ABSTRACT

Transient receptor potential vanilloid 1 (TRPV1) is a molecular pain receptor belonging to the transient receptor potential (TRP) superfamily of non-selective cation channels. As a polymodal receptor, TRPV1 responds to heat and a wide range of chemical stimuli. The influx of calcium following channel activation serves as a negative feedback mechanism leading to TRPV1 desensitization. The cellular calcium sensor calmodulin (CaM) likely participates in the desensitization of TRPV1. Two CaM binding sites are identified in TRPV1: the N-terminal ankyrin repeat domain (ARD) and a short distal C-terminal segment. Here we present the crystal structure of calcium-bound CaM (Ca\(^{2+}\)-CaM) in complex with the TRPV1 C-terminal (CT) segment, determined to 1.95 Å resolution. The two lobes of Ca\(^{2+}\)-CaM wrap around a helical TRPV1-CT segment in an anti-parallel orientation, and two hydrophobic anchors, W787 and L796, contact the C-lobe and N-lobe of Ca\(^{2+}\)-CaM, respectively. This structure is similar to canonical Ca\(^{2+}\)-CaM peptide complexes, although TRPV1 contains no classical CaM recognition sequence motif. Using structural and mutational studies, we established the TRPV1 C-terminus as a high affinity Ca\(^{2+}\)-CaM binding site in both the isolated TRPV1 C-terminus and in full-length TRPV1. Although a ternary complex of CaM, TRPV1-ARD and TRPV1-CT had previously been postulated, we found no biochemical evidence of such a complex. In electrophysiology studies, mutation of the Ca\(^{2+}\)-CaM binding site on TRPV1-ARD abolished desensitization in response to repeated application of capsaicin, whereas mutation of the Ca\(^{2+}\)-CaM binding site in TRPV1-CT led to a more subtle phenotype of slowed and reduced TRPV1 desensitization. In summary, our results show that the TRPV1-ARD is an important mediator of TRPV1 desensitization, whereas TRPV1-CT has higher affinity for CaM and is likely involved in separate regulatory mechanisms.
Keywords: Calcium / Calmodulin / Desensitization / TRPV1 / TRP channel
INTRODUCTION

TRPV1 is well recognized as a polymodal molecular pain receptor responding to a wide range of stimuli including noxious heat >43°C, chemical agonists and protons (Caterina et al., 1997; Tominaga et al., 1998). TRPV1 responses to these stimuli signal the exposure to extreme temperature or tissue damage to elicit appropriate protective mechanisms. TRPV1 is well characterized for its activation by capsaicin, a naturally occurring compound found in chili peppers (Caterina et al., 1997). Prolonged activation of TRPV1 with capsaicin results in acute desensitization, where TRPV1 activity decreases during the course of stimulation. In contrast, repeated stimulation of TRPV1 results in tachyphylaxis where TRPV1 activation decreases with successive stimulation followed by loss of response to any subsequent stimuli.

TRPV1 belongs to the transient receptor potential (TRP) superfamily of non-selective cation channels with high relative permeability for Ca^{2+} (Caterina et al., 1997). All TRP channels share a similar topology comprising six predicted helical transmembrane segments (S1-S6), and large N- and C-terminal cytosolic regions for integrating cellular signaling with channel activity (Gaudet, 2008). The N-terminal region of TRPV1 contains an ankyrin repeat domain (ARD), of which a structure is available (Lishko et al., 2007). The cytoplasmic C-terminus, of unknown structure, contains multiple sites for interactions with modulatory factors. TRPV1 functions as a tetramer, with S5-S6 forming the pore through which ion conduction occurs. Opening of TRPV1 following channel activation allows the influx of cations, including Ca^{2+}, into the cell.

The intracellular Ca^{2+} concentration is kept as low as 10^{-7} M in contrast to a high external Ca^{2+} concentration up to 10^{-3} M (Yamniuk and Vogel, 2004). The steep Ca^{2+} concentration gradient across the membrane in combination with the high relative permeability of TRPV1 for Ca^{2+} ensures rapid Ca^{2+} influx into the cells upon TRPV1 activation. However, intracellular
calcium homeostasis is crucial for normal cell function (Han et al., 2007), and continuous capsaicin activation of cells expressing TRPV1 or stimulation of TRPV1 with the potent agonist resiniferatoxin results in severe cytotoxicity and cell death (Caterina et al., 1997; Karai et al., 2004). Ca\(^{2+}\) ions are involved in various cellular processes, including several Ca\(^{2+}\)-dependent desensitization mechanisms identified for TRPV1. One is the Ca\(^{2+}\)-dependent recruitment of the calcineurin phosphatase to TRPV1 via a scaffolding protein, promoting the dephosphorylation and dampening of TRPV1 activity (Docherty et al., 1996; Mohapatra and Nau, 2005; Zhang et al., 2008). Similarly, Ca\(^{2+}\)-dependent stimulation of phospholipase C (PLC) may promote cleavage of the sensitizing agent PIP\(_2\) (Liu et al., 2005; Stein et al., 2006; Lishko et al., 2007; Lukacs et al., 2007; Yao and Qin, 2009; Mercado et al., 2010). Although depletion of PIP\(_2\) is thought to play a major role in desensitization (Lukacs et al., 2007; Mercado et al., 2010), artificial depletion of PIP\(_2\) does not completely reproduce the near full desensitization observed in the presence of calcium (Lukacs et al., 2007).

A third proposed mechanism is the inactivation of TRPV1 via interactions with Ca\(^{2+}\)-CaM (Numazaki et al., 2003; Rosenbaum et al., 2004; Lishko et al., 2007; Grycova et al., 2008). CaM is a ubiquitous and highly conserved 17 kD protein. It comprises two globular domains, the N and C-lobes, connected by a central flexible linker that allows CaM to assume different conformations (Barbato et al., 1992; Tjandra et al., 1995). Each lobe contains two helix-loop-helix Ca\(^{2+}\)-binding motifs known as EF hands and can thus bind four Ca\(^{2+}\) ions (Vetter and Leclerc, 2003). Apo-CaM and Ca\(^{2+}\)-CaM interact differently with many proteins including ion channels (Gordon-Shaag et al., 2008), making them versatile modulators of various proteins. CaM exhibits diverse mechanisms, sometimes acting through multiple sites, as shown for several
TRP channels (Zhu, 2005); its target recognition mechanisms are nearly as promiscuous as its functions (Hoeflich and Ikura, 2002; Yamniuk and Vogel, 2004).

Although TRPV1 does not have a recognizable CaM binding motif (Rhoads and Friedberg, 1997), at least two CaM binding sites have been identified in TRPV1 cytosolic domains. In vitro studies demonstrated that Ca\textsuperscript{2+}-CaM binds isolated TRPV1 peptides from the TRPV1-ARD (Rosenbaum et al., 2004). In addition, Ca\textsuperscript{2+}-CaM competes for a shared binding site on TRPV1-ARD with ATP, which sensitizes the channel to capsaicin and prevents tachyphylaxis (Lishko et al., 2007). A second CaM binding site was localized to a short 35-residue segment in the C-terminus of TRPV1 (TRPV1-CT) through in vitro binding assays (Numazaki et al., 2003). Deletion of this segment disrupts desensitization of TRPV1 to repeated stimulation by capsaicin. Furthermore, several mutations to positively charged residues within this region decreased the Ca\textsuperscript{2+}-CaM binding affinity of TRPV1-CT (Grycova et al., 2008). It is unclear how Ca\textsuperscript{2+}-CaM participates in desensitization of TRPV1 through its putative CaM binding sites. It has been postulated that Ca\textsuperscript{2+}-CaM may bridge the two sites, leading to a closed channel (Lishko et al., 2007).

Here, we present the first structural view of Ca\textsuperscript{2+}-CaM in complex with the 35-residue CaM-binding peptide from the TRPV1-CT (TRPV1-CT35: residues 767-801). Despite the absence of a classical CaM recognition motif, the complex is supported by hydrophobic anchors and electrostatic interactions similar to well-characterized Ca\textsuperscript{2+}-CaM peptide complexes. Our in vitro binding studies revealed that the C-lobe of Ca\textsuperscript{2+}-CaM is the major determinant of binding to either TRPV1-CT or TRPV1-ARD. We examined whether Ca\textsuperscript{2+}-CaM can bridge contacts between TRPV1-ARD and TRPV1-CT35, but our results do not support such a ternary complex. We used mutations that disrupt Ca\textsuperscript{2+}-CaM binding at either TRPV1-ARD (K155A) or TRPV1-ARD.
CT (W787A) to show that the W787A TRPV1 mutant is sufficient to disrupt the interaction of Ca^{2+}-CaM with full-length TRPV1, consistent with our *in vitro* observation that the TRPV1-CT is a high affinity binding site, with $K_D = 5.4 \pm 0.6 \times 10^{-8}$ M. Finally, while the K155A mutation abolished tachyphylaxis, W787A caused slowed and reduced TRPV1 desensitization. In summary, the TRPV1-ARD is crucial for desensitization, although it is unclear whether this is through a direct interaction with CaM, whereas TRPV1-CT is the major CaM interaction site but plays only a minor role in the capsaicin-induced desensitization we measured.
MATERIALS AND METHODS

Expression vectors

The C-terminal TRPV1 regions, (759-802; TRPV1-CT44 and 767-801; TRPV1-CT35) were cloned into SacI and EcoRI sites of pMALC2 (New England Biolabs), as N-terminal maltose-binding protein (MBP) fusions with a PreScission protease site (LEVLFQGP). CaM C-lobe (residues 76-148) was cloned into NdeI and BamHI sites of pET21a (Novagen). Full-length TRPV1 was expressed from pTracer-CMV2 (Lishko et al., 2007) for electrophysiology or pCDNA3-FLAG for pulldown assays. TRPV1 containing the glycosylation site mutation N604S (Rosenbaum et al., 2002) was cloned into NdeI and NotI sites of pCDNA3-FLAG. pCDNA3-FLAG was generated by ligating a short double-stranded oligonucleotide (5’-GATCACATATGGGATCCGAATTCGTCGACACTAGTGACGTCGCGGCCGCTGATTACAAGGATGACGACGATAAGTGACTCGAG-3’ and 5’-GGCCCTCGAGTCACTTATCGTCGTCATCCTTTGTAATCAGCGGCGCGACGTCGACCTAGTGTCGACGACGATAAGTGACTCGAG-3’) into the BamHI and NotI sites of pCDNA3 and mutating the NdeI site within the CMV promoter to TATATG. Cysteine mutants of CaM and TRPV1-CT were introduced using Quikchange site-directed mutagenesis (Stratagene) and confirmed by DNA sequencing.

Protein purification

Purification of CaM and TRPV1-ARD are previously described (Drum et al., 2001; Lishko et al., 2007). CaM C-lobe, CaM_{A15C} and CaM_{E127C} were purified as CaM. MBP-TRPV1-CT44 or -CT35 were expressed in BL21(DE3) induced at OD_{600} = 0.6 with 100 μM IPTG at 37°C for 2 hrs. Cells were lysed by sonication in buffer A (20 mM Tris-HCl pH 7.5, 200 mM
NaCl, 0.5 mM PMSF, 1 mM benzamidine) with 0.1% Triton-X-100, 40 μg/mL DNase, 80 μg/mL RNase, 200 μg/mL lysozyme. The cleared lysate was diluted 1:1 with buffer A supplemented with 2 mM CaCl₂, loaded onto amylose resin (NEB), washed with buffer B (20 mM Tris pH 7.5, 200 mM NaCl, 1 mM DTT and 1 mM CaCl₂) plus 0.5 mM PMSF, and eluted with buffer B plus 10 mM maltose. To obtain TRPV1-CT44/35, MBP-TRPV1-CT44/35 was concentrated and cleaved with PreScission protease overnight at 4°C. TRPV1-CT44/35 was purified on a Superdex 75 (GE Healthcare) in 20 mM Tris pH 7.5, 50 mM NaCl and 1 mM DTT, concentrated and stored at -80°C. Preparation of MBP-TRPV1-CT35 for binding assays was as above with slight modifications: (i) CaCl₂ was excluded from all buffers; (ii) 1 mM EDTA was added to lysis buffer; (iii) additional wash with buffer C (20 mM Tris pH 7.5, 25 mM NaCl, 1 mM DTT) and 1 mM PMSF before elution with buffer C and 10 mM maltose.

To obtain Ca²⁺-CaM/TRPV1-CT44/35 complex, CaM and excess TRPV1-CT44/35 (1:1.25-2.0 molar ratio) were incubated in 20 mM Tris pH 7.5, 200 mM NaCl and 0.15 mM CaCl₂. Ca²⁺-CaM/TRPV1-CT44 complex was isolated on Superdex 75 (GE Healthcare).

Structure determination

Crystals of Ca²⁺-CaM/TRPV1-CT35 (mixed at a 1.3:1 ratio at ~8 mg/mL in 20 mM Tris-HCl pH 7.5, 100 mM NaCl, 1 mM CaCl₂, 1 mM DTT) were grown by vapor diffusion at room temperature against reservoir solution (0.1 M MES pH 6.0, 2.2-2.8 M (NH₄)₂SO₄), transferred into reservoir plus 25% glycerol and flash-cooled in liquid nitrogen. Crystals of the two disulfide-crosslinked complexes were grown in very similar conditions. Diffraction data, collected at beamlines 24-ID-C and -E (Advanced Photon Source, Argonne National Laboratory) at 0.97949 Å, were processed using HKL2000 (Otwinowski and Minor, 1997). The structure was
was determined by molecular replacement using CaM coordinates of PDB entry 3DVE (Kim et al., 2008) as a search model. Model building was performed using COOT (Emsley and Cowtan, 2004) and restrained TLS refinement using REFMAC5 (Murshudov et al., 1997). The final wildtype model includes CaM residues 3-148 and TRPV1-CT35 residues 784-798 (deposited as PDB code 3SUI), with 93% of residues in most favored, 7% in allowed and none in disallowed regions of the Ramachandran plot. Data and refinement statistics are in Table I and Supplementary Table S1.

**Binding assays**

For CaM-agarose binding of MBP-tagged TRPV1-CT peptide, MBP-TRPV1-CT35 (60 μg) in 500 μL binding buffer (20 mM Tris-HCl pH 7.5, 100 mM NaCl, 0.1% TWEEN20, 1 mM DTT) supplemented with either 1 mM EGTA or 1 mM CaCl₂ was incubated with pre-equilibrated CaM-agarose (100 μL of 50% slurry; Sigma) at 4°C for 1 hr. Beads were washed thrice with 1 mL of respective binding buffers, resuspended in sample dye + 5 mM EGTA and bound protein analyzed by SDS-PAGE.

For CaM-agarose binding of FLAG-tagged TRPV1, HEK293 cells were transiently transfected with the pCDNA3-FLAG-based vectors using lipofectamine 2000 (Invitrogen). Cells were harvested in TNE buffer (10 mM Tris-HCl pH 7.5, 150 mM NaCl and 1 mM EDTA) 30-40 hr post-transfection, collected by centrifugation at 2000 x g, and lysed in 1 mL TNE buffer supplemented with 1x Complete protease inhibitor (Roche) and 1% Igepal. The detergent-soluble fraction was divided into two fractions, adding EDTA to 4 mM to one and CaCl₂ to 2 mM to the second. CaM-agarose (100 μL of 50% slurry in TNE buffer supplemented with 1x protease inhibitor and either 4 mM EDTA or 2 mM CaCl₂) was added. After a 2 hr incubation, beads
were washed five times with 1 mL of respective buffers and eluted in 80 μL of 2x SDS sample buffer supplemented with 10 mM EGTA.

**Tryptophan fluorescence**

Fluorescence experiments were performed using a Cary Eclipse fluorescence spectrophotometer at room temperature, in 10 mM Tris-HCl pH 7.5 and 100 mM KCl, with 1 mM CaCl₂ or 5 mM EDTA. Tryptophan excitation was set to 295 nm to minimize contributions of CaM tyrosines to the emission spectra. Emission spectra were recorded from 305 to 400 nm. Excitation and emission bandwidths were set at 5 nm. For intrinsic Trp fluorescence measurements of TRPV1-CT44, 10 mm pathlength cuvettes and a 1 mL volume were used to measure 10 μM TRPV1-CT44 alone or with 10 μM CaM in the presence of CaCl₂ or EDTA. For KᵋD determination, a 5 mm pathlength quartz cuvette (1 mL volume) was used. TRPV1-CT44 at 0.1 μM in 1 mL was titrated with CaM from stocks of 0.04-1 mM such that the final added volume was less than 2% of total volume. Fluorescence intensity at 330 nm was monitored and results from three replicates were analyzed using one site-specific binding nonlinear regression analysis in GraphPad Prism 5. Nonspecific binding from titrations of TRPV1-CT44 with CaM in EDTA was subtracted from total binding from same titrations in CaCl₂.

**Size exclusion chromatography (SEC) of TRPV1-ARD-CaM interactions**

SEC runs were performed as previously described (Lishko et al., 2007). Briefly, 60 μM of TRPV1-ARD and 60 μM of CaM or CaM mutants were preincubated in running buffer (20 mM HEPES pH 7.4, 140 mM NaCl, 1mM DTT and 0.16 mM CaCl₂) for 30 min on ice, followed by separation on a Superdex 75 column (GE Healthcare) at 4°C.
Disulfide-crosslinked \( \text{Ca}^{2+}\)-CaM/V1-CT35 mutants

Possible disulfide bonds between \( \text{Ca}^{2+}\)-CaM and TRPV1-CT35 were predicted (CaMA\(_{15}\)/V1-CT35\(_{N789}\) and CaM\(_{E127}\)/V1-CT35\(_{R785}\)) based on C\(\beta\)-C\(\beta\) distances using the SSBOND program (Hazes and Dijkstra, 1988). Both pairs were generated by mutagenesis, and all four resulting constructs purified as above. To test crosslinking, 20 \( \mu \)g of CaM\(_{E127C}\) or CaMA\(_{15C}\) alone or with TRPV1-CT35\(_{R785C}\) or TRPV1-CT35\(_{N789C}\), respectively, were mixed in 20 mM Tris-HCl pH 7.5, 100 mM NaCl and 1 mM CaCl\(_2\), incubated on ice for 20 min. DTT (10 mM final) or CuSO\(_4\)-1,10 phenanthroline (1-4 mM final) was added and incubated for an additional 20 min. Samples were resolved on 16% T 3% C Tricine SDS-PAGE with 4% T 3% C stacking gel as previously described (Schagger, 2006) in either reducing or non reducing sample buffers, using running buffer supplemented with 1 mM CaCl\(_2\).

For purification of CaM\(_{E127C}/\text{V1-CT35}_{R785C}\), CaM\(_{E127C}\) and TRPV1-CT35\(_{R785C}\) were mixed at 1:1.5 ratio in 20 mM Tris-HCl pH 7.5, 100 mM NaCl, 1 mM CaCl\(_2\), and CuSO\(_4\)-1,10 phenanthroline (1-4 mM) was added after 20 min, incubating 20 min further on ice. For purification of CaMA\(_{15C}/\text{V1-CT35}_{N789C}\), CaMA\(_{15C}\) and TRPV1-CT35\(_{N789C}\) were mixed at 1:2 ratio in 20 mM Tris-HCl pH 7.5, 100 mM NaCl, 2 mM CaCl\(_2\), 3 mM GSH and 0.3 mM GSSG, and incubated at room temperature overnight. Crosslinked samples were dialyzed in 20 mM Tris-HCl pH 7.5, 100 mM NaCl, 1 mM CaCl\(_2\) and purified on a Superdex 75 (GE healthcare) column.

Electrophysiology

Whole-cell patch clamping recordings were carried out in HEK293 cells transiently transfected using Lipofectamine and PLUS reagent (Invitrogen). Currents were recorded 24-36
hr post-transfection in voltage ramp experiments as previously described (Lishko et al., 2007) or in voltage clamp experiments at a holding potential of -60 mV. Standard bath solution contained 10 mM HEPES pH 7.4, 150 mM NaCl, 5 mM KCl, 2 mM CaCl₂, 1 mM MgCl₂ and 10 mM glucose. Intracellular solution contained 10 mM HEPES-CsOH pH 7.2, 140 mM Cs-methanesulfonate, 10 mM EGTA, 2.5 mM NaCl.

**Surface biotinylation assay**

Transfected HEK293 cells were rinsed twice with ice-cold PBS pH8.0 and incubated with 0.5 mg/mL sulfo-NHS-Biotin (Pierce) in PBS pH 8.0 for 30 min at 4°C. Cells were rinsed twice with cold 100 mM glycine in PBS and thrice with PBS, lysed in 1 mL of RIPA buffer (50 mM Tris-HCl pH 7.5, 150 mM NaCl, 1% NP-40, 0.5% sodium deoxycholate, 0.1% SDS, 1 mM EDTA and 1X protease inhibitor cocktail from Roche) for 1 hr at 4°C. Cleared lysates normalized for total protein concentration were incubated with 50 µL of 50% streptavidin-agarose slurry (Sigma) for 1 hr at 4°C. The beads were washed three times with RIPA buffer and eluted with 50 µL of 2x SDS sample buffer.

**Online supplemental material**

Table S1 contains data and refinement statistics for the two crosslinked Ca²⁺-CaM/TRPV1-CT35 crystal structures. Fig. S1 shows formation of the Ca²⁺-CaM/TRPV1-CT44 complex by SEC. Fig. S2 shows CaM-agarose pull-down assay results for several TRPV1-CT35 mutants. Fig. S3 shows SEC traces of experiments with rat TRPV1-ARD and CaM mutants. Fig. S4 shows SEC traces probing a possible ternary interaction between TRPV1-ARD, CaM and TRPV1-CT. Fig. S5 illustrates the crystal structures of the two crosslinked Ca²⁺-CaM/TRPV1-
CT35 complexes. Fig. S6 shows voltage-clamp experiments and cell-surface biotinylation of TRPV1 mutants expressed in HEK293 cells.
RESULTS

High-affinity interaction of TRPV1-CT with Ca\textsuperscript{2+}-CaM

A short 35-residue segment (residues 767-801) was identified as a CaM binding site in TRPV1-CT (Numazaki et al., 2003). In the same study, a longer 44-residue segment (residues 759-802) spanning this site was observed to bind CaM in the absence or presence of Ca\textsuperscript{2+} in a GST pulldown assay. We used size exclusion chromatography (SEC) to evaluate the interaction of CaM to the 44-residue segment (TRPV1-CT44) and the 35-residue segment (TRPV1-CT35; Fig. 1A). TRPV1-CT44 and -CT35 undergo a large shift in elution volume when mixed with CaM in the presence of Ca\textsuperscript{2+}, confirming that a complex is formed (Fig. 1B and Fig. S1; data shown for TRPV1-CT44).

To obtain a quantitative measurement of Ca\textsuperscript{2+}-CaM binding to TRPV1-CT, we took advantage of the intrinsic tryptophan present in TRPV1-CT peptides to monitor its binding to Ca\textsuperscript{2+}-CaM. We used TRPV1-CT44, which is more readily produced in large quantities and high purity than TRPV1-CT35. The fluorescence emission peak of tryptophan in TRPV1-CT44 is 354 nm (Fig. 1C). In the presence of CaM in CaCl\textsubscript{2} but not EDTA, the fluorescence emission peak blue-shifted to 330 nm and fluorescence intensity was enhanced, consistent with a tryptophan residue in a hydrophobic environment (Gomes et al., 2000; Weljie and Vogel, 2000). Our results further confirm that TRPV1-CT interacts with CaM in a Ca\textsuperscript{2+}-dependent manner. In a titration experiment, we measured that TRPV1-CT44 interacts with Ca\textsuperscript{2+}-CaM in a 1:1 ratio with high affinity, $K_D = 5.4 \pm 0.6 \times 10^{-8}$ M (Fig. 1D), comparable to other Ca\textsuperscript{2+}-CaM binding targets (Crivici and Ikura, 1995). Our results establish the distal TRPV1-CT region as a high affinity binding site for Ca\textsuperscript{2+}-CaM.
Overall Structure of Ca\(^{2+}\)-CaM/TRPV1-CT peptide complex

TRPV1 does not have a classical CaM recognition motif (Rhoads and Friedberg, 1997). To better understand the Ca\(^{2+}\)-CaM interaction with TRPV1-CT, we determined the crystal structure of Ca\(^{2+}\)-CaM in complex with TRPV1-CT35 (residues 767-801) to 1.95 Å resolution (Fig. 2A; Table I). The asymmetric unit contains a 1:1 Ca\(^{2+}\)-CaM/TRPV1-CT35 complex. Residues 784-798 of TRPV1-CT were observed in the structure (Fig. 2A), with the electron density is well defined for residues 785-797 (Fig. 2B-C). As expected, four Ca\(^{2+}\) ions are observed in the structure, two in each CaM lobe. TRPV1-CT35 adopts an elongated structure, with a helix (residues 787-796) flanked by two extended peptide regions (Fig. 2A). The helical peptide is clasped by both Ca\(^{2+}\)-CaM lobes in an antiparallel orientation, with its N-terminus interacting with the Ca\(^{2+}\)-CaM C-lobe and its C-terminus bound to the N-lobe. This overall Ca\(^{2+}\)-CaM/TRPV1-CT35 structure is similar to a number of canonical Ca\(^{2+}\)-CaM peptide complexes (Yamniuk and Vogel, 2004), including those of smooth muscle light chain kinase (smMLCK) (Meador et al., 1992), Ca\(^{2+}\)-CaM-dependent kinase kinase (CaMKK) (Kurokawa et al., 2001) and endothelial nitric oxide synthase (eNOS) (Aoyagi et al., 2003).

TRPV1-CT target recognition and binding by Ca\(^{2+}\)-CaM

In canonical Ca\(^{2+}\)-CaM peptide complexes, the peptide is anchored through interactions of two large hydrophobic residues to hydrophobic pockets, one on each Ca\(^{2+}\)-CaM lobe (Fig. 3A). The relative sequence position of the anchor residues defines the binding mode of Ca\(^{2+}\)-CaM/peptide complexes. TRPV1-CT35 is indeed anchored to hydrophobic pockets on the C- and N-lobes of Ca\(^{2+}\)-CaM through hydrophobic anchor residues, W787 and L796 at the C- and N-
lobe, respectively (Fig. 3B). TRPV1-CT35 therefore has a 1-10 motif like that of CaM-dependent kinase II (Meador et al., 1993).

The N-terminal anchor, W787, forms extensive hydrophobic contacts with surrounding residues F92, L105, M124 and M144 lining a deep hydrophobic pocket in the Ca$^{2+}$-CaM C-lobe (Fig. 3B). These four residues form the FLMM$_C$ tetrad, which is conserved in its interaction with its target anchor, whereas the FLMM$_N$ tetrad in the N-lobe (F19, L32, M51 and M71) is more variable (Ataman et al., 2007). The TRPV1 C-terminal anchor, L796, contacts F19, M51 and M71 from the FLMM$_N$ tetrad (Fig. 3B). In addition to the anchor residues, other hydrophobic residues along the TRPV1-CT35 $\alpha$-helix, namely F790, A791, L792, V793, P794 and L795, also form extensive hydrophobic contacts with both the N- and C-lobes of Ca$^{2+}$-CaM (Fig. 3D).

Although hydrophobic residues are major determinants of CaM interactions, basic residues mediate electrostatic contacts with the highly acidic surface of CaM and can drive the orientation of the bound CaM target (Osawa et al., 1999; Yamniuk and Vogel, 2004). Anti-parallel Ca$^{2+}$-CaM targets have positive residues near the N-terminal anchor whereas in the case of parallel Ca$^{2+}$-CaM targets, basic residues flank the C-terminal anchor (Fig. 3A). This preferential distribution of basic residues around one anchor or the other in an anti-parallel or parallel target can be understood from examining the complementary electrostatic surfaces on Ca$^{2+}$-CaM, which are important in determining the orientation of the bound peptide (Osawa et al., 1999). In our structure, basic residues R785 and K788 flank the N-terminal hydrophobic anchor W787 near the highly electronegative opening in the Ca$^{2+}$-CaM structure, while the single C-terminal basic residue, R797, is oriented toward the less electronegative opening (Fig. 4A). In summary, although no canonical CaM-binding sequence is found in the TRPV1-CT, residues
785-797 of TRPV1 interact with Ca\(^{2+}\)-CaM using hydrophobic anchors and electrostatic interactions similar to those found in well-characterized Ca\(^{2+}\)-CaM-target complexes.

**Unique features of the Ca\(^{2+}\)-CaM/TRPV1-CT35 peptide complex**

The Ca\(^{2+}\)-CaM/TRPV1-CT35 complex exhibits several unique features. The first is the structure of the TRPV1-CT peptide, which consists of a short 10-residue helix flanked by two extended peptide regions (Fig. 2A), unlike classical Ca\(^{2+}\)-CaM targets that assume longer \(\alpha\)-helical structures (Rhoads and Friedberg, 1997; Yamniuk and Vogel, 2004). Sets of available structures comprising eight parallel and 31 antiparallel Ca\(^{2+}\)-CaM/peptide structures had Ca\(^{2+}\)-CaM-interacting helices averaging 18.4 and 18.8 residues in length, respectively. Within these sets, only two other Ca\(^{2+}\)-CaM targets have short helices similar to TRPV1 – the Ca\(^{2+}\)-CaM binding domain of myristoylated alanine-rich C kinase substrate (PDB:1IWQ; MARCKS; 8-residue helix) (Yamauchi et al., 2003) and the Ca\(^{2+}\)-CaM-dependent protein kinase kinase (PDB:1CKK; CaMKK; 11-residue helix) (Osawa et al., 1999). The MARCKs and TRPV1-CT peptides share the same antiparallel orientation with respect to Ca\(^{2+}\)-CaM whereas the CaMKK peptide has a parallel orientation. The conformation of Ca\(^{2+}\)-CaM in the TRPV1-CT complex is very similar to that of the MARCKS peptide-bound Ca\(^{2+}\)-CaM (RMSD = 0.646 Å). However, in contrast to the 1-10 binding mode of TRPV1-CT35, MARCKS has no hydrophobic anchor bound to the Ca\(^{2+}\)-CaM N-lobe hydrophobic pocket. This highlights not only the conformational flexibility of Ca\(^{2+}\)-CaM to recognize its different targets but also the variability of CaM targets that can fit into the same Ca\(^{2+}\)-CaM scaffold.

A second feature unique to TRPV1-CT is that the two hydrophobic anchors are at the boundaries of the \(\alpha\)-helical region (Fig. 4B), whereas those of classical Ca\(^{2+}\)-CaM targets are
present within the α-helix. Out of the nearly 40 available Ca\(^{2+}\)-CaM/peptide complex structures that we analyzed, the only Ca\(^{2+}\)-CaM target that also carries a non-helical hydrophobic anchor is the CaMKK peptide. However, the binding modes of CaMKK and TRPV1-CT are different in all other aspects. The CaMKK peptide exhibits a parallel 1-16 binding mode, with an N-terminal tryptophan hydrophobic anchor on the α-helix and its C-terminal anchor, a phenylalanine residue, on the extended C-terminal region (Osawa et al., 1999). In summary, the structure of the Ca\(^{2+}\)-CaM/TRPV1-CT complex revealed yet another variation of Ca\(^{2+}\)-CaM target recognition motifs, with a 1-10 antiparallel binding mode in which both hydrophobic anchors bound the peptide helix.

**Both hydrophobic and positively charged residues are important determinants of binding**

Interestingly, the Ca\(^{2+}\)-CaM binding site observed in our crystal structure overlaps a previously proposed phosphatidylinositol-4,5-bisphosphate (PIP\(_2\)) binding site required for PIP\(_2\)-mediated inhibition of TRPV1 activity (Prescott and Julius, 2003), although this study’s conclusions are controversial (see Discussion). In the study, substitution of several basic residues by neutral polar residues resulted in increased sensitivity of TRPV1 to both chemical and heat stimuli. This phenotype was interpreted as a relief of inhibitory PIP\(_2\) interactions with TRPV1. In particular, the R785Q/K788Q substitution pair increased TRPV1 sensitivity to heat by shifting the temperature threshold of activation to lower temperatures. Incidentally, R785 and K788 are the two basic residues that flank the hydrophobic tryptophan anchor in our Ca\(^{2+}\)-CaM binding site (Fig. 3A). To examine whether the region observed in our structure represents bona fide determinants for Ca\(^{2+}\)-CaM binding in solution, we mutated several key residues in a MBP-fused TRPV1-CT35 and examined interactions with Ca\(^{2+}\)-CaM using a CaM-agarose pulldown assay.
Tryptophan is often found in protein interface hot spots responsible for the bulk of binding energy (Bogan and Thorn, 1998), and as anticipated, substitution of the hydrophobic anchor W787 with alanine caused a severe disruption of Ca\textsuperscript{2+}-CaM binding, underscoring the importance of the tryptophan anchor in mediating hydrophobic interactions with Ca\textsuperscript{2+}-CaM (Fig. 3C). Alanine substitutions at the R785/K788 pair also impaired Ca\textsuperscript{2+}-CaM binding, indicating that these basic residues are likewise crucial for interaction with Ca\textsuperscript{2+}-CaM (Fig. 3C), consistent with a previously published study (Grycova et al., 2008). Charge-neutralizing R785Q/K788Q substitutions, which were previously shown to potentiate TRPV1 activity (Prescott and Julius, 2003), also impair binding to Ca\textsuperscript{2+}-CaM (Fig. 3C).

A separate study aimed at identifying active or hypersensitive TRPV1 mutants using a toxicity-based screen (Myers et al., 2008) identified several mutations that fell within our Ca\textsuperscript{2+}-CaM binding site: W787R, L792P and L796P. To determine whether these mutations alter Ca\textsuperscript{2+}-CaM binding, we studied the interaction of these mutants using our CaM-agarose pulldown assay. As with W787A, W787R severely disrupted Ca\textsuperscript{2+}-CaM binding (Fig. 3C). Although mutation of the L796 C-terminal anchor to proline did not significantly disrupt binding of TRPV1-CT35 to Ca\textsuperscript{2+}-CaM in our pulldown assay (Fig. S2), the L792P substitution severely disrupted Ca\textsuperscript{2+}-CaM binding (Fig. 3C). A proline substitution at L792, which is situated in the middle of the TRPV1-CT35 helix in the Ca\textsuperscript{2+}-CaM-bound structure, would break the helical conformation of the peptide and thus likely displace other necessary Ca\textsuperscript{2+}-CaM interacting groups. In contrast, the L796P substitution is located at the C-terminal end of the helix, providing a likely explanation as to why this mutation is tolerated. Our binding assay agrees well with the observed Ca\textsuperscript{2+}-CaM/TRPV1-CT structural features.
To examine whether phosphorylation of S800, which potentiates TRPV1 (Bhave et al., 2003), interferes with Ca\(^{2+}\)-CaM binding, we mutated S800 to either an aspartic acid or glutamic acid to mimic a phosphorylation state. Neither S800D nor S800E interfered with Ca\(^{2+}\)-CaM binding (Fig. S3). This result is consistent with our structural data as S800 lies outside the region observed in our structure (Fig. 3D), and suggests that disruption of Ca\(^{2+}\)-CaM binding is not the cause of the observed phosphorylation-induced potentiation in TRPV1.

Taken together, our mutagenesis results confirmed that TRPV1-CT35 interacts extensively with Ca\(^{2+}\)-CaM through both hydrophobic and electrostatic interactions (Fig. 3D). Notably, mutation of the N-terminal tryptophan anchor alone is sufficient to severely diminish Ca\(^{2+}\)-CaM interaction, suggesting that the C-lobe of Ca\(^{2+}\)-CaM dominates the interactions with TRPV1-CT35.

**CaM C-lobe alone is sufficient to interact with TRPV1-ARD**

The interactions of Ca\(^{2+}\)-CaM with both TRPV1-ARD and TRPV1-CT are Ca\(^{2+}\)-dependent and both regions have been implicated in TRPV1 desensitization, suggesting that both sites may work in concert. One hypothesis is that Ca\(^{2+}\)-CaM bridges an interaction between the TRPV1-ARD and TRPV1-CT, leading to a closed channel (Lishko et al., 2007). CaM forms an analogous ternary complex in SK channels for example, where CaM mediates dimerization of two channel subunits through binding of its N- and C-lobe to two different subunits (Schumacher et al., 2001). Having determined that the C-lobe dominates the TRPV1-CT35 interaction, we asked whether the TRPV1-ARD is similarly dominated by a specific CaM lobe.

We have been unable to measure the affinity of TRPV1-ARD for Ca\(^{2+}\)-CaM because of technical difficulties with protein stability under various assay conditions, or to co-crystallize a
Ca²⁺-CaM/TRPV1-ARD complex to determine its structure. Instead, we tested which CaM lobe principally drives the Ca²⁺-dependent interaction with TRPV1-ARD by using SEC to compare the impact of mutations at the CaM Ca²⁺-binding sites on the interaction. CaM1, CaM2, CaM3 and CaM4 were mutated at the first (D21A), second (D57A), third (D94A) or fourth (D130A) Ca²⁺-binding sites, respectively. Rat TRPV1-ARD no longer interacted with any of the single-site CaM mutants (Fig. S3). However, rat TRPV1-ARD exhibits only a small shift by SEC when mixed with Ca²⁺-CaM, perhaps due to a weak interaction highly susceptible to perturbations. Slight differences in affinities for the distinct CaM mutants would be missed if any perturbation causes a loss of detectable binding. Therefore, we also tested interactions between the CaM mutants and chicken TRPV1-ARD, which in SEC experiments has a robust shift with wildtype Ca²⁺-CaM (Fig. 5A). Chicken TRPV1-ARD showed no interaction with CaM1234, which has all four Ca²⁺-binding sites mutated (Fig. 5B), demonstrating that the interaction with CaM is Ca²⁺-dependent. Chicken TRPV1-ARD retained the ability to interact with CaM12 but not CaM34 (Fig. 5C-D), pointing to the importance of Ca²⁺-CaM C-lobe in interacting with TRPV1-ARD. Using a truncated CaM (residues 76-148), we further showed that the isolated Ca²⁺-CaM C-lobe can bind TRPV1-ARD (Fig. 5E). While chicken and rat TRPV1-ARD may interact differently with Ca²⁺-CaM, their close homology (69.5% identity and 82.0% similarity) suggests they likely share a common binding mode (Phelps et al., 2007). Thus, our results suggest that the Ca²⁺-CaM C-lobe is crucial for binding to TRPV1-ARD.

The Ca²⁺-CaM/TRPV1-CT35 complex does not interact with TRPV1-ARD

Although the Ca²⁺-CaM C-lobe appears to dominate the interactions of both TRPV1-CT and TRPV1-ARD, it remained to be determined whether we could observe a ternary complex
between TRPV1-ARD, a TRPV1-CT peptide and Ca\(^{2+}\)-CaM. Using SEC, a shift of the rat TRPV1-ARD peak was observed in the presence of isolated Ca\(^{2+}\)-CaM/TRPV1-CT44 complex (Fig. S4). However, we could not unambiguously ascertain whether the observed TRPV1-ARD shift was due to its interaction with a Ca\(^{2+}\)-CaM/TRPV1-CT peptide complex or with Ca\(^{2+}\)-CaM alone due to overlapping elution profiles of Ca\(^{2+}\)-CaM and the Ca\(^{2+}\)-CaM/TRPV1-CT44 complex. To resolve this problem, we introduced cysteine pairs to form disulfide crosslinks between Ca\(^{2+}\)-CaM and TRPV1-CT35. Any SEC shift of TRPV1-ARD in the presence of crosslinked Ca\(^{2+}\)-CaM/TRPV1-CT35 could thereby be attributed to the binding of TRPV1-ARD to a Ca\(^{2+}\)-CaM/TRPV1-CT peptide complex.

Two cysteine pairs were engineered based on predicted optimal disulfide bond sites using SSBOND (Hazes and Dijkstra, 1988): TRPV1-CT35 N789C crosslinks to A15C in the N-lobe of Ca\(^{2+}\)-CaM, and TRPV1-CT35 R785C crosslinks to E127C in the Ca\(^{2+}\)-CaM C-lobe (Fig. 6A). Both sets of mutants display a Ca\(^{2+}\)-dependent interaction similar to wildtype Ca\(^{2+}\)-CaM and TRPV1-CT35, as shown in native gel (Fig. 6B). Although the E127C-R785C pair crosslinked more efficiently under our original conditions (Fig. 6C), we were able to isolate both crosslinked complexes with good purity (see Materials and Methods). Both crosslinked complexes crystallized under very similar conditions and in the same space group as the wildtype complex, and we determined the Ca\(^{2+}\)-CaM\(_{E127C}/\)TRPV1-CT35\(_{R785C}\) structure to 2.4 Å resolution, and the Ca\(^{2+}\)-CaM\(_{A15C}/\)TRPV1-CT35\(_{N789C}\) to 2.1 Å resolution. Both structures exhibited only minimal local conformational variations (Fig. S5). Thus the introduced crosslinks in the Ca\(^{2+}\)-CaM/TRPV1-CT peptide complex did not perturb the interactions observed in our original structure.
We then used SEC to investigate whether the crosslinked complexes interact with rat TRPV1-ARD. Neither TRPV1-ARD nor the crosslinked complexes showed a shift in elution volume when incubated together (Fig. 6D), therefore the SEC profiles showed no evidence of interaction between TRPV1-ARD and either crosslinked complex. Although we cannot rule out the possibility that crosslinking may interfere with possible conformational requirements for interaction with the TRPV1-ARD, the fact that neither Ca$^{2+}$-CaM$^{E127C}$/TRPV1-CT$^{35R785C}$ nor Ca$^{2+}$-CaM$^{A15C}$/TRPV1-CT$^{35N789C}$ interacted with TRPV1-ARD makes it unlikely that the crosslink itself prevented the interaction. Our results therefore indicate that TRPV1-ARD and TRPV1-CT do not form a ternary complex with Ca$^{2+}$-CaM under the conditions we tested.

**TRPV1-CT is the major determinant for Ca$^{2+}$-CaM binding**

Although both the isolated TRPV1-ARD and TRPV1-CT were shown to interact with Ca$^{2+}$-CaM in solution, it is unclear how these two sites contribute to Ca$^{2+}$-CaM binding in full-length TRPV1. To test this, we introduced mutations K155A or W787A, which were shown to abolish Ca$^{2+}$-CaM binding to TRPV1-ARD (Lishko et al., 2007) and TRPV1-CT (this study), respectively, and determined whether the resulting TRPV1 mutants can still bind Ca$^{2+}$-CaM using a CaM-agarose pulldown assay. Wildtype TRPV1 expressed from HEK293 cells binds CaM in a Ca$^{2+}$-dependent manner (Fig. 7A). K155A did not affect binding of TRPV1 to Ca$^{2+}$-CaM while W787A severely disrupted binding to Ca$^{2+}$-CaM, suggesting that the TRPV1-CT alone is sufficient for binding to Ca$^{2+}$-CaM. Our results support TRPV1-CT as a high affinity Ca$^{2+}$-CaM binding site in full-length TRPV1.

**Distinct roles of TRPV1-ARD and TRPV1-CT in TRPV1 desensitization**
Disruption of Ca\(^{2+}\)-CaM binding to TRPV1-ARD was shown to diminish the Ca\(^{2+}\)-dependent desensitization of TRPV1 to repeated capsaicin stimulations in whole-cell patch-clamp electrophysiology experiments (Lishko et al., 2007). To examine the functional role of the high affinity TRPV1-CT Ca\(^{2+}\)-CaM binding site, we introduced mutations that abolish Ca\(^{2+}\)-CaM binding to either TRPV1-ARD (K155A), TRPV1-CT (W787A) or both TRPV1-ARD and TRPV1-CT (K155A/W787A) and compared the capsaicin-evoked currents in HEK293 cells. We measured the maximal current amplitude evoked by each successive pulse of capsaicin using the whole-cell patch-clamp technique in voltage ramps (Fig. 8) or at a holding potential of -60 mV (Fig. S6). As expected, repeated applications of capsaicin resulted in strong tachyphylaxis of wildtype TRPV1 currents, observed as decreased inward currents (black trace, Fig. 8A). K155A showed little tachyphylaxis and slower activation kinetics as previously reported (Lishko et al., 2007). The slower activation kinetics of K155A is not due to altered surface expression (Fig. S6) and is therefore an inherent quality of the mutant. Although the slower activation kinetics could suggest a constitutively desensitized phenotype, the steady-state inward currents of K155A are larger than those of wildtype (Fig. 8C). Furthermore, it has been reported that desensitization reduces the sensitivity of TRPV1 to capsaicin (Yao and Qin, 2009), whereas we previously determined that the K155A mutant displays normal capsaicin sensitivity (Lishko et al., 2007).

In contrast, the W787A mutant showed desensitization albeit with slower kinetics and significantly higher residual currents in subsequent capsaicin application compared to wildtype TRPV1. As most tachyphylaxis occurs between the first and second application (Mohapatra et al., 2003), we compared the mean maximal current amplitude at -80 mV of the second application to that of the first application. Wildtype TRPV1-expressing cells only retained 2.3 ± 0.4 % of their maximal current at the second application, whereas W787A-expressing cells
retained 14.4 ± 3.2 % (n=8, p = 0.006). Our results with the W787A mutation are similar to those obtained when the TRPV1-CT35 region is deleted in full-length TRPV1 (Numazaki et al., 2003), showing that TRPV1-CT is indeed involved in the fast component of TRPV1 desensitization. Disruption of both Ca$^{2+}$-CaM binding sites (K155A/W787A) led to capsaicin-induced currents similar to the K155A mutation. In summary, the stronger phenotype elicited by K155A suggests a major role for TRPV1-ARD in TRPV1 desensitization, while the more subtle W787A phenotype suggests that TRPV1-CT plays a minor role in capsaicin-induced desensitization, but may be involved in other responses not discernible under our experimental conditions.
**DISCUSSION**

In this study, we present the structure of Ca\(^{2+}\)-CaM bound to a short 35-residue TRPV1 C-terminal region (TRPV1-CT35), one of two identified Ca\(^{2+}\)-CaM binding sites in TRPV1. The second Ca\(^{2+}\)-CaM binding site was previously identified in TRPV1-ARD (Rosenbaum et al., 2004), where Ca\(^{2+}\)-CaM competes with a TRPV1 sensitizer, ATP, for binding (Lishko et al., 2007). Our affinity measurements indicate that TRPV1-CT represents a high affinity binding site for Ca\(^{2+}\)-CaM (K\(_D\) = 5.4 ± 0.6 x 10\(^{-8}\) M). Although we could not measure the affinity of TRPV1-ARD for Ca\(^{2+}\)-CaM because of technical difficulties, our SEC experiments suggest that the affinity is likely significantly lower than that of the TRPV1-CT. Consistently, a mutation that abolished Ca\(^{2+}\)-CaM binding to TRPV1-CT (W787A), but not a corresponding one in TRPV1-ARD (K155A), severely disrupted binding to Ca\(^{2+}\)-CaM in full-length TRPV1. The W787A mutation was sufficient to slow and reduce TRPV1 desensitization, consistent with a 35-amino acid deletion mutant that also exhibited reduced Ca\(^{2+}\)-dependent desensitization of TRPV1 (Numazaki et al., 2003).

The interaction of Ca\(^{2+}\)-CaM with TRPV1-CT35 is similar to that observed in canonical Ca\(^{2+}\)-CaM/target complexes. The bound peptide adopts an α-helical conformation and binds Ca\(^{2+}\)-CaM in an anti-parallel manner through two hydrophobic anchors, W787 and K796, corresponding to a 1-10 binding motif. Sequence alignment of the TRPV1 C-terminal CaM-binding site identified in the rat TRPV1 sequence with TRPV1 from other species shows that this site is conserved (Fig. 7B), suggesting a conserved function.

The TRPV1-CT Ca\(^{2+}\)-CaM binding site identified in our structure overlaps a region previously identified as an inhibitory PIP\(_2\) binding domain, although no direct binding was demonstrated (Prescott and Julius, 2003). A subsequent study found that the inhibitory effects of
PIP₂ on TRPV1 were only detectable in whole cells, not excised patches, suggesting that PIP₂-mediated inhibition is indirect (Lukacs et al., 2007). Furthermore, PIP₂ can also potentiate TRPV1 (Liu et al., 2005; Lishko et al., 2007; Lukacs et al., 2007), and does so through a proximal C-terminal region (residues 682 to 725) (Ufret-Vincenty et al., 2011). Together with these findings on TRPV1 regulation by PIP₂, our data support the distal C-terminal region of TRPV1 as a physiologically important Ca²⁺-CaM binding site.

The interactions of Ca²⁺-CaM with both TRPV1-ARD and TRPV1-CT are implicated in TRPV1 desensitization (Numazaki et al., 2003; Lishko et al., 2007). This brings up the question of whether Ca²⁺-CaM regulation of TRPV1 at TRPV1-ARD and TRPV1-CT constitutes integrated or separate mechanisms. Several findings suggested that both sites may work together in the desensitization mechanism. First, mutations or deletion of the Ca²⁺-CaM-binding site either in TRPV1-ARD or TRPV1-CT disrupts desensitization (Numazaki et al., 2003; Lishko et al., 2007). Second, a toxicity-based screen for active or hypersensitive TRPV1 phenotype (Myers et al., 2008) identified mutations that impair Ca²⁺-CaM binding in either TRPV1-ARD, such as K155E/A and K160E/A (Lishko et al., 2007), or TRPV1-CT, such as W787R and L792P (Fig. 3C). One hypothesis is that Ca²⁺-CaM may bridge an interaction between TRPV1-ARD and TRPV1-CT (Lishko et al., 2007). A similar mechanism is postulated for CaM regulation of voltage-gated Ca,1 channels (Dick et al., 2008), and CaM bridges two subunits of a Ca²⁺-activated K⁺ channel (Schumacher et al., 2001). Here we generated two different crosslinked Ca²⁺-CaM/TRPV1-CT complexes, but did not observe any ternary assemblies of these crosslinked complexes with TRPV1-ARD. This suggests that the Ca²⁺-CaM-mediated desensitization of TRPV1 may instead involve separate pathways. However, we cannot rule out the possibility that the introduced crosslinks, which maintain the interactions observed in the
uncrosslinked complex (Fig. S5), may restrict conformational changes required for interaction with TRPV1-ARD.

We observed a more pronounced disruption of desensitization in response to capsaicin when mutating the N-terminal K155A than the C-terminal W787A, suggesting that the TRPV1-ARD is most important for tachyphylaxis. Mutation of the C-terminal site, on the other hand, led to a more subtle phenotype of slowed and reduced desensitization (Fig. 8). Notably, the C-terminal site was most important for Ca\(^{2+}\)-CaM binding in our pulldown assays. Therefore, our data suggest that Ca\(^{2+}\)-CaM binding may not be the dominant regulatory factor for TRPV1 desensitization. Overall, our data are consistent with a model where PIP\(_2\) depletion is a major contributor to the acute desensitization of TRPV1 after activation by capsaicin (Lukacs et al., 2007; Mercado et al., 2010), with Ca\(^{2+}\)-CaM binding to the TRPV1-CT likely playing a supporting role.

It is possible that the C-terminal Ca\(^{2+}\)-CaM binding site plays a more important role in regulating other TRPV1 responses not tested in the current study. Several studies hint at a role of the TRPV1-CT Ca\(^{2+}\)-CaM binding site in tuning channel sensitivity. Increased sensitivity to heat and/or hypersensitivity was observed in several C-terminal mutants (Prescott and Julius, 2003; Myers et al., 2008) and in the vampire bat TRPV1-S isoform in which the C-terminal binding site is absent (Gracheva et al., 2011).

In summary, we showed that TRPV1-CT represents a high affinity binding site for Ca\(^{2+}\)-CaM. The TRPV1-ARD and TRPV1-CT likely provide two separate regulatory pathways, a model that is supported by both our biochemical and electrophysiological analyses. Our work provides new biochemical and structural information that enables future studies to fully decipher the molecular mechanisms behind the physiological regulation of TRPV1 responses.
ACKNOWLEDGMENTS

We thank current and former lab members for technical help and discussions. Special thanks to Wilhelm Weihofen for advice and assistance on x-ray crystallography, Marcos Sotomayor and Ahmet Vakkasoglu for x-ray data collection, Alejandra Beristain-Barajas for technical assistance, and Hitoshi Inada for assistance with electrophysiology and discussions and insights to this work. We are grateful to Narayanasami Sukumar and staff at the Northeastern Collaborative Access Team (NE-CAT), beamline 24-ID-C, for assistance with data collection. This work was supported by NIH (R01GM081340) and Klingenstein Awards to R.G. Use of APS beamlines was supported by NIH award RR-15301 and DOE contract DE-AC02-06CH11357.

FIGURE LEGENDS

Figure 1. TRPV1 C-terminal CaM binding site. (A) Schematic diagram showing the domain organization of TRPV1. CaM and putative CaM binding sites are shaded in light grey. (B) SEC elution profile of TRPV1-CT44 alone or in complex with Ca\textsuperscript{2+}-CaM. Shown are representative traces of a TRPV1-CT44 preparation (grey) following cleavage of a MBP tag (*) and Ca\textsuperscript{2+}-CaM/TRPV1-CT44 complex (black). (C) Tryptophan fluorescence emission spectra of 10 μM of TRPV1-CT44 (residues 759-802) alone or incubated with equimolar amounts of CaM in the presence of CaCl\textsubscript{2} or EDTA, excited at 295 nm. (D) Titration of TRPV1-CT44 (0.1 μM) with CaM from 0.01-1 μM in the presence of CaCl\textsubscript{2}. Tryptophan fluorescence emission at 330 nm was plotted against CaM concentration. Data were obtained in triplicate and analyzed using one site-specific binding nonlinear regression analysis in GraphPad Prism 5. Line shows the best fit to the data, $K_D = 5.4 \pm 0.6 \times 10^{-8}$ M.

Figure 2. Structure of a TRPV1 C-terminal peptide in complex with Ca\textsuperscript{2+}-CaM. (A) Ribbon diagrams of TRPV1-CT35 (cyan) bound to Ca\textsuperscript{2+}-CaM, shown in two different orientations; the view on right is rotated 70° around the vertical axis with respect to the one on the left. The CaM N- and C-lobes are yellow and orange, respectively, and the calcium ions are grey. (B) Stereoview of TRPV1-CT35 (stick representation; residues 785-797) bound to Ca\textsuperscript{2+}-CaM (grey ribbons with dark grey Ca\textsuperscript{2+} ion spheres). The 2F\textsubscript{o}-F\textsubscript{c} electron density map corresponding to TRPV1-CT35 is shown in cyan, contoured at 1.0 σ. (C) Stereoview of TRPV1-CT35 in stick representation with the corresponding 2F\textsubscript{o}-F\textsubscript{c} electron density map contoured at 1.0 σ (cyan). Several key residues are labeled.
**Figure 3.** The Ca$^{2+}$-CaM/TRPV1-CT interface. (A) Aligned sequences of Ca$^{2+}$-CaM binding peptides with anti-parallel 1-10 motifs (TRPV1-CT, CaMKIIa (Meador et al., 1993)) and 1-14 motifs (smMLCK (Meador et al., 1992), skMLCK (Ikura et al., 1992), CaMKI (Clapperton et al., 2002)), and parallel 1-16 motifs (CaMKK$\alpha$ (Osawa et al., 1999) and cCAMKKp (Kurokawa et al., 2001)). Residues are colored as follows: positively charged, blue; negatively charged, red; and hydrophobic, orange. Hydrophobic anchors are boxed in black. (B) Lobe-specific interactions, featuring hydrophobic pockets on CaM, with the CaM C- and N-lobes shown in surface representation. The views of the C- and N-lobes are related to Figure 2A by rotations of $+80^\circ$ and $-100^\circ$ around the horizontal axis, respectively. CaM residues that contact TRPV1-CT35 (interatomic distances $\leq 4.2$ Å) are colored according to their side chain properties (hydrophobic, orange; positively charged, blue; negatively charged, red; polar, green) and selected ones are labeled in black. Selected TRPV1 residues are labeled in cyan. (C) CaM-agarose pulldowns of maltose-binding-protein (MBP)-fused TRPV1-CT35 peptides (residues 767-801). A Coomassie-stained gel of pulldowns in the absence (EGTA) or presence (Ca$^{2+}$) of calcium is shown as a representative result of three independent experiments. An MBP-$\alpha$-Gal protein construct, expressed from the unmodified vector, was used as a negative control. (D) Sequence map of CaM residues in contact with TRPV1-CT35 (interatomic distances $\leq 4.2$ Å). CaM N-lobe, C-lobe and TRPV1-CT35 residues are mustard, orange and cyan respectively. Interacting CaM residues making at least one polar contact are boxed.

**Figure 4.** Electrostatic surface potential of Ca$^{2+}$-CaM and TRPV1-CT peptide. Surface of Ca$^{2+}$-CaM (top) viewed from N- (left) and C-terminal (right) face of equivalently positioned TRPV1-
CT peptide (bottom). The molecular surface is colored according to the electrostatic potential from red (-6 kT/e) to blue (6 kT/e). Electrostatic potential surfaces were generated in PyMOL using APBS (Baker et al., 2001). (B) Cartoon representation of TRPV1-CT peptide against surface representation of binding pocket, showing the hydrophobic anchors: W787 (left) and L796 (right) positioned at the TRPV1-CT helix N- and C-termini, respectively.

**Figure 5.** The C-lobe of Ca\(^{2+}\)-CaM is necessary and sufficient to interact with chicken TRPV1-ARD. (A-E) SEC elution profiles of chicken (*Gallus gallus*) TRPV1-ARD (GgV1ARD) mixed with various CaM mutants. A physical interaction was observed in the presence of 2 mM Ca\(^{2+}\) for wildtype CaM, CaM12 and CaM C-lobe, as indicated by a left-shift of the peak for the mixed proteins (60 µM GgV1ARD and 60 µM CaM; black) compared to elution volumes of the individual proteins (GgV1ARD, grey; CaM, dashed black). Shown are representative traces from two repeats. Wildtype CaM was used in (A), followed by CaM mutated at all four Ca\(^{2+}\) sites (B, CaM1234), the two N-lobe Ca\(^{2+}\) sites (C, CaM12) or the two C-lobe Ca\(^{2+}\) sites (D, CaM34). (E) The isolated C-lobe of CaM (residues 76-148) interacts with chicken TRPV1-ARD by SEC. (F) Coomassie-stained gels from SEC runs in (E). The lanes from left to right are fractions of increasing elution volume, from 10.5 to 15.5 mL.

**Figure 6.** Disulfide-crosslinked Ca\(^{2+}\)-CaM/TRPV1-CT35 complexes do not interact with TRPV1-ARD. (A) Ribbon diagram of TRPV1-CT35 (cyan) bound to Ca\(^{2+}\)-CaM (grey) with modeled disulfide bonds (pink) based on predictions using SSBOND (Hazes and Dijkstra, 1988). (B) Native-PAGE of CaM or CaM cysteine mutants alone or in the presence of increasing molar ratio of respective TRPV1-CT or TRPV1-CT mutant. (C) Tricine-SDS-PAGE of CaM and
TRPV1-CT35 cysteine mutants under reducing or oxidizing conditions. (D) Purified rat TRPV1-ARD (RnARD; 60 μM) was mixed with CaM (60 μM; left), the crosslinked complex CaM_{E127C/V1-CT35R785C} (60 μM; middle) or CaM_{A15C/V1-CT35N789C} (60 μM; right) in the presence of CaCl_2 and separated using SEC.

**Figure 7.** The conserved TRPV1-CT sequence is necessary for interaction of full-length TRPV1 with Ca\textsuperscript{2+}-CaM. (A) Tryptophan 787 is necessary for the interaction of full-length TRPV1 with Ca\textsuperscript{2+}-CaM. Detergent-soluble fractions of HEK293 cells expressing wildtype, K155A or W787A FLAG-tagged TRPV1 were incubated with CaM-agarose beads in the presence of EDTA or CaCl_2, washed and the bound fractions were eluted and analyzed by western blot using anti-FLAG antibody. Shown is a representative result of three independent experiments. (B) Sequence alignment of the rat TRPV1-CT35 region with representative mammalian and avian species shows that the region is highly conserved (sequence identity over the whole protein sequence of rat TRPV1 vs. mouse, human, guinea pig, bovine, rabbit, chicken, and bat splice variants (long and short) TRPV1 is 96%, 86%, 89%, 86%, 87%, 67% 86% and 87% respectively). Non-conserved residues are shaded grey. The region visible in the crystal structure (residues 784-798) and the helical region (788-796) are indicated above the alignment (cyan).

**Figure 8.** Mutations that reduce CaM binding to the TRPV1-ARD or TRPV1-CT caused different defects in TRPV1 current desensitization in HEK293 cells. (A) Representative traces of capsaicin-evoked whole-cell currents in response to repeated capsaicin applications in the presence of extracellular Ca\textsuperscript{2+}. Cells were repeatedly stimulated with 1 μM capsaicin for 1 min
followed by 1 min washouts. The +80 mV (red) and -80 mV (black) currents extracted from 1500 ms voltage ramps are shown. (B) Mean current amplitudes for successive capsaicin applications were normalized to the maximal current amplitudes of the first capsaicin application. * indicates p < 0.01 vs. TRPV1 WT using two-tailed unpaired t tests. (C) Mean current density of the maximal response to the first capsaicin application normalized to the cell capacitance. The values in (B) and (C) were calculated from current amplitudes at -80 mV (negative scale) and +80 mV (positive scale) measured in experiments as in (A). Bars represent mean ± SEM (n = 6, 8, 8, 8 for WT, W787A, K155A and W787A/K155A, respectively).

Figure S1. Size exclusion chromatography (SEC) elution profile of TRPV1-CT44 alone or in complex with Ca^{2+}-CaM as shown in Figure 1D. Shown are representative traces of a TRPV1-CT44 preparation (grey) following cleavage of a MBP tag (*) and Ca^{2+}-CaM/TRPV1-CT44 complex (black) (see Materials and Methods). Silver-stained gels of eluted fractions from TRPV1-CT44 and Ca^{2+}-CaM/TRPV1-CT44 are shown above and below, respectively.
Figure S2. Phosphomimetic mutations of S800 and mutation of the CaM N-lobe anchor do not interfere with Ca\textsuperscript{2+}-CaM binding to TRPV1-CT. CaM-agarose pulldowns of maltose-binding-protein (MBP)-fused TRPV1-CT35 peptides (residues 767-801). S800D/E substitutions were made to mimic the phosphorylated state. Coomassie-stained gel of pulldowns in the absence (EGTA) or presence (Ca\textsuperscript{2+}) of calcium is shown as a representative result of three independent experiments. An MBP-\alpha-Gal protein construct, expressed from the unmodified vector, was used as a negative control.
Figure S3. The rat TRPV1-ARD interaction with Ca\(^{2+}\)-CaM requires all four calcium binding sites. Purified rat TRPV1-ARD (RnV1ARD; 60 µM) was mixed with CaM (CaM; 60 µM) in the presence of 2 mM Ca\(^{2+}\) and separated by SEC. A physical interaction was observed only for wildtype CaM, as indicated by a shift of the peak of the mixed proteins (orange) to the left compared to elution volumes of the individual proteins (RnV1ARD, grey; CaM, black). Shown are representative traces from two repeats. CaM mutated at each of four Ca\(^{2+}\) sites (CaM1, CaM2, CaM3 or CaM4), the two N-lobe Ca\(^{2+}\) sites (CaM12), the two C-lobe Ca\(^{2+}\) sites (CaM34) or all four sites (CaM1234) did not show evidence of interaction with rat TRPV1-ARD, as evidenced by the lack of a significant shift in elution volume.
Figure S4. Chicken TRPV1-ARD (GgV1ARD) shifts to higher MW fractions by SEC when mixed with preformed Ca\textsuperscript{2+}-CaM/TRPV1-CT44 complex. (A) SEC elution profiles of Ca\textsuperscript{2+}-CaM/TRPV1-CT44 (dashed line) GgV1ARD (grey) alone or when mixed together (black). Purified GgV1ARD (60 µM) was mixed with Ca\textsuperscript{2+}-CaM/TRPV1-CT44 complex (60 µM) in the presence of 0.15 mM Ca\textsuperscript{2+} and separated by SEC. Shown are representative traces from two repeats. (B) Silver-stained gels from SEC runs in (A). The lanes from left to right are fractions of increasing elution volume, from 10 to 14 ml.
Figure S5. The structures of crosslinked complexes are very similar to the wildtype complex. (A, B) 2F₀-Fₑ electron density maps corresponding to the region of the Ca²⁺-CaME₁₂₇C/TRPV₁-CT₃₅R₇₈₅C disulfide (A) and Ca²⁺-CaMA₁₅C/TRPV₁-CT₃₅N₇₈₉C (B), contoured at 1.0 σ in magenta (blue CaM and green V1-CT peptide). Note that both the CaME₁₂₇C/TRPV₁-CT₃₅R₇₈₅C and Ca²⁺-CaMA₁₅C/TRPV₁-CT₃₅N₇₈₉C peptide N-termini are poorly ordered, similar to the wildtype structure, indicating that the disulfides do not constrain the structures. (C, D) The structures of the crosslinked complexes (blue CaM and green V1-CT peptide), Ca²⁺-CaME₁₂₇C/TRPV₁-CT₃₅R₇₈₅C (C) and CaME₁₂₇C/TRPV₁-CT₃₅R₇₈₅C (D), are superimposed with wildtype Ca²⁺-CaM/TRPV₁-CT₃₅ (grey CaM and cyan V1-CT peptide). Both crosslinked structures show few differences when compared to wildtype. The RMSD to the wildtype structure are:

(C) 0.580 Å for all 161 common Cα atoms and 0.206 Å for the best fitting 146 Cα atoms for CaME₁₂₇C/TRPV₁-CT₃₅R₇₈₅C;
(D) 0.290 Å for all 158 common Cα atoms and 0.193 Å for the best fitting 141 Cα atoms for Ca²⁺-CaMA₁₅C/TRPV₁-CT₃₅N₇₈₉C.
Figure S6. Mutations that reduce CaM binding to the TRPV1-ARD or TRPV1-CT caused different defects in TRPV1 current desensitization in HEK293 cells. (A) Representative traces of capsaicin-evoked whole-cell currents in the presence of extracellular Ca²⁺. Cells were held at -60 mV and repeatedly stimulated with 1 μM capsaicin for 1 min followed by 1 min washouts. (B) Cell-surface expression of TRPV1. Cell-surface proteins were biotinylated, pulled down with streptavidin-agarose beads and immunoblotted with anti-TRPV1 antibody (see Materials and Methods). Shown is a representative result of three independent experiments. Upper and lower bands likely correspond to N-glycosylated and non-glycosylated forms of TRPV1, respectively (Rosenbaum et al., 2002).
