Genetic Characterization of *smg-8* Mutants Reveals No Role in *C. elegans* Nonsense Mediated Decay

Jacqueline Rosains, Susan E. Mango*

Introduction

The nonsense mediated decay (NMD) pathway degrades mRNAs bearing premature translation termination codons. In mammals, SMG-8 has been implicated in the NMD pathway, in part by its association with SMG-1 kinase. Here we use four independent assays to show that *C. elegans* smg-8 is not required to degrade nonsense-containing mRNAs. We examine the genetic requirement for *smg-8* to destabilize the endogenous, natural NMD targets produced by alternative splicing of *rpl-7a* and *rpl-12*. We test *smg-8* for degradation of the endogenous, NMD target generated by *unc-54(r293)*, which lacks a normal polyadenylation site. We probe the effect of *smg-8* on the exogenous NMD target produced by *myo-3::GFP*, which carries a long 3’ untranslated region that destabilizes mRNAs. None of these known NMD targets is influenced by *smg-8* mutations. In addition, *smg-8* animals lack classical Smg mutant phenotypes such as a reduced brood size or abnormal vulva. We conclude that *smg-8* is unlikely to encode a component critical for NMD.

Abstract

The nonsense mediated decay (NMD) pathway degrades mRNAs bearing premature translation termination codons. In mammals, SMG-8 has been implicated in the NMD pathway, in part by its association with SMG-1 kinase. Here we use four independent assays to show that *C. elegans* smg-8 is not required to degrade nonsense-containing mRNAs. We examine the genetic requirement for *smg-8* to destabilize the endogenous, natural NMD targets produced by alternative splicing of *rpl-7a* and *rpl-12*. We test *smg-8* for degradation of the endogenous, NMD target generated by *unc-54(r293)*, which lacks a normal polyadenylation site. We probe the effect of *smg-8* on the exogenous NMD target produced by *myo-3::GFP*, which carries a long 3’ untranslated region that destabilizes mRNAs. None of these known NMD targets is influenced by *smg-8* mutations. In addition, *smg-8* animals lack classical Smg mutant phenotypes such as a reduced brood size or abnormal vulva. We conclude that *smg-8* is unlikely to encode a component critical for NMD.

Recently, Yamashita and colleagues used immunoprecipitation of HeLa cell lysates to identify proteins that interact with SMG-1, a phosphatidylinositol kinase-related protein kinase [19,20]. SMG-1 bound two novel, conserved proteins, FLJ23205 and FLJ12898, which were renamed SMG-8 and SMG-9 [21]. This pair bound strongly to each other, and modified SMG-1 kinase activity in vitro. Inactivation of SMG-8 and SMG-9 lead to a partial stabilization of ß-globin mRNAs in mammalian cell culture, suggesting they might play a role in NMD. The authors also used RNA interference (RNAi) to inactivate *C. elegans* smg-8 and smg-9, and concluded that smg-8, but not smg-9, contributed to NMD in worms [21].

Here we examine *C. elegans* smg-8 using a newly generated mutant allele, smg-8(tm2937) contains a 279 bp deletion and a 1 bp insertion within smg-8 (Figure 1A). This deletion encompasses 22 bp upstream of the start site, the initiator ATG and the first two exons. Using animals homozygous for this allele, we employed four approaches to investigate a possible role for smg-8 in the NMD pathway. Our findings suggest that smg-8 is unlikely to be a key component for NMD in *C. elegans*.

Results and Discussion

**smg-8** Mutants do not Exhibit Phenotypes Associated with NMD Mutants

For our first assay, we examined two of the classical phenotypes associated with *smg* genes. Hodgkin and colleagues reported a reduced brood size of 174 (range 147–211) for *smg-1*, which was lower than the mean brood size of wild-type animals (327, range 270–373) [9]. We observed a mean brood size of 301 (range 242–
367, n = 10) for smg-8(2937), similar to the mean brood size of our wild-type strain (279, range 211–328, n = 10) (Table 1). In addition, animals bearing a mutation in a canonical smg gene have a protruding vulva due to morphological defects [9]. However, vulvae appeared normal in smg-8(tm2937) worms (Figure 1B). These data suggest that smg-8(tm2937) animals lack two overt phenotypes associated with canonical smg mutants.

smg-8 does not Show an NMD Phenotype for the Native NMD Target rpl-7a and rpl-12

For our second assay, we examined transcripts for two ribosomal proteins rpl-7a and rpl-12, which are natural NMD targets [4]. These genes each generate two alternatively spliced mRNAs, one of which contains a premature termination codon (PTC; Figure 2A). When NMD is active, the longer isoform containing the PTC is degraded and only the shorter isoform accumulates. When the NMD pathway is compromised, the isoform containing the PTC is stabilized, and both mRNA isoforms accumulate (Figure 2A). Using RT-qPCR primers that flank the PTC, it is possible to distinguish between the two transcripts [4]. smg-8 shows no NMD phenotype by this assay. When a known component of the NMD pathway, such as smg-1, smg-2 or smg-3, is mutated, the mRNA isoform containing the PTC is stabilized, generating a robust upper band (Figure 2B). In contrast, for smg-8(tm2937), a very faint upper band was observed, comparable to that of the wild-type strain (Figure 2B). To extend this result, we inactivated smg-8 and also smg-9 using RNAi, which reduced smg mRNA levels at least five-fold (Figure 2G) and similar to a No Reverse Transcriptase negative control (Figure 2H). The results were again negative for NMD (Figure 2C). RNAi is not always robust; therefore we repeated the assay using the strain eri-6/7(tm1917), which enhances RNAi [22,23], and once more observed no NMD phenotype (Figure 2D). Finally, to exclude the possibility that the tm2937 allele was hypomorphic, we treated smg-8(tm2937) mutants with smg-8 RNAi or smg-9 RNAi, but again we observed no NMD phenotype (Figure 2E). Similar results were observed for rpl-12 (Figure 3).

To quantify these data, we used RT-qPCR to measure the increase of the PTC containing isoform. We observed a fold enrichment of 15 and 38 in smg-1 and smg-3 mutants respectively, compared to the wild-type (Figure 2F). The PTC containing isoform in smg-8 mutants remained similar to the wild-type (0.7 fold enrichment). A virtually identical result was obtained with smg-8 RNAi treatment of smg-8 or eri-6/7 mutant worms (0.7 and 0.4 fold enrichment respectively) (Figure 2F). Together, these data reveal that inactivation of smg-8 fails to stabilize two natural NMD targets, rpl-7a and rpl-12.

Average progeny (n = 10 mothers) at 20°C. Progeny were counted every day until no more progeny were observed.

*Data from [9].

![Figure 1](https://www.plosone.org)
Figure 2. smg-8 lacks an NMD phenotype for the native NMD target rpl-7a. (A) Schematic representation of the two alternatively spliced isoforms of rpl-7a. The isoform containing the premature termination codon (PTC) is subject to degradation by NMD, whereas the shorter isoform is not. RT-PCR was performed using a pair of primers that distinguish the two spliced isoforms (purple arrows). (B) The upper, PTC band is visible only when the NMD pathway is compromised by smg-1, smg-2 or smg-3 mutations (lanes 2, 3 and 4). Only the lower WT band is observed in wild-type (lane 1) and smg-8 mutant (lane 5) animals. (C) Wild-type worms were fed bacteria expressing dsRNA targeting smg-1, smg-8 or smg-9 from the Ahringer dsRNA library [26]. RNA was analyzed as in (B). (D) An enhanced RNAi mutant strain eri-6/7 [22,23] was used and RNAi conducted as in (C). RNA was analyzed as in (B). (E) As in D, using the smg-8(tm2937) mutant strain. (F) RT-qPCR using primers flanking the PTC-containing isoform of rpl-7a, mRNA levels were calculated using the delta-delta-CT method, relative to the control gene pmp-3 [27]. Fold enrichment of the PTC mRNA was normalized to 1 for wild-type. The smg-1 and smg-3 mutants show an enrichment of 15 and 38 fold, respectively. In contrast, in smg-8 mutants, the accumulation of the PTC containing isoform is similar to wild-type (0.7 fold enrichment). smg-8 and eri-6/7 mutant worms treated with smg-8 RNAi
smg-8 is not Required for Endogenous NMD in C. elegans
As a third test for NMD, we examined an endogenous target of the NMD pathway: unc-54(r293) [3,9]. The unc-54 gene generates a muscle myosin heavy chain (MHC) in C. elegans, and the unc-54(r293) allele contains a 256 bp deletion that removes the normal 3’ cleavage/polyadenylation site and most of the 3’UTR [3] (Figure 4A). This deletion causes the production of a long unc-54 mRNA transcript that terminates at a cryptic poly(A) site and renders unc-54 an NMD target. Without the MHC, unc-54 mutant worms are paralyzed (Figure 4B). In the absence of NMD components such as smg-1, the unc-54(r293) mRNA is stabilized, wild-type protein is produced, and the Unc phenotype is suppressed [3] (Figure 4B). We generated unc-54(r293); smg-8(tm2937) double mutants and observed no suppression of the paralysis phenotype (Figure 4B), consistent with our hypothesis that smg-8 is not required for NMD in C. elegans.

smg-8 does not Restore Expression the Exogenous NMD Target myo-3::GFP
As a fourth test for NMD, we examined an exogenous NMD target, myo-3::GFP. This strain carries a transgenic GFP reporter that is transcribed in body wall muscles and targeted for degradation by a long 3’UTR (Figure 5A) [24]. When the NMD pathway is inactive, GFP accumulates in muscle fibers, whereas wild-type worms accumulate almost no GFP (Figure 5B). We created double combinations of myo-3::GFP and smg-1, smg-3 or smg-8. The strain myo-3::GFP; smg-8(tm2937) accumulated very little GFP compared to the positive controls myo-3::GFP; smg-1(r861) or myo-3::GFP; smg-3(867) (Figure 5B), indicating that smg-8 is not required for exogenous NMD in C. elegans.

In summary, we tested smg-8 for a role in NMD using four different assays: i) anatomical phenotype and brood size, ii) accumulation of natural NMD targets rpl-7a and rpl-12, iii) rescue of the paralysis phenotype caused by the endogenous NMD target unc-54(r293) and iv) GFP accumulation of the exogenous NMD target reporter myo-3::GFP. The discrepancy between our study and the results presented by Yamashita and colleagues is due in part to the use of an allele (our study) vs. RNAi [21]. In addition, we note that the effect of smg-8 inactivation on NMD in C. elegans was not robust in the Yamashita study [21]. In all of our assays, smg-8 mutants resembled wild-type worms and differed from classical smg mutants. We detected no accumulation of mRNA or protein in smg-8 mutants, even when the smg-8 mutation was combined with RNAi. We suggest that smg-8 in C. elegans is a novel, conserved gene whose function remains to be elucidated.

Materials and Methods

Strains
Worm growth and maintenance were performed as described before [25]. Strains used: SM1618 unc-54(r293)I, SM456 smg-1(r861)I, SM436 smg-3(2008)I, SM196 smg-3(r867)IV, smg-1(r861)unc-54(r293)I, smg-8(tm2937)I unc-54(r293)I, CL724 dvb38 [pCL60 (Pmyo-3::GFP::degron/long 3’ UTR)+pRF4], SM1944 smg-1(r861)myo-3::GFP, SM1929 smg-3(867)IV::myo-3::GFP, SM1937 smg-8(tm2937)I;myo-3::GFP, SM1881 smg-8(tm2937)I eight times outcrossed.

RNA interference
HT115 bacteria expressing double stranded RNA targeting smg-1, smg-8 or smg-9 grown for ~8 hours at 37°C were plated using 1 mM IPTG (Sigma) and 50 mg/ml of Carbenicillin (Sigma). RNAi clones were derived from the Ahringer library [26] and verified by sequencing. Five wild-type, smg-8(tm2937) or eri-6/7(tm1917) worms were transferred at the L4 stage to RNAi plates and allowed to lay embryos for one day. The progeny was collected ~48 hours later, when most worms had grown at least to the L4 stage, by rinsing with water and frozen at -80°C for subsequent analysis.

Figure 3. smg-8 lacks an NMD phenotype for the native NMD target rpl-12. (A) RT-PCR was performed using a pair of primers that distinguish the two spliced isoforms of rpl-12; the upper, PTC band is visible only when the NMD pathway is compromised by smg-1, smg-2 or smg-3 mutations (lanes 2, 3 and 4). Only the lower, WT band is observed in wild-type (lane 1) and smg-8 mutant (lane 5) animals. (B) Wild-type worms were fed bacteria expressing dsRNA targeting smg-1, smg-8 or smg-9 from the Ahringer dsRNA library [26]. RNA was analyzed as in (A). (C) As in (B), using an enhanced RNAi mutant eri-6/7 [22,23]. (D) As in (B), using the smg-8(tm2937) mutant strain.

doi:10.1371/journal.pone.0049490.g003
subsequent RNA extraction. Nine 35 mm plates were used per strain per experiment.

RNA Extraction
For total RNA extraction, glass beads (Sigma) and 1 ml of Trizol Reagent (GibcoBRL) were added to frozen worm pellets. Pellets were lysed by vortex followed by chloroform extraction. RNA was precipitated with isopropanol and washed with 70% ethanol. Resuspended RNA was extracted with phenol:chloroform and precipitated with ethanol. A first-strand reaction kit (NEB) was used to perform the reverse transcriptase reaction, following the manufacturers protocol.

RT-PCR of rpl
Amplification of rpl-7a from the cDNA was performed as described in [4], and PCR product was analyzed in a 1% agarose gel. Primers used were rpl-7a-fw GACATCCAGCCAAA-GAAGGA and rpl-7a-rv AACGGTGTTTGGTCTCTTGG.

Primers for rpl-12 are Rpl-12-F1 ACCCAAGACTGGAGGGGTCT and Rpl-12 R1 GCCATCGATCTTGGTCAT.

RT-qPCR
For smg-8 and rpl-7a, mRNA levels were calculated using the delta-delta-CT method, relative to the control gene pmp-3 [27]. Control mRNA was normalized to 1 and the mRNA levels are shown as relative fold change. Primers for smg-8 were smg8-fw-4348 GCTGCCAATATTTCCATCGT and smg8-rv-5165 TGACCACGGGAACATTCATA.

Brood Size
10 worms at the L4 stage were picked into individual plates at 20°C. Their progeny was counted everyday until no more progeny was generated. The number of progeny per plate was averaged (n = 10).

Figure 4. smg-8 is not required for endogenous NMD in C. elegans. (A) unc-54 gene schematic. The r293 allele contains a 256 bp deletion within unc-54 that includes the 3’ cleavage and polyadenylation site. (B) smg-8(tm2937) or smg-1(r861) mutations were combined with unc-54(r293). Two worms were placed in the middle of the bacterial lawn and allowed to crawl for 45 minutes. Wild-type worms that crawl (top left) leave tracks in the lawn whereas unc-54(r293) mutants cannot move well (top right). smg-1(r861) suppresses unc-54(r293) mRNA degradation and restores movement [3] (bottom left). In contrast, smg-8 does not suppress the paralysis phenotype (bottom right). Arrowheads indicate the tracks left by paralyzed worms.
