metabolic acidosis, the stark down-regulation of pendrin in Atp6v0a4−/− mice may be a consequence of metabolic acidosis. Recent evidence points to an involvement of pendrin together with the Na+-coupled anion-exchanger NDCBE in the reabsorption of NaCl (Leviel et al, 2010). Hence, the secondary down-regulation of pendrin may result in a loss of NaCl, a symptom, which often complicates dRTA in patients (Sebastian et al, 1971). Our data showing that patients with Atp6v0a4 mutations were diagnosed earlier, had a more severe metabolic acidosis and a higher frequency of dehydration episodes are
consistent with the severity of the phenotype observed in \(\text{Atp6v0a4}^{-/-}\) mice and support a role of the a4 subunit in NaCl reabsorption. However, because of the very early lethality of a4 disruption in mice it was not possible to carefully dissect the impact of the knockout on sodium balance and on vascular volume and blood pressure regulation in this work. This will require additional studies upon IC-specific deletion of the a4 subunit.

The proteinuria, phosphaturia and lysosomal defects in \(\text{Atp6v0a4}^{-/-}\) mice show that the a4 subunit is also crucial for normal proximal tubule function. In support of the clinical relevance of these findings, we identified a patient with a4-related dRTA who had initially been misdiagnosed with Dent’s disease because of pronounced proximal tubular proteinuria (\(\beta\)-2 microglobulinuria: \(17.11\,\text{mg/mmol of creatinine}\)) and global aminoaciduria. The partial overlap with the \(2\text{Cl}^-/\text{H}^+\) antiporter CIC-5 and the lack of co-localization with the lysosomal \(2\text{Cl}^-/\text{H}^+\) antiporter CIC-7 and Lamp1 suggest that the a4 subunit does not reside in lysosomes and late endosomes, but in earlier endocytic compartments. The abnormal localization of the A subunit of the V-type ATPase furthermore suggests that the assembly of the V-type ATPase is critically disturbed in the absence of the a4 subunit. This is likely to have various secondary effects on both upstream and downstream compartments of the

endocytic apparatus. The GTPase Arf6 and its cognate GDP/GTP exchange factor ARNO, which directly interact with different subunits of the V-ATPase, are a particularly striking example. Their recruitment from the cytosol to endosomal membranes is driven by V-ATPase-dependent intra-endosomal acidification (Hurtado-Lorenzo et al, 2006). Moreover, disturbing this interaction resulted in reduced endocytosis and prevented the delivery of endocytosed proteins from early to late endosomes, thus causing an accumulation of cargo in early endosomes and, ultimately, inhibition of endocytosis (Hurtado-Lorenzo et al, 2006). An acidification-independent role of the V0 domain in membrane fusion (Bayer et al, 2003; Peters et al, 2001) may also contribute to the defect of the degradative pathway. In Drosocephila melanogaster, loss-of-function mutations in a neuron-specific isoform of the a-subunit blocked synaptic vesicle fusion without affecting synaptic vesicle acidification (Hiesinger et al, 2005).

Western blot analysis demonstrated a drastic down-regulation of NaPi-IIa in the proximal tubule, although metabolic acidosis as such may increase NaPi-IIa protein levels (Murer & Biber, 2010). Apart from a trafficking defect, the down-regulation of NaPi-IIa may also result from abnormally high levels of urinary parathyroid hormone (PTH). As shown for CIC-5 KO mice (Piwon et al, 2000), impaired proximal tubular endocytosis can increase luminal levels of PTH, which in turn stimulates the internalization and degradation of NaPi-IIa. Surprisingly, and unlike CIC-5 KO mice (Piwon et al, 2000; Wartosch et al, 2009), Atp6v0a4−/− mice displayed an enlargement of the lysosomal compartment as demonstrated by an increased number of Lamp1-, CIC-7- or a3-positive vesicles and an accumulation of undegraded material in proximal tubule cells, findings that superficially resembled the alterations observed upon disruption of the lysosomal CIC-7 transporter (Wartosch et al, 2009). As the a4 subunit was not expressed in the lysosomal compartment, it is possible that the accumulation is caused by an abnormal lysosomal composition due to a sorting defect (Nielsen et al, 2007).

Hearing impairment in patients with dRTA related to either Atp6v0a4 or Atp6v1b1 mutations is variable both in terms of onset and severity. As mice with a disruption of the B1 subunit had normal hearing (Karet et al, 1999), we were surprised that mice lacking the a4 subunit were already profoundly deaf in their second week of life. At this time point, inner and outer hair cells as well as the neurons within the spiral ganglion appeared to be preserved, whereas the scala media was significantly enlarged. These latter findings resembled the alterations observed upon disruption of the lysosomal CIC-7 transporter (Wartosch et al, 2009). As the a4 subunit was not expressed in the lysosomal compartment, it is possible that the accumulation is caused by an abnormal lysosomal composition due to a sorting defect (Nielsen et al, 2007).

Materials and Methods

All animal experiments were approved by the Thüringer Landesamt für Lebensmittelsicherheit und Verbraucherschutz (TLV) in Germany. For genetic studies, written informed consent was obtained from the patients or their parents according to French legislation. Clinical data at diagnosis were obtained as a part of the aspects necessary for orientation of genetic studies and analysed retrospectively.

Generation of Atp6v0a4 deficient mice

A clone isolated from a 129/SvJ mouse genomic λ library (Stratagene, now Agilent, Santa Clara, CA, USA) was used to construct the targeting vector (Rust et al, 2007). An approximately 11 kb SalI/SpeI fragment including exons 10–13 of the Atp6v0a4 gene was cloned into the pcKO-V901 plasmid (Lexicon Genetics, The Woodlands, TX, USA) with a phosphoglycerate kinase (pgk) promoter-driven diphtheria toxin A cassette. A pgk promoter-driven neomycin resistance cassette flanked by frt sites and an additional loxP site was inserted into the AgeI site of intron 11. A second loxP site and an additional BamHI site were inserted into the Mulu site in intron 10. The construct was linearized with NotI and electrooporated into R1 mouse embryonic stem (ES) cells. Neomycin-resistant clones were analysed by Southern blot using BamHI and an external approximately 400-bp probe (NC_000072 Mus musculus chromosome 6, 38009912-38010276). Two correctly targeted ES cell clones were injected into C57BL/6 blastocysts to generate chimeras. Chimeric mice were mated to a cre-Deleter mouse strain to remove exon 11 and the selection cassette (Schwenk et al, 1995). Studies were performed in a mixed 129Sv/C57BL/6 background in the F4 and F5 generation. Genotypes were determined by PCR of tail biopsy DNA. For PCR genotyping, the forward primers F1 (5′-caagcctcgagatgaggtagt-3′), F2 (5′-ggtatctggaggctg-3′) and the reverse primer R1 (5′-ctcaacagaagccccctg-3′) were used in a single PCR mix. The primer pair F1/R1 amplified a 378-bp WT allele, and the primer pair F2/R1 a 275-bp KO allele.
Atp6v0a4 and catcctt-3 mice obtained water supplemented with 0.28M NH4Cl as drinking water. For acid loading, pCO2 were measured with the ABL77 pH/blood–gas analyser (Radiometer, Copenhagen, Denmark). Blood bicarbonate concentration was determined from pH and pCO2 using the Henderson–Hasselbalch equation. For analysis of clinical data revealed that a4-related dRTA patients were also more severely affected as compared to patients with mutations of the B1 subunit.

RESULTS:
To study the pathogenesis of a4-related dRTA, we disrupted the a4 subunit encoding gene Atp6u0a4 in mice. a4-deficient mice developed severe metabolic acidosis because of a distal acid secretion defect, which is in sharp contrast to the mild phenotype of mice devoid of the B1 subunit (Finberg et al, 2005). Indeed, re-analysis of clinical data revealed that a4-related dRTA patients were more severely affected as compared to patients with mutations of the B1 subunit.

In addition to the distal acid secretion defect, a4-deficient mice displayed phosphaturia, proteinuria and an impaired degradative pathway of proximal tubule cells with accumulation of lysosomal material. These findings indicate a severe dysfunction of the proximal tubule upon disruption of the a4 subunit, a ‘hidden’ pathology that we also identified in a patient suffering from a4-related dRTA initially misdiagnosed with Dent’s disease. In the inner ear, the a4 subunit co-localized with the anion-exchanger pendrin at the apical side of epithelial cells lining the endolymphatic sac. Moreover, mice devoid of the a4 subunit were profoundly deaf and displayed enlarged endolymph compartments, mirroring the alterations in mice with a targeted disruption of the anion-exchanger pendrin.

IMPACT:
Our study provides unique and novel insights into the mechanisms of metabolic acidosis and hearing loss caused by ATP6V0A4 mutations. It also reveals a previously unrecognized role for the a4 subunit in endocytic trafficking in epithelial cells of the proximal tubule. Thus, our findings require a revision of the current dogma that kidney disease in dRTA arises only from defects in the distal tubule.

Northern blot
The Atp6u0a4 3’ UTR probe was cloned by PCR using the forward primer 5’-tcaccttgctctgccat-3’ and reverse primer 5’-aaagtaagga-caccttt-3’. Northern blot analysis was performed as described previously (Hübner et al, 2001).

Renal function
3–4-week-old Atp6u0a4+/+ (WT, n = 5), Atp6u0a4+/− (Het, n = 6) and Atp6u0a4−/− (KO, n = 5) mice were explored for their renal function. Spot urine was collected and pH was measured with a pH microelectrode (Inlab Ultra-micro pH, Mettler, Viroflay, France). Urinary ammonium and creatinine concentrations were measured as described previously (Chambrey et al, 2005). Blood pH and pCO2 were measured with the ABL77 pH/blood–gas analyser (Radiometer, Copenhagen, Denmark). Blood bicarbonate concentration was calculated from pH and pCO2 using the Henderson–Hasselbalch equation. For acid loading n = 9 WT and n = 7 Het mice obtained water supplemented with 0.28M NH4Cl as drinking water.

Immunofluorescence
In general, all immunostainings were performed on sections of at least three independent mice per genotype if not indicated otherwise and only representative findings are presented in the figures. Kidneys were fixed by in vivo perfusion of 4% paraformaldehyde in phosphate buffered saline (1× PBS). Antigens were retrieved prior to the labelling procedure by heating the sections in 0.01 M Tris, 0.1 M EDTA buffer for 5 min at 96°C or 1% SDS in 1× PBS. Sections were stained as described (Boettger et al, 2002) and analysed with a confocal microscope (Leica TCS SPS, Wetzlar, Germany or Zeiss LSM 510 META, Göttingen, Germany). Inner ears were removed, post-fixed for 2 h in 4% PFA in 1× PBS and decalcified by 10% EDTA/1× PBS at 37°C overnight (decalcification of inner ears was done in mice > P2 only). For immunofluorescence 8 µm cryosections were cut and processed as described above. For

Immunogold staining and electron microscopy
For immunogold staining, small pieces of WT and a4 KO kidneys were dehydrated through a graded series of ethanol to 100% ethanol and then embedded in LR White resin (Electron Microscopy Sciences, Ft. Washington, PA, USA). Thin sections were incubated on drops of primary anti-V-ATPase (A-subunit, 1:200) antibody for 2 h. After rinsing with PBS, the grids were incubated on drops of goat anti-rabbit IgG coupled to 15 nm gold particles (Ted Pella, Redding, CA, USA) for 1 h. Following several rinses with distilled water, the grids were stained with 2% uranyl acetate for 10 min, rinsed in distilled water, and dried. Sections were examined in a JEM-1011 transmission electron microscope (JEOL Ltd, Tokyo, Japan). For conventional electron microscopy, some kidneys were fixed in 2.5% glutaraldehyde in 0.1 M cacodylate buffer, pH 7.4. They were post fixed for 1 h in 2% osmium tetroxide, stained en bloc with uranyl acetate, dehydrated in graded ethanol and embedded in Epon (Electron Microscopy Sciences, Ft. Washington, PA, USA). Thin sections were stained with uranyl acetate and lead citrate prior to examination.

The paper explained

PROBLEM:
Mutations in the gene encoding the a4 and the B1 subunit of the vacuolar-type H+-ATPase lead to dRTA and hearing loss of variable degree. Apart from metabolic acidosis, a significant number of dRTA patients also develop nephrocalcinosis, polyuria, dehydration and hypokalemia. Thus, dRTA patients share symptoms with patients suffering from Dent’s disease, which is a disorder of the proximal tubule caused by abnormal endosomal acidification. As the a4 subunit, in contrast to the B1 subunit, is also expressed in endosomes of the proximal tubule, we hypothesized that a defect of the a4 subunit might have consequences for proximal tubule function and thus contribute to the complex phenotype of some of the patients with dRTA.

RESULTS:
To study the pathogenesis of a4-related dRTA, we disrupted the a4 subunit encoding gene Atp6u0a4 in mice. a4-deficient mice developed severe metabolic acidosis because of a distal acid secretion defect, which is in sharp contrast to the mild phenotype of mice devoid of the B1 subunit (Finberg et al, 2005). Indeed, re-analysis of clinical data revealed that a4-related dRTA patients were also more severely affected as compared to patients with mutations of the B1 subunit.

In addition to the distal acid secretion defect, a4-deficient mice displayed phosphaturia, proteinuria and an impaired degradative pathway of proximal tubule cells with accumulation of lysosomal material. These findings indicate a severe dysfunction of the proximal tubule upon disruption of the a4 subunit, a ‘hidden’ pathology that we also identified in a patient suffering from a4-related dRTA initially misdiagnosed with Dent’s disease. In the inner ear, the a4 subunit co-localized with the anion-exchanger pendrin at the apical side of epithelial cells lining the endolymphatic sac. Moreover, mice devoid of the a4 subunit were profoundly deaf and displayed enlarged endolymph compartments, mirroring the alterations in mice with a targeted disruption of the anion-exchanger pendrin.

IMPACT:
Our study provides unique and novel insights into the mechanisms of metabolic acidosis and hearing loss caused by ATP6V0A4 mutations. It also reveals a previously unrecognized role for the a4 subunit in endocytic trafficking in epithelial cells of the proximal tubule. Thus, our findings require a revision of the current dogma that kidney disease in dRTA arises only from defects in the distal tubule.
phalloidin staining, basilar membranes of fixed inner ears were removed and stained with Alexa-555-conjugated phalloidin in 1× PBS/7%TX-100 for 20 min. Haematoxylin and eosin (HE) histology was performed on 8 μm paraffin sections following standard protocols.

**Intercalated cell type quantification**

Kidney sections from Atp6u0a4+/− and Atp6u0a4−/− mice were co-stained with either Ae1 or Atp6v1e1 (E subunit of the V1 domain) or pendrin and E1, respectively. Randomly photographed cortex areas (n=12 fields) were analysed for co-expressing cells by blinded experimenters and the total number of ICs was calculated with standard error as the sum of both sub-populations. For the quantification of intracellular vesicles and mitochondria in ICs at least 10 cross-sections from ICs of two different mice per genotype were evaluated.

**Western blot analysis**

Isolated kidneys were homogenized in isolation buffer (250 mM sucrose, 20 mM Tris–Hepes, pH 7.4) containing a protease inhibitor cocktail (Roche Diagnostics, Risch, Switzerland). After removal of cell debris the kidney lysates were centrifuged at 17,000 g at 4°C for 30 min and the membrane proteins resuspended in isolation buffer. Protein concentration was determined using the Bradford protein assay (Bio-Rad Laboratories, Hercules, CA, USA). For Western blotting 10–60 μg protein was solubilized in SDS-loading buffer (62.5 mM Tris–HCl, pH 6.8, 2% SDS, 100 mM dithiotreitol, 10% glycerol and bromophenol blue) and incubated at room temperature for 30 min. Proteins were separated on reducing 7.5% SDS–polyacrylamide gels (bromophenol blue) and incubated at room temperature for 30 min and the membrane proteins resuspended in isolation buffer. Protein concentration was determined using the Bradford protein assay (Bio-Rad Laboratories, Hercules, CA, USA). For Western blotting 10–60 μg protein was solubilized in SDS-loading buffer (62.5 mM Tris–HCl, pH 6.8, 2% SDS, 100 mM dithiotreitol, 10% glycerol and bromophenol blue) and incubated at room temperature for 30 min. Proteins were separated on reducing 7.5% SDS–polyacrylamide gels and loading controls were performed as described (Quentin et al, 2001). For Western blot of spot urine, urine samples were normalized to urine creatinine values. Briefly, urine resuspended in SDS loading buffer was resolved on a 7.5% polyacrylamide gel in Tris–gycine buffer and in gel protein staining was carried out with Coomassie Blue (Euromedex, Souffelweyersheim, France).

**Urine albumin measurements**

To detect mouse albumin spot urine samples from n=7 WT and n=5 KO mice were analysed by an enzyme-linked immunosorbent assay (ELISA) against mouse albumin (AssayMax Mouse albumin ELISA Kit, AssayPro, St. Charles, MO, USA) according to the instructions of the manufacturer. The measurement was repeated twice.

**Antibodies**

*Primary antibodies:* guinea pig anti-mouse Ae1 (Steberberger et al, 2007) (1:5000), rabbit guinea pig anti-mouse Atp6v0a3 (Lange et al, 2006) (1:100), rabbit anti-human Atp6v0a4 (Steberberger et al, 2003; 1:500), rabbit anti-mouse Atp6v1b1 (Vallet et al, 2006; 1:30,000), chicken anti-Atp6v1e1 (1:500; Breton et al, 2000), rabbit anti-CIC-5 (Günter et al, 1998; PEPSE, 1:100), rabbit anti-mouse CIC-7 (Kornak et al, 2001; 7N48, 1:100), rat anti-mouse Lamp1 (BD Biosciences, 1:250), rabbit anti-rat Na+/P+ cotransporter 2α (NaPi-Ⅱa, gift of J. Biber, Zürich, Switzerland, 1:1000), rabbit anti-rat Nhe3 (Kim et al, 1999a; 1:5000), guinea pig anti-mouse pendrin (Hafner et al, 2008; 1:1000), mouse anti-human Villin (Acris, Herford, Germany, 1:200), sheep anti-human albumin (Biotrend Chemikalien, Cologne, Germany, 1:100) mouse anti-human β-actin (Sigma–Aldrich, St. Louis, MO, USA, 1:50,000).

*Secondary antibodies for immunofluorescence:* goat anti-rabbit coupled with Alexa 555 (Invitrogen, Karlsruhe, Germany 1:2000), goat anti-chicken coupled to Alexa 488 dye (Invitrogen, Karlsruhe, Germany, 1:800), donkey anti-guinea pig Cy5 (Jackson laboratories, 1:800), DAPI (Invitrogen, Karlsruhe, Germany).

*Secondary antibodies for Western Blotting:* goat anti-rabbit (Bio-Rad Laboratories, Hercules, CA, USA, 1:10,000), goat anti-mouse (Bio-Rad Laboratories, Hercules, CA, USA, 1:10,000), goat anti-guinea pig (Jackson Laboratories, West Grove, PA, USA, 1:1,000).

**Statistics**

Unless otherwise indicated, statistical significance was tested with Student’s t test and the mean values are given with SEM.

**Author contribution**

JCH and AKH generated Atp6u0a4−/− mice; JCH: initial characterization and Northern Blot; NP: Western Blot; NP and JCH: blood and urine analysis; NP, TS and AKH: immunofluorescence; DB: ultrastructural analysis and some immunofluorescence; AKH: inner ear analysis; HM: ABR experiments; RVP: patient genetic and clinical analysis; TJJ: advise on experiments and manuscript; CAH and DE initiated the study, planned experiments and wrote the paper. All authors commented on the manuscript.

**Acknowledgements**

We thank Katrin Schorr for excellent technical assistance and blastocyst injection, Peg McLaughlin for expert help with the immunogold EM and Robert Tyszkowski and Nicole Krönke for help with the immunofluorescence. This study was mainly funded by a grant of the DFG to CAH (Hu 800/7-1). Dominique Eladari is funded by INSERM, CNRS, by grant “HYPERCLO” ANR BLANC 2010-R10164DD from l’Agence Nationale de la Recherche (ANR) and by the grant ‘subvention de recherche 2011’ from the ‘association pour l’information et la recherche sur les maladies rénales génétiques (AIRG)’. Nicolas Picard is funded by a postdoctoral fellowship from l’ANR and by a grant ‘subvention de Recherche 2011’ from La Société Française d’Hypertension Artérielle (SFHTA). This study was further supported by a grant from the National Institutes of Health to DB (DK42956). The Microscopy Core Facility of the Program in Membrane Biology receives additional support from the Boston Area Diabetes and Endocrinology Research Center (NIH DK-57521) and from the Center for the Study of Inflammatory Bowel Disease (NIH DK-43351). Rosa Vargas-Poussou was supported by funds from The French Ministry of Health (Plan Maladies Rares), and the European Community FP7 (EUNEFRON, 201590). We thank the French Tubulopathy Network for support and Carsten Wagner for providing antibodies.
