ABSTRACT: A one-step oxidative fluorination for carbon–fluorine bond formation from well-defined nickel complexes with oxidant and aqueous fluoride is presented, which enables a straightforward and practical 18F late-stage fluorination of complex small molecules with potential for PET imaging.

Positron emission tomography (PET) requires synthesis of molecules that contain positron-emitting isotopes, such as 11C, 13N, 15O, and 18F.1 The 18F isotope is typically the preferred radionuclide for clinically relevant PET applications due to its longer half-life of 110 minutes, which permits synthesis and distribution of radiotracer quantities appropriate for imaging.2 But C–F bond formation is challenging, especially with 18F.3 Here we report a practical late-stage fluorination reaction with high-specific activity 18F fluoride to make aryl and alkenyl fluorides from organometallic nickel complexes. A direct oxidative fluorination of organotransition metal complexes with oxidant and fluoride has never been reported, and enables practical one-step access to complex 18F-labeled small molecules from [18F]fluoride. When nickel complexes 1 are combined with oxidant and aqueous fluoride, the organic fluorides 2 are formed at room temperature in less than a minute (eq 1).

(1)

Synthesis of simple 18F PET tracers is typically accomplished with conventional nucleophilic substitution reactions with [18F]fluoride.1,4 [18F]Fluoride is the only readily available source of F-18. But conventional nucleophilic substitution reactions commonly only give access to simple molecules, and have a small substrate scope. C–F bond formation is more difficult with 18F than with the naturally occurring 19F, and most modern, functional group-tolerant fluorination reactions are not currently useful for applications in PET.5 In addition to the challenges associated with 19F fluorination,3 chemistry with 18F needs to take into account the small concentration of 18F (roughly 10^{-4} M), the impracticality to work under rigorously anhydrous conditions, and the side product profile. We sought to develop a practical, one-step, functional group tolerant, electrophilic fluorination reaction that employs [18F] fluoride.

We had previously developed the electrophilic fluorination reagent 4 made from high-specific activity [18F]fluoride via reductive elimination from high-valent palladium fluoride complexes (Scheme 1).6 Palladium complex 4 can be used for late-stage 18F fluorination of complex arenes and was the first reagent to capture fluoride and subsequently function as electrophilic fluorination reagent. Yet, use of 4 requires a two-step sequence: fluoride capture (3 → 4), followed by fluoride transfer via electrophilic fluorination (5 → [18F]2). The 2-step sequence increases reaction time and possibility for error, and makes the method less suitable for adoption by non-chemists. Moreover, the fluoride must be dried azeotropically, as is common for most reactions that use [18F]fluoride.1

Scheme 1. Two-Step Late-Stage Fluorination via Pd(IV) Fluoride Complex 4.
This manuscript reports on fluorination of arylnickel complexes that avoid some of the limitations inherent to the palladium chemistry shown in scheme 1, most notably the two-step procedure. We established the relevance of nickel aryl complexes 1 to the direct oxidative fluorination with fluoride through reaction of 1a with hypervalent iodine oxidant 6 and tetrabutylammonium difluorotriphenylsilicate (TBAT) as fluoride source, which afforded 65% isolated yield of aryl fluoride 2a after chromatographic purification on silica gel (eq 2).

For radiofluorination, a solution of aqueous [18F]fluoride (2–5 μl, 100–500 μCi) containing 2 mg of 18-cr-6 in MeCN (200-500 μl) was added to a mixture of 1.0 mg of nickel complex 1 and 1.0 equivalents (relative to 1) of oxidant 6 at room temperature under ambient atmosphere in a vial. After less than one minute after addition, the fluorination reactions were analyzed by radioTLC and HPLC for radiochemical yield and product identity, respectively (Table 1). All reactions proceeded without deliberate addition of [18F]fluoride (no-carrier-added). No carrier-added 18F fluorination allows for the synthesis of 18F-labeled molecules of high specific activity. For example, compound 2g was prepared in 1.1 Ci·µmol⁻¹. The transformation is successful for the synthesis of electron-rich, electron-poor, ortho-, meta-, and para-substituted, and densely functionalized aryl fluorides, as well as for alkenyl fluorides. Tertiary amines are currently not tolerated, presumably due to unproductive reaction of oxidant 6 with nucleophiles such as amines.

The ability to use aqueous fluoride solutions makes extensive drying procedures, that are typical for radiochemistry with [18F]fluoride, superfluous. Drying procedures increase the time from [18F] production to tracer purification; for example, drying fluoride for the reaction shown in scheme 1 takes longer than the 20-minute reaction time. The direct use of aqueous fluoride solution presented here avoids unproductive radioactive decay, and also increases the yield based on fluoride because dying commonly results in significant fluorine content absorbed onto walls of glass reaction vessels. The aqueous fluoride solution can be used without ion exchange that is normally required for radiochemistry with [18F]fluoride, which further increases practicality and reduces reaction time. To facilitate purification subsequent to fluorination, it is desirable to employ as little starting material (e.g. 1) as possible for radiofluorination, and 1 mg of nickel complex (ca. 1 µmol) is a low amount compared to other [18F] radiofluorination reactions. For example, the method presented here requires an order of magnitude less starting material than the palladium-mediated method described in Scheme 1, and still affords generally higher radiochemical yields.

Table 1. Fluorination of Ni(II)-Aryl Complexes with [18F] Fluoride
The one-step oxidative fluorination of well-defined nickel complexes with oxidant and aqueous fluoride enables a straightforward and practical $^{18}$F late-stage fluorination of complex small molecules. Operational simplicity of the fluorination, most notably the ability to use aqueous solutions of $^{[18]}$Ffluoride, will also empower non-experts to obtain previously unavailable $^{18}$F-labeled molecules, and showcases the potential of modern organometallic chemistry for applications in PET. The transformation represents the first example of fluorination with a first row transition metal organometallic, and the first example of a reaction that affords aryl fluoride by $^{19}$F$^-$C bond formation at room temperature within seconds using an aqueous solution of $^{18}$F fluoride. Going forward, we will evaluate the possibility of translating the transformation to automated radiosyntheses as well as PET imaging applications.
