Abstract

Cysteinyl leukotrienes (cys-LTs), comprising LTC₄, LTD₄, and LTE₄, are a group of lipid mediators that are potent bronchoconstrictors, powerful inducers of vascular leakage and potentiators of airway hyperresponsiveness. Cys-LTs play an essential role in asthma and are synthesized as well as activated in mast cells (MCs). Cys-LTs relay their effects mainly through two known GPCRs, CysLT₁R and CysLT₂R 

Introduction

Cysteinyl leukotrienes (cys-LTs), comprising LTC₄, LTD₄, and LTE₄, are potent bronchoconstrictors and mediators of pulmonary inflammation [1,2]. They are derivatives of arachidonic acid generated by mast cells (MCs), eosinophils, basophils, macrophages, and myeloid dendritic cells [3]. LTC₄ and LTD₄ are very short-lived in vivo while LTE₄ is stable, being the only cys-LT detected in biologic fluids and excreted in the urine [4]. Cys-LTs potentiate airway hyperresponsiveness (AHR) to histamine when administered by inhalation to human subjects [5]. Bronchoalveolar lavage (BAL) fluids collected from allergic human subjects after endobronchial challenge with allergen contain high levels of cys-LTs [6], pointing the role of cys-LTs in allergic inflammation. This role is confirmed by the fact that inhibitors of the type 1 G protein-coupled receptor (GPCR) for cys-LTs (CysLT₁R) [7,8] and inhibitors of CysLT₁R synthesis [9] are clinically efficacious for the treatment of asthma. Cys-LTs are also implicated in adaptive immunity and fibrosis [10,11,12]. Most of these cys-LT-mediated effects are thought to be induced through CysLT₁R and a second GPCR, CysLT₂R [13,14], although the existence of additional receptors is likely based on findings in mice lacking both receptors [15,16,17]. Identification of signaling partners and mechanisms involved in the regulation of these receptors is crucial to gain insight into allergic inflammation.

MCs are stem cell factor (SCF)-dependent hematopoietic cells that are ubiquitously distributed throughout the body [18,19] and initiate inflammatory responses to allergens and infectious agents. They play an important role in triggering exacerbations of asthma through the elaboration of several soluble inflammatory mediators including cys-LTs, histamine, serine proteases, multiple cytokines and chemokines. MCs not only generate cys-LTs, but also express both CysLT₁R and CysLT₂R [20,21] and respond to LTC₄, LTD₄, and LTE₄ with a range of functions. We have demonstrated earlier that stimulation of human cord blood-derived MCs (hMCs) and/or LAD2 cells with LTD₄ potently induces calcium flux [22,23] and cytokine generation [22,23], each of which requires CysLT₁R based on pharmacologic antagonism by MK571. hMCs also proliferate in response to LTD₄, reflecting transactivation of c-kit by CysLT₁R [24]. The relevance of cys-LTs to MC function is suggested by the observation that mice lacking the requisite terminal enzyme needed for cys-LT generation, leukotriene C₄ synthase, show markedly reduced numbers of MCs in the airway mucosa following sensitization and challenge to allergen [12]. However, aside from the ability of LTD₄ to transactivate c-kit [24] and for LTE₄ to activate PPARγ [22] and induce the formation of large amounts of cytokines by a pathway involving the P2Y₁₂ receptor [17], little is understood concerning the signaling mechanisms by which cysteinyl leukotriene receptors modulate the function of MCs.

Protein kinase C (PKC) refers to a family of phospholipid-dependent serine/threonine protein kinases that are activated by a number of extracellular stimuli including growth factors, adhesion, cytokines and GPCRs [25]. PKCs are involved in signal transduction associated with cell proliferation, differentiation, and apoptosis. At least eleven closely related PKC isoforms have been reported to differ in their structure, biochemical properties, tissue distribution, subcellular localization, and substrate specificity. They are classified as classical (α, β1, β2, γ), novel (δ, ε, η, θ, μ), and atypical (ζ, ι, λ) isoforms depending on their requirement for the cofactors calcium, diacylglycerol (DAG) and phosphatidylinositol (PS) [26,27,28]. PKCs are implicated in the negative regulation of LTD4-induced calcium signaling [29,30]. Global pharmacological inhibition of PKCs was shown to inhibit LTD4-mediated CysLT1R internalization and desensitization resulting in enhanced phosphoinositide production and calcium flux [31]. This CysLT1R desensitization is shown to occur mainly through the phosphorylation of three serine residues (313–316) in the tail of CysLT1R by PKCζ [31]. In contrast, Thodeti et al., demonstrated that PKCζ regulates LTD4-induced Ca2+ signal in intestinal epithelial cells [32]. Overall, it is not clear what specific isoforms are activated by cysteinyl-leukotrienes (cys-LTs) in mast cells (MCs) or how they are involved in regulating cys-LT-induced MC responses. We show that both PKCα and PKCζ isoforms activated in MCs by cys-LTs and the role of each isoform activation. In the present study, we investigated the specific PKC isoforms activated in MCs by cys-LTs and the role of each isoform in regulating cys-LT-induced MC responses. We show that both LTD4 and LTE4 activate PKCζ and PKCα isoforms and that these isoforms regulate different signals down-stream of CysLT1R. Specifically, PKCζ negatively regulates cys-LT-induced calcium flux, while PKCα positively regulates CysLT1R-mediated c-fos expression and MIP1β generation.

Materials and Methods

Reagents

LTD4, LTE4 and MK571 were purchased from Cayman Chemical. Fura-2 AM was from Molecular Probes, All phospho-specific antibodies were from Cell Signaling Technology, Total PKC antibodies were from Santa Cruz Biotechnology. Isoform specific siRNAs for PKCs were obtained from Dharmacon and MIP1β Elisa kit was from Endogen.

Cell Culture

The LAD2 MC leukemia line [33] was a kind gift from Dr. Arnold Kirshenbaum, NIH. These cells were cultured in stempro-34 (Invitrogen) supplemented with 2 mM L-Glutamine (Invitrogen), Pen-strep (100 IU/ml) (Invitrogen) and SCF (endoegen) (100 ng/ml). Cell culture medium was hemi-depleted every week with fresh medium and 100 ng/ml SCF. Primary hMCs were derived from cord blood mononuclear cells cultured for 6–9 weeks in RPMI supplemented with SCF, interleukin IL-6, and IL-10 [34].

Calcium Flux

LAD2 cells or hMCs (0.5–1×10⁶/sample) were washed and labeled with fura-2 AM for 30 minutes at 37°C. Cells were stimulated with the indicated concentrations of LTD4 and LTE4 and the changes in intracellular calcium were measured using excitation at 340 and 380 nm in a fluorescence spectrophotometer (Hitachi F-4500) as described earlier [22]. The relative ratios of fluorescence emitted at 510 nm were recorded and displayed as a reflection of intracellular calcium concentration. In some experiments, cells were pre-incubated with the PKC inhibitor GF109203X (GFX; 2 μM) for 30 minutes or with CysLT1R antagonist MK571 (1 μM) for 15 minutes before the stimulation with cyst-LTs (500 nM).

Cell Activation

LAD2 cells were either stimulated with 500 nM of LTD4 or LTE4 (unless specified otherwise), pre-treated with GFX (2 μM) for 30 minutes or MK571 (1 μM) and stimulated for 15 minutes for the phosphorylation of Erk and CREB or 1 h for the expression of c-fos or 6 h for the measurement of cytokines. The concentration of MIP1β (Endogen) was measured with ELISAs according to the manufacturer’s protocol [22]. Transfection of LAD2 cells with CysLT1R siRNA resulted in a reduction of CysLT1R expression by ~70%. Normalization was determined using Gapdh as an internal control.

Cell Lysates and Western Blotting

After stimulation with the respective agonists, LAD2 cells (0.5–1×10⁶) were washed with lysis buffer (BD Bioscience) supplemented with protease inhibitor cocktail (Roche) and phosphatase inhibitor cocktail (pierce). Immunoblotting was performed as described previously [35]. Brieﬂy, lysates were subjected to 4–12% SDS-PAGE and transferred to PVDF membrane. Membranes were incubated with respective primary phospho- and total antibodies diluted in 1x TBS, 5% dry milk, 0.1% Tween-20 (1:1000) overnight at 4°C on shaker, and then with secondary antibody (peroxidase-conjugated anti-rabbit or anti-mouse). Western blot was incubated with ECL and the bands were visualized using imager (Protein Simple) and quantified using Image J (NIH).

Statistics

Data are expressed as mean ± SD from at least three experiments except where otherwise indicated. Data were converted to a percentage of control for each experiment where indicated. Significance was determined using Student’s t test as well as one-way ANOVA followed by Tukey post-hoc analysis.

Results

Cys-LT-mediated Calcium Flux in Mast Cells is Negatively Regulated by PKC

We have reported earlier that cysteinyl-leukotrienes (cys-LTs), notably LTD4, potently induces calcium flux in primary hMCs [21] and also in LAD2 cells [22]. This signal was sensitive to inhibition by MK571, implying a requirement for CysLT1R or a CysLT1R-like GPCR in this signaling event. CysLT1R undergoes ligand-induced desensitization and internalization in heterologous cell systems and these processes are uniquely dependent on PKCζ [31]. Based on these observations, we sought to determine if PKCs have a role in controlling cys-LT-dependent calcium flux in MCs. Both hMCs and LAD2 cells were pre-treated with GF109203X (GFX), a global PKC inhibitor, and its effect on LTD4 or LTE4 stimulation was evaluated. In the absence of GFX, LTD4 (500 nM) potently stimulated calcium flux in both cell types, but LTE4 (500 nM) only caused minimal calcium flux. However, GFX treatment markedly potentiated LTD4 and LTE4-mediated calcium fluxes in both cell types (Fig. 1 A, B). Importantly, a specific antagonist of CysLT1R, MK-571, completely abolished both LTD4 and LTE4-mediated calcium fluxes in the presence of GFX (Fig. 1C). These observations suggest that the strength of calcium signaling through CysLT1R is negatively regulated by PKCs, probably through the desensitization of the receptors [31,36].
PKCs are Required for cys-LT-mediated Phosphorylation and Expression of c-fos

In rat basophilic leukemia (RBL) cells, Ng et al., demonstrated that disrupting CysLT1R desensitization by PKC inhibitors can lead to enhanced LTC4-induced calcium influx, but prevents up-regulation of c-fos expression through the CRAC channels. Along these lines, we first checked if stimulation of MCs with LTD4 and LTE4 induced c-fos expression (Fig. 2). We found that both LTD4 and LTE4 induced robust activation of c-fos at the transcript level as well as at the protein level. Surprisingly, the induction of c-fos transcript was maximum at 30 minutes, while the protein induction was as early as 30 minutes with peak expression at 1 h and then slowly began to decline after stimulation with either LTD4 or LTE4 (Fig. 2A, B). To determine the potency of cys-LTs to induce the expression of c-fos, we treated LAD2 cells with various concentrations of LTD4 and LTE4 and analyzed phosphorylation and induction of c-fos (Fig. 2C). LTD4 caused c-fos induction at doses as low as 1 nM while LTE4 evoked similar response at relatively higher concentrations (100 nM and 500 nM). On average, we found that 500 nM concentration of cys-LTs evoked the best response of all the experiments performed and hence we stimulated cells with 500 nM of cys-LTs in all the concurrent experiments. Also, we observed that the pattern of phosphorylation as well as expression of c-fos were similar with both LTD4 and LTE4, suggesting that cys-LTs not only induced the expression of c-fos but also activated c-fos. We then asked if cys-LT-induced c-fos expression and activation are sensitive to PKC inhibition and are mediated through cysLT1R. Both LTD4 and LTE4-induced c-fos activation as well as expression was inhibited by GFX as well as MK571 (Fig. 2D). These results suggest that though PKCs negatively regulate cys-LT-mediated calcium flux, but are required for cys-LT-mediated c-fos phosphorylation/expression.
MIP1β Generation by cys-LTs is Positively Regulated by PKCs

Next, we investigated the effect of PKC inhibition on other cys-LT-induced MC functions. We have shown earlier that cys-LTs are capable of potently activating inflammatory chemokine, MIP1β in MCs [22]. Hence, we asked if PKCs play a role in cys-LT-induced inflammatory responses such as MIP1β production in MCs. To determine this, LAD2 cells were pre-treated with GFX with or without cys-LT stimulation and MIP1β was measured in the supernatants. As reported earlier [22] and shown in Fig. 3, both LTD4 and LTE4 potently induced MIP1β generation. Importantly, unlike calcium flux, MIP1β induction by both the agonists was significantly blocked by PKC inhibition with GFX (Fig. 3). These findings suggest the PKCs differentially regulate cys-LT-induced calcium influx and gene expression in MCs, possibly via activation of distinct isoforms of PKCs.

PKCs do not Effect cys-LT-activated ERK, or CREB Pathways

We have shown earlier that cys-LTs activate ERK and CREB [22] and we sought to investigate if all cys-LT-induced effects are mediated through PKCs. To our surprise, PKC inhibition by GFX had no significant effect on the phosphorylation or the expression of ERK and CREB by cys-LTs (Fig. 4). These results suggest that cys-LTs have potential to modulate MC function, both dependent as well as independent of PKCs.

PKC Profile in MCs and Identification of cys-LT-responsive PKC Isoforms

To determine which of the PKC isoforms mediate cys-LT signaling responses, we first characterized the expression of different isoforms of PKCs in MCs including classical PKCs (α, βI, βII, γ), novel PKCs (δ, ε, η, θ), and atypical PKCs (ζ, τ/λ, μ) by Western blotting. We found that MCs express PKCα, PKCβII, PKCγ, PKCδ, PKCe, and PKCf isoforms (Fig. 5A) and not PKCβI, PKCε, PKCθ, and PKCζ isoforms (data not shown). We next asked which of the expressed PKC isoforms are activated by cys-LTs. Cys-LT responsive PKC isoforms were determined by analyzing the phosphorylation of individual PKC isoforms in response to cys-LTs using phospho-specific antibodies. We found that PKCα and PKCe are phosphorylated by both LTD4 and LTE4 in a time dependent manner (Fig. 5B, C), but not PKCβI, PKCγ, PKCδ, PKCε, PKCθ, and PKCζ isoforms (data not shown). Phosphorylation of both PKCα and PKCe in response to cys-LTs was rapid and transient reaching a peak at 15 minutes and started to decline after 30 minutes. The peak LTE4-induced phosphorylation of PKCe, but not of PKCα was more gradual than that induced by LTD4. The small inhibition in the phosphorylation of PKCe that we observed at 10 minutes compared to 5 minutes in response to LTE4 is not statistically significant.

PKCα Negatively Regulates cys-LT Mediated Calcium Flux While PKCe is Essential for MIP1β Generation by cys-LTs

After determining that LTD4 and LTE4 both activated PKCα and PKCe in MCs, we investigated the specific roles of PKCα and PKCe in cys-LT-mediated calcium flux, c-fos expression and MIP1β production (Fig. 6). To determine this, we first knocked down PKCα and PKCe isoforms in LAD2 cells by transfecting isoform specific siRNAs (10 nM) against PKCα and PKCe. As a control, we transfected cells with a non-specific siRNA pool. Transfection of MCs with PKCα and PKCe siRNAs significantly down regulated PKCα and PKCe expression (40.0±4.3% and 41.5±9.2% down regulation), respectively (Fig. 6A). Down regulation of PKCα with PKCα siRNA did not have any significant effect on the expression of PKCe and vice versa (data not shown). We then assessed cys-LT mediated calcium influx, c-fos phosphorylation, expression and MIP1β generation in these cells. Calcium measurements revealed that knock down of PKCα induced a significant two fold increase in LTD4-induced peak calcium influx in MCs (Fig. 6B, C). We did not detect any change in calcium flux induced by LTD4 in PKCe knocked-down MCs suggesting that PKCα is the key isoform involved in the negative regulation of cys-LT induced calcium flux. On the other hand, knockdown of PKCe attenuated both LTD4 and LTE4-induced c-fos expression (Fig. 6D, E) and phosphorylation (data not shown). Knock down of PKCe also attenuated cys-LT-induced MIP1β production in MCs (53% and 55% respectively) (Fig. 6F). Transfection with control siRNAs did not affect LTD4 and LTE4-induced c-fos expression or MIP1β generation. Although PKCα knock down marginally inhibited MIP1β generation, this signal is not significantly different from control siRNA.
Discussion

In the present study, we demonstrate that cys-LTs activate two isoforms of protein kinases, PKCα and PKCε, and that these two isoforms differentially regulate cys-LT-mediated MC function. PKCε is essential for cys-LT-mediated c-fos expression and MIP1β generation, while PKCα negatively regulates cys-LT-induced calcium flux (schematic, Fig. 7). Surprisingly, PKCs appear to be dispensable for expression and activation of ERK and CREB.

MCs are relevant cellular effectors of asthma and other allergic diseases, and cys-LTs are pertinent mediators of the same processes [37]. The mechanisms that control cys-LT-dependent biological responses are of considerable pathobiologic and clinical interest in both allergic and non-allergic disease [38]. We have previously demonstrated that cys-LTs induce robust calcium flux in hMCs [21,23] and LAD2 cells via CysLT1R (based on pharmacologic interference using selective antagonists) [22]. We have shown earlier that MK571 specifically blocks calcium flux and Erk phosphorylation in CHO cells expressing CysLT1R, but not CysLT2R suggesting its specificity [22]. MK571 is also reported to have inhibitory activity against MRP1 [39]. Further, it was shown that MK571 treatment increased intracellular LTC4 concentration in cosinophils and modulate IL-4 levels from preformed vesicles via a putative intracellular CysLT receptor [40]. However, cys-LT-induced inflammatory mediator production in MCs require de novo transcriptional and translational mechanisms and no such putative intracellular CysLTR has been identified. Therefore, we believe that the observed inhibitory effects of MK571 are mostly directed at CysLT1R on the plasma membrane. In the current study, we elucidate that pharmacological inhibition of PKCs followed by stimulation of cells with cys-LTs resulted in significant augmentation of calcium flux in MCs. This finding is consistent with desensitization of CysLT1R by PKCs reported in other cell systems. Crooke and colleagues observed that LT4 activates PKC, and the same research team [29,41] noted that inhibitors of PKC increased the mobilization of Ca2+ induced by LT4 in the leukemic cell line RBL-1 using pharmacological activators and inhibitors. Winkler et al. [30] have reported that the broad PKC inhibitor staurosporine potentiated the LT4-induced Ca2+ signal in differentiated U-937 cells. In COS-1 cells overexpressing CysLT1R, pharmacological inhibition of PKC activity was shown to enhance calcium mobilization stimulated by LT4 [31]. However the exact molecular mechanism(s) underlying this process are not well known.

Enhanced receptor activation is usually translated into increased receptor function. Relief of PKC-mediated desensitization of endogenous CysLT1R augments multiple LT4-stimulated cellular functions, with associated increases in intracellular signaling events [42]. However, while our data indicate that PKC inhibition augmented cys-LT-induced calcium signaling, we also found that it suppressed cys-LT-induced c-fos expression and chemokine secretion. Activation of c-fos by LT4 has been reported previously in HEK cells expressing CysLT1R [43]. Recently, Ng et al., reported that LTC4-mediated CysLT1R is desensitized by PKC-dependent phosphorylation and that prevention of this signaling by PKC inhibition led to loss of calcium-dependent gene expression, despite potentiation of Ca2+ release [36]. This signal was proposed to delay the activation of CRAC channels resulting in the decreased c-fos expression. In the present study using LAD2 cells, we observed that both LT4 and LTE4 significantly increased the expression of c-fos, consistent with the earlier study.

Data shown are ± SD of three separate experiments.

doi:10.1371/journal.pone.0071536.g005
Our data demonstrate that LTD₄ and LTE₄ also induce c-fos phosphorylation. This increase in phosphorylation and expression of c-fos is mediated through an MK-571 sensitive CysLTR and PKC. Since cys-LTs activate both Erk and CREB [22], we investigated if PKC inhibition altered cys-LT-mediated phosphorylation of these signaling molecules. Although cys-LTs robustly enhanced phosphorylation of Erk and CREB, inhibition of PKCs surprisingly had no effect on this signal. These findings suggest that modulation of PKC activity may couple CysLTR signaling to distinct signaling pathways. It is also possible that at least some of the PKC-independent signaling events may occur through receptors other than CysLT1R.

Despite the fact that cys-LT-mediated calcium signaling was enhanced by global PKC inhibition (Fig. 1), c-fos expression and MIP1β generation was substantially suppressed. While this finding could reflect a requirement for CysLT1R receptor desensitization to facilitate gene induction as suggested by the Ng et al., it also suggested that cys-LTs activate more than one PKC isoform in MCs. Indeed, we found that MCs express PKC α, βII, γ, δ, ε, θ and ζ isoforms but only PKCα and PKCe were phosphorylated in response to cys-LTs. Notably, we found that PKCα knockdown significantly augments calcium flux, but has little effect on cys-LT-induced c-fos and MIP1β production. However, knockdown of
PKCε significantly attenuated cy3-LT-induced c-fos phosphorylation, expression and MIP1β production without altering calcium flux. Activation of PKCε by cy3-LTs has been showed in other systems [17,32,44] as well. Interestingly, PKCε was shown to be essential for LTD4-induced calcium signal in intestinal epithelial cells [22], implying coupling of cy3-LTs to signaling events is regulated in a cell type-specific manner. In conclusion, our study identifies specific isoforms of PKCs, PKCε and PKCδ that are activated by cy3-LTs and differentially regulate distinct MC functions, critical for the progression and pathology of asthma.

Understanding the signaling and players involved in CysLTR regulation can be useful in identifying better therapeutic targets for inflammatory asthma and allergic diseases.
