Abstract—High performance InGaAs gate-all-around (GAA) nanowire MOSFETs with channel length \( L_{\text{ch}} \) down to 20nm have been fabricated by integrating a higher-\( k \) LaAlO\(_3\)-based gate stack with an equivalent oxide thickness of 1.2nm. It is found that inserting an ultrathin (0.5nm) Al\(_2\)O\(_3\) interfacial layer between higher-\( k \) and InGaAs can significantly improve the interface quality and reduce device variation. As a result, a record low subthreshold swing of 63mV/dec has been demonstrated at sub-80nm \( L_{\text{ch}} \), for the first time, making InGaAs GAA nanowire devices a strong candidate for future low-power transistors.

Index Terms—Variability, MOSFET, InGaAs, nanowire.

I. INTRODUCTION

II-V compound semiconductors have recently been explored as alternative channel materials for future CMOS technologies [1]. In\(_3\)Ga\(_{1-x}\)As gate-all-around (GAA) nanowire MOSFETs fabricated using either bottom-up [2], [3] or top-down technology [4]–[6] are of particular interest due to their excellent electrostatic control. Although the improvement of on-state and off-state device metrics has been enabled by nanowire width \( W_{\text{NW}} \) scaling, the scalability of the devices in [4] is greatly limited by the large equivalent oxide thickness \( EOT \) of 4.5nm. Aggressive \( EOT \) scaling is required to meet the stringent requirements on electrostatic control [5], [7], [8]. It is shown recently that sub-1nm \( EOT \) with good interface quality can be achieved by Al\(_2\)O\(_3\) passivation on planar InGaAs devices [9]. Considering the inherent 3D nature of the nanowire structure, whether such a gate stack technology can be successfully integrated in the InGaAs nanowire MOSFET fabrication process remains to be shown. In addition, the electron transport in the devices [4] can be enhanced by increasing the Indium concentration in the InGaAs nanowire channel, which promises further on-state metrics improvements such as on-current \( I_{\text{ON}} \) and transconductance \( g_m \).

In this letter, we fabricated In\(_{0.65}\)Ga\(_{0.35}\)As GAA nanowire MOSFETs with atomic layer deposited (ALD) LaAlO\(_3\)-based gate stack \( EOT=1.2nm \). ALD LaAlO\(_3\) is a promising gate dielectric for future 3D transistors because of its high dielectric constant \( k=16 \), precise thickness control, excellent uniformity and conformality [10]. The effect of ultra-thin Al\(_2\)O\(_3\) insertion on the device on-state and off-state characteristics has been systematically studied. It is shown that Al\(_2\)O\(_3\) insertion effectively passivates the LaAlO\(_3\)/InGaAs interface, leading to the improvement in both device scalability and variability. Record low subthreshold swing \( SS \) of 63mV/dec has been achieved at sub-80nm \( L_{\text{ch}} \), indicating excellent interface quality and gate electrostatic control. Detailed device variation analysis has been presented for the first time for InGaAs MOSFETs, which helps identify new manufacturing challenges for future logic devices with high mobility channels.

II. EXPERIMENT

Fig. 1(a) and (b) show the schematic diagram and cross sectional view of InGaAs GAA nanowire MOSFETs with ALD Al\(_2\)O\(_3\)/LaAlO\(_3\) gate stack. (c) Output characteristics (source current) of InGaAs GAA nanowire MOSFETs \( L_{\text{ch}}=20nm \) with Al\(_2\)O\(_3\)-first (solid line) and LaAlO\(_3\)-first (dashed line) gate stack.

4nm LaAlO₃, and 40nm WN high-k/metal gate stack were grown by ALD surrounding all facets of the nanowires. Two samples were fabricated in parallel with only the sequence of the Al₂O₃ and LaAlO₃ growth deliberately switched. Both samples were treated with 10% (NH₄)₂S, and then transferred into the ALD chamber within 1 minute of air break. Since the Al₂O₃-first and LaAlO₃-first sample had the same EOT of 1.2nm and underwent the same process flow, the difference of device performance can be ascribed to the effect of the Al₂O₃ passivation. All other fabrication details can be found in [4]. In this letter, the channel length (L₉₀) is defined as the width of the electron beam resist in the source/drain implantation process and has been verified by scanning electron microscopy.

III. RESULTS AND DISCUSSION

![Fig. 2.](image)

(a) Transfer characteristics (source current) at Vds=0.05, 0.5, and 1V. (b) gm-Vgs of Al₂O₃-first and LaAlO₃-first InGaAs GAA nanowire MOSFETs with Lch = 20nm.

Fig. 1(c) shows the output characteristics of two representative Al₂O₃-first and LaAlO₃-first InGaAs GAA nanowire MOSFETs with Lch = 20nm. Fig. 2(a) and (b) show the transfer characteristics and transconductance of the same devices. Due to the large junction leakage current in the drain, the source current Ig is shown in the current-voltage characteristics and used to calculate ION and gₘ. The Al₂O₃-first device shows higher ION = 57μA/wire at VDD = VDS = Vgs – VT = 0.5V and peak transconductance gₘ,max = 165μS/wire at VDS = 0.5V, compared to 48μA/wire and 155μS/wire for the LaAlO₃-first device. Both devices operate in enhancement-mode, with a linearly extrapolated VTH of 0.14V and 0.11V, respectively. For the off-state performance, the Al₂O₃-first device shows a SS of 75mV/dec and DIBL of 40mV, while the LaAlO₃-first device shows higher SS of 80mV/V and higher DIBL of 73mV/V. To study the statistical distribution of the on-state metrics, the box plots for ION and gₘ,max at VDD = 0.5V are shown in Fig. 3. The box plots include measurements from all 50 devices with Lch of 20nm and WNW of 20nm. Although only a 12% (10%) increase in mean ION (gₘ,max) is observed for the devices with Al₂O₃ insertion, a 54% (64%) reduction in standard deviation of ION (gₘ,max) is obtained on the Al₂O₃-first devices, indicating a significant improvement in device variation by effective passivation of interface traps. The ION variation is impacted by several variation sources including parasitic resistance, effective mobility and VTH variation [11], all of which are sensitive to the interface quality of the high-k/InGaAs nanowire surface.

To further investigate the scalability and off-state performance variability, the averages and standard deviations of SS, DIBL and VTH as a function of Lch are shown in Fig. 4 for Al₂O₃-first and LaAlO₃-first devices with WNW = 20nm. The SS and DIBL remain almost constant with Lch scaling down to 50nm for both samples. This indicates that the current GAA structure with 1.2nm EOT has yielded a very small geometric screening length and the devices show excellent resistance to short channel effects. Average SS = 76mV/dec and DIBL = 25mV/V are obtained for Al₂O₃-first devices with Lch between 50 and 80nm, compared to 79mV/dec and 39mV/V for the LaAlO₃-first devices, indicating a reduction of interface trap density (Dit) with Al₂O₃ passivation. A small increase in VTH is also observed for the Al₂O₃-first sample, which is ascribed to the reduction in negative donor-type charges at the interface. Furthermore, larger standard devia-
low interface quality of the LaAlO$_3$-first devices introduced additional device variation. It is also shown that the off-state performance variation increases as $L_{ch}$ scales below 50nm, which is ascribed to the reduction in electrostatic control.

![Fig. 5](image)

Fig. 5. (a) $SS$ box plot and histogram for all Al$_2$O$_3$-first and LaAlO$_3$-first devices with $L_{ch}$ between 50–80nm and $W_{NW}$ of 20nm. (b) Transfer characteristic (source current) of a Al$_2$O$_3$-first and a LaAlO$_3$-first InGaAs GAA nanowire MOSFET with lowest $SS$ of 63mV/dec and 69mV/dec, respectively.

Fig. 5(a) show the box plot and histogram of $SS$ measured from all the Al$_2$O$_3$-first and LaAlO$_3$-first devices with $L_{ch}$ between 50–80nm and $W_{NW}$ of 20nm. Although the average $SS$ for Al$_2$O$_3$-first devices is only 1.9mV/dec lower than LaAlO$_3$-first devices, 25% and 46% reduction in standard deviation and interquartile range has been obtained on Al$_2$O$_3$-first devices, indicating the effectiveness of Al$_2$O$_3$ passivation. Since these devices are immune to short channel effects, the $SS$ is dominated by $D_{it}$. Therefore, $D_{it}$ can be estimated from $SS$ using the following equation,

$$SS = \frac{60}{300} \left(T + \frac{qD_{it}}{C_{ox}}\right) mV/dec$$

(1)

where $T$ is the temperature in Kelvin, $q$ is the electronic charge, and $C_{ox}$ is the oxide capacitance. 90% of the devices with Al$_2$O$_3$ insertion show $SS$ between 66.0–83.3mV/dec, corresponding to a $D_{it}$ between $1.80 \times 10^{12} - 6.98 \times 10^{12}$ cm$^{-2}$ eV$^{-1}$. Fig. 5(b) shows the transfer characteristics of an 80nm $L_{ch}$ hero Al$_2$O$_3$-first device and a 60nm $L_{ch}$ hero LaAlO$_3$-first device with the lowest $SS = 63$mV/dec and 69mV/dec, respectively. The estimated $D_{it}$ for these two devices are $8.98 \times 10^{11}$ and $2.69 \times 10^{12}$ cm$^{-2}$ eV$^{-1}$. The near-ideal $SS$ is achieved because of the surface area of the nanowires, aggressive $EOT$ scaling, and effective interface passivation.

IV. CONCLUSION

InGaAs GAA nanowire MOSFETs with $L_{ch}$ down to 20nm and $EOT$ down to 1.2nm have been demonstrated, showing excellent gate electrostatic control. The insertion of an ultra-thin 0.5nm Al$_2$O$_3$ between LaAlO$_3$/InGaAs interface has shown to effectively improve the scalability and variability of the devices. Near-60mV/dec $SS$ is achieved on InGaAs nanowires with scaled $EOT$ and effective interface passivation. The InGaAs GAA nanowire MOSFET is a promising candidate for low-power logic applications beyond 10nm.
