Background—New antiplatelet agents that provide greater, more consistent inhibition of the platelet ADP receptor P2Y$_{12}$ may be used in combination with glycoprotein (GP) IIb-IIIa antagonists, but their combined effect on platelet function and procoagulant activity is not well studied. Therefore, the objective of this study was to evaluate the independent and complementary effects of P2Y$_{12}$ and GPIIb-IIIa inhibition on platelet function and procoagulant activity.

Methods and Results—Healthy donor blood was treated with the active metabolite of prasugrel (R-138727 $5\text{ mol/L}$), GPIIb-IIIa antagonists (abciximab $3\text{ g/mL}$ or eptifibatide $0.9\text{ g/mL}$), and combinations thereof, exposed to physiologically relevant agonists (collagen and ADP) and then evaluated for markers of platelet activation and procoagulant activity. Significant interactions between R-138727 and GPIIb-IIIa antagonists were observed. R-138727 and the GPIIb-IIIa antagonists had additive inhibitory effects on collagen-stimulated platelet aggregation and on the collagen plus ADP–stimulated level of activated platelet surface GPIIb-IIIa. R-138727 and abciximab each inhibited collagen plus ADP–stimulated platelet phosphatidylserine expression and prothrombin cleavage, and the combination produced greater inhibition than achieved with abciximab alone. In contrast, eptifibatide did not inhibit, but instead enhanced, collagen plus ADP–stimulated prothrombin cleavage. Addition of R-138727 reduced prothrombin cleavage in eptifibatide-treated samples, suggesting a novel mechanism for potential benefit from combined prasugrel and eptifibatide treatment.

Conclusions—The complementary effects of abciximab and R-138727 on platelet activation, aggregation, and procoagulant activity suggest their combined use may, to a greater degree than with either agent alone, reduce thrombus formation in vivo. (J Am Heart Assoc. 2013;2:e000026 doi: 10.1161/JAHA.113.000026)

Key Words: glycoprotein IIb-IIIa receptor antagonists • platelets • prasugrel
inhibition and may have clinical benefits in patients, particularly patients with large thrombus burden or poor response to oral antiplatelet agents.\textsuperscript{2,4,6} Although combination GPIIb-IIIa and P2Y\textsubscript{12} inhibition on an aspirin background is used in the clinical setting, the combined effect of these inhibitors on platelet responses has not been well studied, particularly in the case of the newer P2Y\textsubscript{12} agents.

In vitro studies, the active metabolite of prasugrel, R-138727, in the absence or presence of aspirin, inhibits platelet activation as well as platelet procoagulant and proinflammatory responses;\textsuperscript{7,9} however, the effect of concomitant prasugrel and GPIIb-IIIa antagonist treatment on these end points remains unknown. Therefore, the objective of this study was to evaluate the independent and complementary effects of P2Y\textsubscript{12} and GPIIb-IIIa inhibition on platelet function. On a background of aspirin, we evaluated the combined effect of in vitro treatment of whole blood with the active metabolite of prasugrel, R-138727, plus abciximab or eptifibatide on platelet activation, aggregation, and procoagulant activity.

**Methods**

**Materials**

ADP was purchased from Bio/Data Corporation, and fibrillar type I collagen was purchased from Chrono-log. Gly-Pro-Arg-Pro (GPRP) was purchased from Bachem. The type I collagen was purchased from Chrono-log. Gly-Pro-Arg-Gly-Pro (GPRG) was purchased from Bachem. The fluorogenic activated factor XIII (FXIIIa) substrate was from Zedira. Fluorescein isothiocyanate (FITC)-conjugated annexin V, FITC-labeled PAC1 (an IgM monoclonal antibody [mAb] specific for the activated conformation of GPIIb-IIIa), phycoerythrin (PE)-Cy5–conjugated CD42b-specific mAb, and PE-conjugated CD42a- and CD62P-specific mAbs were from Becton Dickinson. PE-Cy5–labeled CD14-specific mAb was from Beckman Coulter. FITC-conjugated anti–tissue factor mAb (clone VD8) was from American Diagnostica. Purified human coagulation factors Va and Xa (FvA and FXa, respectively) were purchased from Haematologic Technologies. The prothrombin fragment 1.2 (F1.2) ELISA was from Dade Behring.

**Blood Collection and Treatment**

Institutional review board–approved written informed consent was obtained from all subjects. Two hours after healthy volunteers ingested aspirin 325 mg (Bayer HealthCare), blood was collected into a fl

DOI: 10.1161/JAHA.113.000026
ADP 20 μmol/L or no agonist (HEPES-Tyrode’s buffer) for 20 minutes at 37°C. Phosphatidylserine expression on the platelet surface was determined by annexin V binding as previously described. Briefly, after incubation with collagen plus ADP or buffer, samples were mixed with FITC-conjugated annexin V and a PE-Cy5 anti-CD42a antibody (as a platelet identifier) in the presence of CaCl₂ 4 mmol/L, incubated for 15 minutes at room temperature, and fixed with 1% formaldehyde in HEPES-saline. Flow cytometric analysis was performed in a calibrated Becton Dickinson FACSCalibur.

Tissue Factor Expression on Monocyte–Platelet Aggregates and Single Platelets

The presence of monocyte–platelet aggregates and the expression of tissue factor on monocyte–platelet aggregates and single platelets were detected, as previously described, in PPACK-anticoagulated whole blood stimulated with collagen 20 μg/mL plus ADP 20 μmol/L or no agonist (HEPES-saline). In brief, whole blood was incubated with agonists for 15 minutes at room temperature and then incubated with a mixture of PE anti-CD42a 1 μg/mL for platelet identification, PE-Cy5 anti-CD14 for monocyte identification, and FITC-conjugated anti–tissue factor mAb 10 μg/mL for 20 minutes at room temperature. After incubation, FACS Lysing solution (Becton Dickinson) was added to samples, and flow cytometric analysis was performed in a Becton Dickinson FACSCalibur.

Thrombin Generation

Hirudin-anticoagulated whole blood was mixed for 15 minutes at 37°C with shaking with FXa 600 pmol/L and FVa 300 pmol/L combined with either collagen 20 μg/mL plus ADP 20 μmol/L or no agonist (HEPES-Tyrode’s buffer) in a 96-well microtiter plate (total volume 100 μL, all concentrations are final concentrations in whole blood). The assay was stopped by the addition of 260 μL of EDTA 2 mmol/L in HEPES-saline. Samples were centrifuged and thrombin generation was measured by the formation of F1.2 in the supernatant using the Enzygnost F1.2 ELISA.

Activated FXIII Generation

For FXIII assays, blood was collected from healthy volunteers into sodium citrate, 24 hours after ingestion of aspirin 325 mg. As described earlier, blood was treated with R-138727, abciximab, and epifibatide, and PRP was prepared via centrifugation. Sodium citrate–anticoagulated PRP was combined with FXIIIa substrate solution (fluorogenic FXIIIa substrate 56 μmol/L, CaCl₂ 20 mmol/L, FXa 60 pmol/L, FVa 30 pmol/L, and GPRP 10 mmol/L) and collagen 20 μg/mL plus ADP 20 μmol/L or no agonist (HEPES-saline) in a 96-well microtiter plate (all concentrations are final concentrations in PRP). Fluorescence was monitored (excitation at 313 nm and emission at 418 nm) in a microtiter plate reader for 45 minutes at 37°C with shaking. PPACK-treated PRP was used as the plate blank.

Statistical Methods

Data analyses were performed by the authors using GraphPad Prism Version 5.0 and VassarStats: Website for Statistical Computation. Data are presented as mean±SEM from 6 independent experiments. The effects of R-138727, the GPIIb-IIIa antagonists, and the interactions between R-138727 and the GPIIb-IIIa antagonists were determined by 2-factor repeated measures ANOVA (RM-ANOVA) with P<0.05 considered statistically significant. Posttests to compare individual treatment conditions assumed samples were from normal distributions and were by Student’s paired t test or by 1-sample t test (for comparison with a normalized baseline result). To account for multiple comparisons, only posttest P values <0.0071 (Bonferroni correction) were considered significant.

Results

Inhibition of Platelet Aggregation by P2Y₁₂ and GPIIb-IIIa Antagonists

The P2Y₁₂ antagonist R-138727 has been previously shown to dose-dependently inhibit ADP-induced platelet aggregation. To investigate the combined effect of P2Y₁₂ and GPIIb-IIIa inhibition on a background of aspirin, platelet aggregation was studied in PRP from aspirin-treated subjects, treated in vitro with R-138727 alone or in combination with the GPIIb-IIIa antagonists, abciximab or epifibatide. Consistent with previous studies, when platelets were stimulated with ADP, aggregation was significantly inhibited in the presence of R-138727 (Figure 1). Likewise, as expected, treatment with either GPIIb-IIIa antagonist resulted in a marked decrease in ADP-induced aggregation. However, the addition of either abciximab or epifibatide to R-138727 completely abrogated platelet aggregation (Figure 1). Two-factor RM-ANOVA of ADP-induced platelet aggregation (Table) showed a significant effect of both R-138727 (P<0.0001) and the GPIIb-IIIa antagonists (P<0.0001) and a significant interaction between R-138727 and the GPIIb-IIIa antagonists (P=0.0009). When collagen was used as the agonist, the presence of R-138727 resulted in a smaller, but still significant, decrease in maximal platelet aggregation (Figure 1). As with ADP-induced aggregation, the GPIIb-IIIa antagonists significantly inhibited collagen-induced platelet aggregation compared with vehicle. Combined treatment with R-138727 plus abciximab or
epitifibatide resulted in a markedly reduced aggregation response compared with R-138727 treatment alone (Figure 1). Furthermore, when R-138727 was added to the GPIIb-IIIa antagonists, platelet aggregation was decreased beyond the level of aggregation with GPIIb-IIIa inhibition alone.

**Platelet Surface Activated GPIIb-IIIa and P-selectin**

Because platelet aggregation is dependent on the activation of GPIIb-IIIa, the combined effect of P2Y12 and GPIIb-IIIa inhibition on the expression and availability of activated GPIIb-IIIa was evaluated in whole blood treated with R-138727 alone or in combination with abciximab or epitifibatide. After stimulation with collagen plus ADP, platelet surface activated GPIIb-IIIa expression, as reflected by mAb PAC1 binding, was, as expected, markedly increased compared with unstimulated samples (Figure 2A). R-138727 treatment caused a substantial reduction in the level of surface activated GPIIb-IIIa. The presence of either GPIIb-IIIa antagonist significantly reduced PAC1 binding to activated GPIIb-IIIa in collagen plus ADP-stimulated samples (Figure 2A). PAC1 binding was further inhibited when R-138727 was added to abciximab- or epitifibatide-treated samples, and combined GPIIb-IIIa and P2Y12 antagonism resulted in significant inhibition beyond R-138727 treatment alone (Figure 2A). In unstimulated (no agonist) samples with low baseline activated GPIIb-IIIa, PAC1 binding was reduced by either GPIIb-IIIa inhibitor and, more significantly, inhibited by the combination of R-138727 plus abciximab or epitifibatide (Figure 2A).

Table. Statistical analysis of platelet activation, aggregation, and procoagulant responses to ADP 20 μmol/L and collagen 20 μg/mL in the presence of R-138727 5 μmol/L, abciximab 3 μg/mL, or epitifibatide 0.9 μg/mL, and combinations thereof

Combined Platelet P2Y12 and GPIIb-IIIa Inhibition

To further assess the level of platelet activation with combined P2Y12 and GPIIb-IIIa inhibition, we evaluated the platelet surface expression of P-selectin. Two-factor RM-ANOVA of collagen plus ADP–stimulated platelet surface P-selectin (Table) showed a significant effect of R-138727 (P=0.0012), the GPIIb-IIIa antagonists (P=0.0131), and a significant interaction between R-138727 and the GPIIb-IIIa antagonists (P=0.0011). Individual treatment with R-138727 or abciximab reduced annexin V binding in collagen plus ADP–stimulated samples (annexin V–positive platelets 22.9±2.7% with vehicle versus 9.5±1.6% for R-138727, P=0.0004, and 14.7±1.9% for abciximab, P=0.0004), but no significant effect was observed with eptifibatide (P=0.0247 versus vehicle; nonsignificant with Bonferroni correction). No further inhibi-

**Monocyte–Platelet Aggregates**

As an additional marker of the level of platelet activation with combined P2Y12 and GPIIb-IIIa inhibition, monocyte–platelet aggregates were measured with and without collagen plus ADP stimulation. In the absence of antiplatelet agents, as expected, collagen plus ADP increased the percentage of monocytes bound to platelets (Figure 3A and 3B). By 2-factor RM-ANOVA, R-138727, GPIIb-IIIa antagonists, and the interaction between R-138727 and GPIIb-IIIa antagonists were highly significant for the collagen plus ADP–stimulated percentage of monocyte–platelet aggregates and the platelet fluorescence in monocyte–platelet aggregates (Table). In collagen plus ADP–stimulated samples, R-138727 reduced the percentage of monocyte–platelet aggregates and the level of platelet fluorescence in the aggregates, indicating a reduced number of platelets in the aggregates (Figure 3). Although abciximab and eptifibatide each resulted in numerical increases in the percentage of monocyte–platelet aggregates and platelet fluorescence in monocyte–platelet aggregates, in posttests, only the abciximab-induced increase in platelet fluorescence remained statistically significant. Addition of R-138727 to abciximab abrogated this increase, reducing platelet fluorescence in monocyte–platelet aggregates to the level observed with R-138727 treatment alone (Figure 3).

**Platelet Surface Expression of Phosphatidylserine**

In addition to their role in aggregate formation, activated platelets promote coagulation through surface exposure of procoagulant phosphatidylserine.17 As expected, stimulation with collagen plus ADP increased the percentage of annexin V–positive platelets (Figure 4). Two-factor RM-ANOVA analysis (Table) showed a significant effect of both R-138727 (P=0.0010) and the GPIIb-IIIa antagonists (P=0.0001) and a significant interaction between R-138727 and the GPIIb-IIIa antagonists (P<0.0001). Individual treatment with R-138727 or abciximab reduced annexin V binding in collagen plus ADP–stimulated samples (annexin V–positive platelets 22.9±2.7% with vehicle versus 9.5±1.6% for R-138727, P=0.0004, and 14.7±1.9% for abciximab, P=0.0004), but no significant effect was observed with eptifibatide (P=0.0247 versus vehicle; nonsignificant with Bonferroni correction). No further inhibi-
Tissue Factor Expression on Monocyte–Platelet Aggregates and Individual Platelets

Beyond platelet surface expression of phosphatidylserine, platelets and monocyte–platelet aggregates can stimulate coagulation through surface expression of tissue factor. In previous studies, treatment with R-138727 decreased the level of tissue factor on monocyte–platelet aggregates. To extend these studies, we investigated the effect of R-138727 combined with abciximab or eptifibatide on procoagulant surface expression of tissue factor. Stimulation with collagen plus ADP increased the level of tissue factor fluorescence on both monocyte–platelet aggregates and single platelets (Figure 5A and 5B). Two-factor RM-ANOVA analysis of tissue factor on monocyte–platelet aggregates (Table) showed significant effects of R-138727 (P<0.0007), GPIIb-IIIa antagonists (P<0.0001), and the interaction between R-138727 and GPIIb-IIIa antagonists (P=0.0001). Tissue factor on monocyte–platelet aggregates induced by collagen plus ADP was reduced by R-138727 (Figure 5A). In parallel to the increase in monocyte–platelet aggregates observed with abciximab or eptifibatide (Figure 3), individual treatment with either GPIIb-IIIa antagonist caused an increase in monocyte–platelet tissue factor (Figure 5A). The addition of R-138727 to abciximab or eptifibatide reduced tissue factor levels on monocyte–platelet aggregates. When tissue factor on individual platelets stimulated with collagen plus ADP was examined, R-138727 treatment caused significant inhibition, while the GPIIb-IIIa antagonists had no significant effect (2-factor RM-ANOVA R-138727, P<0.0001; GPIIb-IIIa antagonists, P=0.2341; Table) on platelet tissue factor (Figure 5B).

Platelet-Dependent Coagulation Factor Activation: F1.2 Generation and FXIIIa Activity

To determine the effects of combined platelet P2Y12 and GPIIb-IIIa inhibition on coagulation, we investigated platelet-dependent enhancement of thrombin generation and activation of
FXIII in the presence of R-138727 plus abciximab or eptifibatide. When thrombin generation was measured by the formation of F1.2 in whole blood, addition of collagen plus ADP, in the presence of priming concentrations of FVa and FXa, caused a marked increase in F1.2 compared with blood primed with FVa and FXa but without the addition of collagen plus ADP (Figure 6). Two-factor RM-ANOVA (Table) showed a significant effect of R-138727 (P=0.0002) and the GPIIb-IIIa antagonists (P=0.0102) and a significant interaction between R-138727 and the GPIIb-IIIa antagonists (P=0.0183). Collagen plus ADP–enhanced F1.2 levels were reduced by 38% by R-138727 treatment compared with vehicle (P=0.0064, 1-sample t test, Figure 6). Treatment with abciximab alone reduced the collagen plus ADP–dependent increase in F1.2 (P=0.0250, 1-sample t test), while eptifibatide treatment enhanced collagen plus ADP–stimulated F1.2 (P=0.0482, 1-sample t test), although neither effect reached statistical significance after Bonferroni correction. The combination of R-138727 plus abciximab or eptifibatide reduced F1.2 compared with individual GPIIb-IIIa antagonist treatment and resulted in a level of F1.2 that was comparable to R-138727 treatment alone (Figure 6).

FXIII generation, primed by addition of FVa and FXa, was significantly increased by platelet activation with collagen plus ADP (Figure 7). Relative FXIII activity in collagen plus ADP–activated samples was not significantly affected by treatment with R-138727 or eptifibatide alone (Figure 7). However, the relative FXIII activity was significantly, albeit modestly, decreased in the presence of abciximab (P=0.0015, 1-sample t test, Figure 7).

Discussion

The main findings of this study are as follows. (1) The combination of P2Y₁₂ and GPIIb-IIIa antagonists, at whole blood concentrations that demonstrate pharmacological
Combined Platelet P2Y₁₂ and GPIIb-Ⅲa Inhibition

Figure 7. Platelet-dependent FXIIIa generation in the presence of R-138727 plus abciximab or eptifibatide. Sodium citrate–anticoagulated blood was incubated with solution of CaCl₂, GPRP (to inhibit fibrin polymerization), FXa 60 pmol/L, and FVa 30 pmol/L combined with collagen 20 μg/mL plus ADP 20 μmol/L or no agonist. FXIIIa generation was monitored by the cleavage of a fluorogenic FXIIIa substrate, and the relative FXIIIa activity was reported as the reciprocal of the time to reach Vₘₐₓ, normalized per subject by the value obtained for a vehicle-treated sample stimulated with collagen plus ADP. Results are mean±SEM, from 6 experiments. *P<0.0071 vs no R-138727, vehicle treatment; †P<0.0071 vs corresponding treatment in the absence of R-138727; ‡P<0.0071 vs R-138727, vehicle treatment. GPRP indicates Gly-Pro-Arg-Pro; FVa and FXa, coagulation factors Va and Xa, respectively; Vₘₐₓ, maximum velocity.

Augmented Inhibition of Platelet Activation, Aggregation, and Procoagulant Activities by Combined Use of R-138727 and GPIIb-Ⅲa Antagonists

Because light transmission platelet aggregation has been the de facto gold standard for platelet function testing throughout the development of the GPIIb-Ⅲa antagonists and newer P2Y₁₂ antagonists, the additive inhibitory effect of R-138727 plus abciximab or eptifibatide on collagen– and ADP–stimulated platelet aggregation is not surprising. The additional inhibition of platelet aggregation and platelet surface activated GPIIb-Ⅲa expression by combined P2Y₁₂ and GPIIb-Ⅲa antagonists may in part explain the clinical benefit resulting from their combined use in the meta-analysis described earlier. Downstream effects of combined inhibition with abciximab and R-138727 observed in the present study [reduced annexin V–positive platelets (Figure 4) and reduced conversion of prothrombin to thrombin with concomitant release of F1.2 (Figure 6)] are also likely to be mechanistically linked to the clinical benefit observed in the meta-analysis. The results of the present study are similar to that reported for the combination of cangrelor, a reversible P2Y₁₂ antagonist and abciximab or tirofiban, which resulted in additive inhibition of platelet aggregate formation, dense granule secretion, soluble CD40 ligand release, annexin V binding, and procoagulant microparticle formation, and to a study of in vivo clopidogrel plus in vitro GPIIb-Ⅲa inhibition that demonstrated additive
inhibition of ADP- or collagen-induced platelet aggregation and fibrinogen binding to GPIIb-IIIa.\textsuperscript{20,21}

Enhanced Procoagulant Status Following Treatment With GPIIb-IIIa Antagonists Alone, and Ablation by R-138727

The results of previous studies on the effect of GPIIb-IIIa inhibitors on monocyte–platelet aggregate formation and tissue factor on monocyte–platelet aggregates are inconsistent, with GPIIb-IIIa inhibitors reported to both augment and inhibit these processes.\textsuperscript{22–25} In agreement with the present results, separate studies have shown that abciximab enhanced ADP-induced platelet fluorescence in monocyte–platelet aggregates,\textsuperscript{22} and eptifibatide enhanced tissue factor expression on monocytes.\textsuperscript{23} The enhanced procoagulant status observed after GPIIb-IIIa antagonist treatment may be relevant to the increased thrombotic complications observed with oral GPIIb-IIIa antagonists.\textsuperscript{26} In the current study, whole blood stimulated with collagen plus ADP in the presence of either abciximab or eptifibatide appears to be in a procoagulant state, as evidenced by increased exposure of tissue factor antigen on monocyte–platelet aggregates (Figure 5A), together with an increase in platelet mass associated with each monocyte (Figure 3B). Indeed, platelet activation–dependent prothrombinase activity is modestly enhanced in the presence of eptifibatide (Figure 6). However, abciximab under the same conditions reduced prothrombinase activity (Figure 6), thus demonstrating a difference in the ability of eptifibatide (a 1000 Da, small molecule, reversible GPIIb-IIIa antagonist) and abciximab (a much larger [50 000 Da], tight-binding GPIIb-IIIa antagonist) to modulate platelet-dependent procoagulant activity.

Prothrombin has been shown to bind to GPIIb-IIIa and this binding accelerates thrombin generation.\textsuperscript{27} With its larger size, abciximab (and other antibody inhibitors) may not only block prothrombin binding to GPIIb-IIIa but may also sterically hinder other binding reactions on the platelet surface that are important for thrombin generation, such as coagulation factor binding to surface-exposed phosphatidylinerine. This concept is in agreement with a previous study, showing that abciximab more strongly inhibited annexin V and factor V/Va binding to the platelet surface than eptifibatide.\textsuperscript{28} The molecular size difference and specific molecular interactions between each antagonist and GPIIb-IIIa may explain the variable response in prothrombin activation. Because tissue factor activation is modulated by protein disulfide-isomerase,\textsuperscript{29} it is also tempting to speculate that eptifibatide and abciximab differentially affect this activation.

In the present study, the addition of R-138727 to GPIIb-IIIa antagonists resulted in a significant decrease compared with GPIIb-IIIa inhibitors alone in the percentage of monocyte–platelet aggregates, tissue factor expression on monocyte–platelet aggregates, and thrombin generation. This is in agreement with a previous study on clopidogrel and abciximab which reported that the addition of clopidogrel to abciximab treatment ablated the abciximab-induced increase in monocyte–platelet aggregates.\textsuperscript{22} Taken together, the presently-described ablation by prasugrel’s active metabolite of the GPIIb-IIIa antagonist-induced increase of tissue factor on monocyte–platelet aggregates and the eptifibatide-induced increase in thrombin generation, suggests that inhibition of the platelet P2Y\textsubscript{12} ADP receptor may reduce the prothrombotic effects of GPIIb-IIIa antagonists.

Study Limitations and Strengths

This study used blood from healthy subjects rather than from acute coronary syndrome patients, the population for whom these drugs have an FDA-approved indication, to minimize the variables of comedinations and the degree of disease. However, all healthy donors were treated with aspirin to correspond to the clinical conditions where prasugrel and GPIIb-IIIa antagonists might be coadministered. The power to detect treatment differences is limited by the small sample size (n=6); however, significant effects of GPIIb-IIIa and/or P2Y\textsubscript{12} inhibition were detected for each end point, even after application of the conservative Bonferroni correction.

Conclusions

The presently described complementary effects of abciximab and prasugrel’s active metabolite on collagen plus ADP–induced platelet activation, aggregation, and procoagulant activity suggest that the combined use of abciximab and prasugrel may, to a greater degree than with either agent alone, reduce and destabilize thrombus formation in vivo. The GPIIb-IIIa antagonist-induced increase of tissue factor on monocyte–platelet aggregates and the eptifibatide-induced increase in thrombin generation were attenuated by prasugrel’s active metabolite, suggesting a novel mechanism for reducing the prothrombotic effects of these GPIIb-IIIa antagonists.

Sources of Funding

This study was supported in part by a grant from Eli Lilly and Daiichi Sankyo. Dr. Berny-Lang was supported by an NIH T32 Training Grant (5T32HL007574-31). This work was conducted...
Combined Platelet P2Y12 and GPIIb-IIIa Inhibition

Disclosures

Drs. Berny-Lang and Barnard report no conflicts. Dr. Jakubowski is an employee and shareholder of Eli Lilly and Company. Dr. Sugidachi is an employee of Daiichi Sankyo Co., Ltd. Dr. Michelson received research grants from GLSynthesis and Lilly/Daichi Sankyo; and is a member of a data monitoring committee for clinical trials of prasugrel sponsored by Lilly/Daichi Sankyo. Dr. Frelinger III received research grants from GLSynthesis and Lilly/Daichi Sankyo and is a consultant for Eli Lilly.
