Abstract

Increased expression of the aquaporin NtAQP1, which is known to function as a plasmalemma channel for CO2 and water, increases the rate of both photosynthesis and transpiration. In contrast, increased expression of Arabidopsis hexokinase1 (AtHXK1), a dual-function enzyme that mediates sugar sensing, decreases the expression of photosynthetic genes and the rate of transpiration and inhibits growth. Here, we show that AtHXK1 also decreases root and stem hydraulic conductivity and leaf mesophyll CO2 conductance (g_m). Due to their opposite effects on plant development and physiology, we examined the relationship between NtAQP1 and AtHXK1 at the whole-plant level using transgenic tomato plants expressing both genes simultaneously. NtAQP1 significantly improved growth and increased the transpiration rates of AtHXK1-expressing plants. Reciprocal grafting experiments indicated that this complementation occurs when both genes are expressed simultaneously in the shoot. Yet, NtAQP1 had only a marginal effect on the hydraulic conductivity of the double-transgenic plants, suggesting that the complementary effect of NtAQP1 is unrelated to shoot water transport. Rather, NtAQP1 significantly increased leaf mesophyll CO2 conductance and enhanced the rate of photosynthesis, suggesting that NtAQP1 facilitated the growth of the double-transgenic plants by enhancing mesophyll conductance of CO2.

Introduction

Aquaporins (AQP), also known as MIPs (major intrinsic proteins), are integral membrane proteins that increase the permeability of membranes to water, as well as small uncharged molecules [1]. Of all kingdoms, the plant kingdom contains the largest known AQP family consisting over 30 members [2,3]. There are 35 AQPs in Arabidopsis (Arabidopsis thaliana [4]), 36 in maize (Zea mays [1]) and 37 in tomato (Solanum lycopersicum [5]). Based on sequence similarities, AQP have been divided into five subgroups: plasma membrane intrinsic proteins (PIPs), tonoplast intrinsic proteins (TIPs), NOD26-like intrinsic proteins (NIPs), small basic intrinsic proteins (SIPs) and X intrinsic proteins (XIP) [4,6]. Plant PIPs can be divided into two major groups, PIP1 and PIP2, on the basis of their sequences and water-channel activity. PIP2 proteins exhibit high levels of water-channel activity in Xenopus oocytes and yeast vesicles; whereas PIP1 proteins often have relatively low permeability to water [7–12].

Evidence for the role of PIP1 aquaporin in planta has come from mutant analyses and the manipulation of PIP1 expression in plants. Analysis of Arabidopsis mutants has shown that AtPIP1,2 can account for a significant portion of aquaporin-mediated leaf water transport [13]. The antisense expression of AtPIP1,2 in Arabidopsis has been associated with reductions in the membrane hydraulic conductivity of isolated protoplasts and decreased total root hydraulic conductivity [14,15]. Antisense suppression of NtAQP1 (a member of the PIP1 subgroup) in tobacco (Nicotiana tabacum) lowered the level of expression of several PIP1 homologues and resulted in a significant decrease in protoplast membrane water permeability, reduced root hydraulic conductivity and decreased transpiration [16,17].

The results of heterologous expression in Xenopus oocytes suggest that, in addition to functioning as a water channel, NtAQP1 is also a membrane CO2 pore that facilitates the transport of CO2 across membranes [7,18]. The movement of CO2 between the substomatal cavities and the sites of carboxylation within chloroplasts, through plasma and chloroplast membranes, is generally termed leaf mesophyll conductance (g_m) [19]. The ability of NtAQP1 and its Arabidopsis homolog AtPIP1,2 to function as CO2 membrane transport facilitators has been demonstrated in in vivo experiments. Increased expression of NtAQP1 in tobacco plants enhanced CO2 incorporation and stomatal conductance; whereas antisense suppression of NtAQP1 had the opposite effect [18]. In other...
studies, overexpression of \textit{AtPIP1,2} or \textit{NaAQP1} in tobacco plants significantly enhanced the rates of growth, transpiration and photosynthesis [20–22]; whereas antisense suppression of \textit{NaAQP1} in tobacco plants and T-DNA insertion Arabidopsis mutants in \textit{AtPIP1,2} reduced \textit{gm} and led to lower rates of photosynthesis [21,23,24].

Unlike \textit{NaAQP1}, overexpression of Arabidopsis hexokinase \textit{(AHXK3)} in Arabidopsis and tomato plants decreased photosynthesis, transpiration, and growth [25,26]. \textit{AhHXK1} is a sugar-sensing enzyme that monitors glucose levels, most likely in mesophyll cells of photosynthetic tissues. When glucose levels are sufficiently high, this enzyme inhibits the expression of photosynthetic genes, decreases chlorophyll levels and reduces the rate of photosynthesis [25–29]. In addition, \textit{AhHXK1} also stimulates stomatal closure and decreases transpiration in response to increasing sugar levels [26,30]. In light of the opposite effects of \textit{AhHXK1} and \textit{NaAQP1} on photosynthesis and growth, we examined the relationship between \textit{AhHXK1} and \textit{NaAQP1} using double-transgenic plants that express \textit{AhHXK1} and \textit{NaAQP1} simultaneously. We found that \textit{NaAQP1} significantly compensated for the growth inhibition imposed by \textit{AhHXK1}, primarily by enhancing mesophyll \textit{CO}_2 conductance and the rate of photosynthesis, while the hydraulic conductivity in those plants remained unchanged.

Materials and Methods

Construction of transgenic AQP1 plants

Cloning of the full-length cDNA of the tobacco \textit{(Nicocons tabacum)} \textit{NaAQP1} under the control of the 35S constitutive promoter was performed as described in [22]. MP-1 lines (\textit{Solanum lycopersicum} cv. MP-1) were transformed using the \textit{Agrobacterium tumefaciens} transformation method [31]. Plants were assayed for the presence of \textit{NaAQP1} by PCR using the following primers: 35Sprom-Fwd: TATCTCTTCGCAAGACCCTCC, and NtAQP1-Rev: TGCC-TGGTCTGTGGTTAGAT.

Plant material

All experiments were conducted with wild-type (WT) tomato (\textit{Solanum lycopersicum} cv. MP-1), isogenic independent transgenic homozygous tomato lines expressing different levels of the Arabidopsis \textit{AHXK3} (HK37, HK4 and HK38 lines), as previously described in Dai [25], and an isogenic \textit{NaAQP1}-expressing transgenic homozygous line \textit{AQP1}. Double-transgenic homozygous plants \textit{NtAQP1xAhHXK1} (\textit{AQP1xHK4}) were generated by crossing the \textit{AQP1} and HK4 parental lines. After self-pollination of the F1 hybrid plants, screening for F2 plants homozygous for both genes was performed using the highly sensitive Taq-Man DNA quantitative PCR method with specific probes, as described by German et al. [32]. Further validation of homozygosity was carried out by PCR analysis of tens of F3 plants using specific primers for \textit{NaAQP1} (35Sprom-Fwd:TATCTCTTCGCAAGACCTCC, \textit{NaAQP1}-Rev: TGGCTCTTCCTGCTGTGTATGAT) and \textit{AhHXK1} (Fwd:CGGGAAGCAGAGGGTTT, Rev:TATGATGATGCTGTATGAT).

Measurements of root hydraulic conductance

The hydraulic conductance of the tomato root system (\textit{L}_r) was assessed using plants grown hydroponically and was determined by measuring the flow induced in response to 1 bar of applied pressure. De-topped root systems were fitted with a plastic tube filled with deionized water and connected to a beaker located on a balance (\textit{Sartorius} \textit{\pm 0.01 mg}). The root system was sealed in a chamber containing the hydroponic solution in which the plants had been grown. The pressure in the chamber was regulated using a needle valve, which was adjusted to allow a small leak into the chamber, so that the air used to pressurize the chamber also served to aerate the medium. Water flow through the root system was automatically recorded by a computer at 30 s intervals. At the end of each experiment, the roots were dried in an oven for 72 h at 90°C and the dry weight of the root system was then measured.

Measurements of stem hydraulic conductivity

Stem hydraulic conductivity was assessed on five to seven stems of each genotype. Short sections of stems (∼2–3 cm long) were cut under water directly from the intact plants to prevent embolisms caused by air entering into the cut vessels. Stems were connected to a balance (\textit{Sartorius} \textit{\pm 0.1 mg}) by a plastic tube and a filtered 10 mM KCl solution, used as a perfusion solution, was located on the balance in a beaker. Stem segments were then perfused under elevated pressure (0.2 MPa) to remove any embolisms and hydraulic conductivity (\textit{K}) was then calculated as the flow rate multiplied by the length of the stem segment and divided by the pressure gradient.

Xylem cross-sectional area was microscopically determined for each stem to allow the calculation of the xylem-specific stem conductivity (\textit{K}_{sx}, which equals \textit{K} divided by total xylem area). Free-hand cross-sections were excised and stained for a few seconds in a diluted Safranin solution. The sections were then rinsed in deionized water for few minutes and photographed under a compound microscope. Xylem area was later determined using the ImageJ software (\textit{http://rsweb.nih.gov/ij/}).

Measurements of whole-plant transpiration

Whole-plant transpiration rates and relative daily transpiration (RDT) were determined using lysimeters, as described in detail by Sadle et al. [22]. WT, \textit{AQP1}, HK4, \textit{AQP1xHK4} and grafted plants were planted in 3.9-L pots and grown under controlled conditions. Each pot was placed on a temperature-compensated load cell with digital output and was sealed to prevent evaporation from the surface of the growth medium. A wet, vertical wick made of 0.14 m² cotton fibers partially submerged in a 1-L water tank was placed on a similar load cell and used as a reference for the temporal variations in the potential transpiration rate. The output of the load cells was monitored every 10 s and the average readings over 3-min intervals were logged in a data logger for further analysis. The whole-plant transpiration rate was calculated as a numerical derivative of the load cell output following a data-smoothing process [22]. The plant’s daily transpiration rate was normalized to the total leaf area [measured using a LI-COR area meter, model LI-3100: (Lincoln, Nebraska, USA)] or to total plant weight, and to the data for neighboring submerged wick. These figures were averaged for each line and graft type (amount taken up by the wick daily \textit{\pm 100%}).

Protein extraction and analysis of hexokinase activity

Protein extraction and hexokinase activity measurements were performed as described by Dai et al. [25].

RNA extraction, cDNA preparation and quantitative real-time PCR

Leaf tissue was harvested from WT, \textit{AQP1}, HK4 and \textit{AQP1xHK4} plants and total RNA was extracted from that tissue using EZ-RNA kit (Biological Industries Co., Beit Haemek, Israel) according to the manufacturer’s protocol. The RNA was treated with DNase (Ambion, Austin, TX, USA), according to the manufacturer’s instructions, to degrade any residual DNA. The presence of RNA was confirmed by gel electrophoresis and DNA
degradation was confirmed by PCR. For cDNA preparation, total RNA (1 μg) was taken for reverse transcription-PCR using MMLV RT (Promega, Madison, WI, USA) in a 25-μl reaction with 2 μl of random primers (Promega, Madison, WI, USA) and 1 μl of mixed poly-dT primers. cDNA samples were diluted 1:7 in RNase-free DEPC (Diethylpyrocarbonate) water. Quantitative real-time PCR reactions were performed using SYBR Green mix (Thermo-Scientific, Waltham, Massachusetts, USA). Reactions were run in a RotorGene 6000 cycler (Corbett, Mortlake, New South Wales, Australia). Following an initial pre-heating step at 95°C for 15 min, there were 40 cycles of amplification consisting of 10 s at 95°C, 15 s at 55°C, 10 s at 60°C and 20 s at 72°C.

Results

AtHXK1 decreases root and stem hydraulic conductivity

To examine the effects of AtHXK1 on hydraulic proprieties, we measured the root conductance and stem hydraulic conductivity of tomato lines expressing elevated levels of AtHXK1 (Fig. 1). HK37, HK4 and HK38 are very well characterized independent isogenic transgenic tomato lines that express AtHXK1 at different levels [25]. These lines exhibit HKX activity that is about 2, 5 and 6 times higher than that of WT plants, respectively [25]. The root hydraulic conductance ($L_r$) and xylem-specific stem hydraulic conductivity ($K_w$) of HK4 and HK38 lines with high levels of AtHXK1 expression were significantly lower than those of WT plants (Fig. 1A and 1B).

NtAQP1 complements AtHXK1-mediated growth inhibition

While AtHXK1 decreases hydraulic conductivity, photosynthesis and growth [25,26], NtAQP1 increases hydraulic conductivity and enhances photosynthesis and growth [20,22]. In light of these opposite effects of AtHXK1 and NtAQP1, we were interested in

\[ L_{\text{RI}} = \frac{C_{\text{RI}}}{F_{\text{RI}}} \]

\[ F_{\text{RI}} = \frac{F_{m} - F_{\text{RI}}}{J_{\text{RI}}} \]

\[ J_{\text{RI}} = \text{Photosynthetically active photon flux density (PPFD), } x \beta \]

\[ J_{\text{RI}} = \frac{F_{m} - F_{\text{RI}}}{J_{\text{RI}}} \]

Figure 1. AtHXK1 decreases root hydraulic conductance and stem hydraulic conductivity. Root conductance (A) and xylem-specific stem hydraulic conductivity (B) were determined for control (WT) and transgenic plants expressing different levels of AtHXK1 (AtHXK1 expression from moderate to high: HK37<KHK4<KHK38; [25]). Data are means ± SE (n=6 for $L_r$, n=5 for $K_w$). Different letters indicate a significant difference (t test, P<0.05). doi:10.1371/journal.pone.0087888.g001
exploring the relationship between \textit{NaAQP1} and \textit{AtHXK1} at the whole-plant level. To that end, we developed tomato line expressing \textit{NaAQP1} against the same genetic background (MPl [31]) as that of the HK lines and assigned it AQ\text{PI}. Expression of the \textit{NaAQP1} gene and the level of \textit{NaAQP1} protein were determined by quantitative PCR and Western blot analysis, respectively (Fig. S1). We then created double-transgenic plants expressing both \textit{AtHXK1} and \textit{NaAQP1} simultaneously by crossing AQ\text{PI} lines with the HK4 line. Plants homozygous for both genes were identified and are referred to as AQ\text{PI}xHK4.

AQ\text{PI}xHK4 plants were taller and had more leaf area than the HK4 parent line (Fig. 2), suggesting that \textit{NaAQP1} complemented the growth-inhibition effects of \textit{AtHXK1}. To verify that this complementation effect was not the result of lowered expression of \textit{AtHXK1}, HXK activity and the sugar-sensing effects of HXK were checked. HXK activity in the double-transgenic plants was similar to that of the HK4 parent plants, about 7-fold higher than that of the control WT and the AQ\text{PI} (homozygote) parent plants (Fig. 2D). We also examined the effect of HXK on the expression of the well-established sugar-sensing photosynthesis marker gene \textit{CAB1}, which is known to be repressed by \textit{AtHXK1} [26,27,29]. \textit{CAB1} expression in AQ\text{PI}xHK4 was repressed to levels similar to those observed in the HK4 plants (Fig. 2E), indicating that \textit{AtHXK1} mediated sugar-sensing effects in the double-transgenic plants. These results suggest that the growth complementation effects of \textit{NaAQP1} do not stem from suppression of HXK activity, but rather are probably due to epistatic physiological effects of \textit{NaAQP1}.

\textbf{Growth complementation of AQ\text{PI}xHXK is related to \textit{NaAQP1} copy number}

The epistatic effects of \textit{NaAQP1} on plant growth were observed primarily in plants homozygous for both genes, \textit{NaAQP1} and \textit{AtHXK1} (Fig. 3). Crossing AQ\text{PI}xHK4 with WT, HK4 or AQ\text{PI} lines yielded plants that were heterozygous or homozygous for \textit{NaAQP1}, \textit{AtHXK1} or both genes. Only plants that were homozygous for \textit{AtHXK1} exhibited significant growth inhibition, and \textit{NaAQP1} enhanced the growth of \textit{AtHXK1} homozygous plants only when present in the homozygous state (Fig. 3). Plants that were heterozygous for \textit{NaAQP1} and lacked \textit{AtHXK1} displayed slightly improved growth, but that effect was abolished in the presence of one or two copies of \textit{AtHXK1}, suggesting a dosage effect in the relationship between \textit{NaAQP1} and \textit{AtHXK1}.

\textbf{\textit{NaAQP1} enhances the stomatal conductance and transpiration of \textit{AtHXK1} plants}

In previous studies, overexpression of \textit{AtHXK1} decreased stomatal conductance and transpiration; whereas overexpression of \textit{NaAQP1} increased stomatal conductance and transpiration [18,20–22,26,30]. Therefore, we tested the combined effects of \textit{AtHXK1} and \textit{NaAQP1} on stomatal conductance and transpiration. Stomatal conductance (g) of HK4 plants was significantly lower than that of WT plants (Table 1; [30]). Meanwhile, the g of the double-transgenic plants was similar to that of the WT plants (Table 1). Continuous measurements of whole-plant transpiration per unit leaf area over the course of the day revealed significantly lower transpiration rates in HK4 plants, as compared to WT and AQ\text{PI} plants (Fig. 4). Yet, the double-transgenic plants had intermediate-level transpiration rates that were higher than those of HK4 plants (Fig. 4). These results indicate that \textit{NaAQP1} enhanced stomatal conductance and compensated for the limitations imposed on transpiration rates by \textit{AtHXK1}.

\textbf{Figure 2. \textit{NaAQP1} complements growth inhibition of \textit{AtHXK1}. (A)} Representative images of 5-week-old tomato plants homozygous for \textit{NaAQP1} (AQ\text{PI}), \textit{AtHXK1} (HK4) or both genes (AQ\text{PI}xHK4). (B) Height (n=8) and (C) leaf area (n=6) of 9-week-old plants. (D) Hexokinase activity was determined using protein extracted from mature leaves of WT, AQ\text{PI}, HK4 and AQ\text{PI}xHK4 plants. doi:10.1371/journal.pone.0008788.g002

\textbf{Growth and transpiration complementation occurs when \textit{NaAQP1} and \textit{AtHXK1} are simultaneously expressed in the shoot}

To examine whether the decreased transpiration and growth imposed by \textit{AtHXK1} and its complementation by \textit{NaAQP1} emanate from distinct effects on roots or shoots, we created reciprocal grafts, in which WT, AQ\text{PI} and HK4 shoots were grafted onto WT, AQ\text{PI} and HK4 roots, covering all nine possible combinations. (Five combinations involving AQ\text{PI} are shown in Figure 5A and the other four combinations are shown in Figure 2A of [30]). \textit{AtHXK1} inhibited growth only when expressed in shoots, independent of the root genotype (Fig. 5A and [30]). Similarly, measurements of cumulative whole-plant relative daily transpiration of the grafted plants indicated that \textit{AtHXK1} decreased transpiration by about 50% only when expressed in shoots.
independent of the root genotype [Fig. 5B], in line with our recent discovery that \( \text{AtHXK1} \) stimulates stomatal closure and reduces transpiration when expressed in shoots [30]. i.e., \( \text{NtAQP1} \) in roots had no complementation effect on \( \text{HK4} \) shoots) (Fig. 5A). These results show that separate expression of \( \text{NtAQP1} \) and \( \text{AtHXK1} \) in roots or shoots is insufficient to achieve complementation of \( \text{AtHXK1} \) phenotypes by \( \text{NtAQP1} \) and that the complementation of \( \text{AtHXK1} \) effects by \( \text{NtAQP1} \) occurs only when both genes are expressed simultaneously in the shoots. \( \text{NtAQP1} \) does not improve hydraulic conductance of \( \text{AtHXK1} \) plants, but does increase the conductance of CO2 in the leaf mesophyll and the rate of photosynthesis. The enhanced transpiration of the double-transgenic plants relative to \( \text{HK4} \) plants might suggest that \( \text{NtAQP1} \) could potentially improve the low hydraulic properties of \( \text{HK4} \) plants. We, therefore, measured the root and stem hydraulic conductivity of the WT, \( \text{AQP1} \), \( \text{HK4} \) and double-transgenic plants. \( \text{NtAQP1} \) did not improve the root conductance or xylem-specific stem hydraulic conductivity \( (L_r \text{ and } K_{ss}) \) respectively of the double-transgenic plants, which remained low, as in the \( \text{HK4} \) plants (Table 1). However, gas-exchange analysis of the double-transgenic plants revealed that \( \text{NtAQP1} \) increased photosynthesis rates \( (A) \), CO2 conductance \( (g_m) \) and stomatal conductance \( (g_s) \), with no effect on intracellular CO2 concentration \( (C_i) \), as compared to the low \( A \), \( g_m \) and \( g_s \) values observed in the \( \text{HK4} \) plants (Table 1). In addition, \( \text{NtAQP1} \) increased both the concentration of CO2 in the chloroplasts \( (C_c) \) and the electron transport rate \( (J) \), as compared to the \( \text{HK4} \) plants (Table 1). We,
therefore, suggest that the complementation of \( \text{AtHXK1} \) effects by \( \text{NtAQP1} \) is primarily due to the role of \( \text{NtAQP1} \) as a CO2 facilitator, which enhances the conductance of CO2 in the mesophyll thereby elevating the rate of photosynthesis despite the low expression of \( \text{CAB1} \) in \( \text{AQP1xHK4} \) plants.

**Discussion**

\( \text{PIP1-AQPs} \) were shown to enhance cell permeability to both CO2 and water \([7,13,18]\). Overexpression of \( \text{NtAQP1} \) in tobacco plants enhanced leaf mesophyll CO2 conductance (\( g_m \)), hydraulic

conductivity, stomatal conductance ($g_s$), transpiration and photosynthesis ($A_k$) [18,20,21]. Expression of NtAQP1 in tomato plants also enhanced photosynthesis, stomatal conductance and transpiration [22]. However, in our study, NtAQP1 did not enhance photosynthesis, stomatal conductance or hydraulic conductivity relative to WT plants (Fig. 5, Table 1) and enhanced transpiration only slightly (Fig. 4). These differences may be due to the different tomato genotype used in our study (MP1-31, an indeterminate variety) or to different expression levels of NtAQP1. Nevertheless, photosynthesis, stomatal conductance and transpiration were elevated by NtAQP1 in the double-transgenic plants (AQP1xHK4), as compared to the HK4 parental (isogenic) line. Yet, the hydraulic conductivity of AQP1xHK4 remained low as in the HK4 plants, implying that the increased transpiration that was observed is not directly related to hydraulic characteristics. Rather, the increased transpiration is most likely due to high $g_s$ values in the mesophyll, which opens stomata and increases the influx of CO$_2$ to help maintain constant levels of $C_i$ in the substomatal cavity [44,45]. High levels of $A_k$, $g_s$, and $g_m$, accompanied by constant $C_i$, were also reported in previous studies of tobacco plants overexpressing NtAQP1 [18,21,42].

AtHXK1 is a sugar-sensing enzyme that inhibits the expression of photosynthetic genes, decreases chlorophyll levels and reduces the rate of photosynthesis in response to increasing sugar levels [25–29]. As a result, tomato and Arabidopsis plants with high levels of AtHXK1 expression display severe growth inhibition directly correlated to AtHXK1 expression and activity levels [25,26]. It is likely that part of the growth inhibition imposed by AtHXK1 is the result of insufficient photosynthesis, since the increased photosynthesis rate observed in AQP1xHK4 plants partially eliminated this growth inhibition.

The increased rate of photosynthesis observed in AQP1xHK4 plants, despite the low level of expression of the photosynthetic gene CAB1 in those plants, can probably be attributed to NtAQP1, which accelerates CO$_2$ mesophyll conductance ($g_m$) [21,22]. The CO$_2$ mesophyll conductance of HK4 plants is significantly lower than that of WT plants and is enhanced by simultaneous expression of NtAQP1, indicating that CO$_2$ mesophyll conductance significantly affects growth.

It appears that, in addition to its known sugar-sensing effect (reducing expression of photosynthetic genes and reducing the rate of photosynthesis [25–27,29,46]; Fig. 2E and Table 1), AtHXK1 also reduces $g_m$, perhaps by reducing the expression of TRAMP (Fig. S2), the tomato homolog of NtAQP1 [47]. Indeed, lower $g_m$ levels have been observed in tobacco NtAQP1 antisense lines [21] and Arabidopsis pop1;2 mutants (a CO$_2$-facilitating AQP) [24]. In those studies, the decrease in $g_m$ was accompanied by lower $C_i$. In agreement with the findings of those studies, the HK4 plants in our study exhibited lower $C_i$ than the WT plants and the expression of NtAQP1 in the double-transgenic plants (AQP1xHK4) led to full complementation of $C_i$ (Table 1). Interestingly, the HK4 plants had lower electron transport rates ($J$) than the WT plants, while a clear recovery was observed in the AQP1xHK4 plants (Table 1) despite the low level of expression of the photosynthetic gene CAB1 in the AQP1xHK4 plants (Fig. 2E).

It has previously been shown that expression level of NtAQP1 which affects $g_m$ levels also affects electron transport rates ($J$) [21,24,40]. Flexas et al. [21] hypothesized that modified intercellular CO$_2$ concentrations may trigger differences in leaf photosynthetic capacity, so that the photosynthetic machinery can adjust to the change in mesophyll conductance. This would also explain why $g_m$ usually scales with photosynthetic capacity, as has been observed in broad comparisons of different species [49,50].

The effect of AtHXK1 on $g_m$ suggests that HXK might coordinate photosynthesis with sugar levels by several mechanisms in different cell types. It inhibits expression of photosynthetic genes [25,46] and reduces $g_m$ most likely in mesophyll photosynthetic cells. In guard cells HXK mediates stomatal closure in response to sugars and reduces stomatal conductance ($g_s$) [26,30]. These findings support the existence of a multilevel feedback-inhibition mechanism that is mediated by HXK in response to sugars. When sugar levels are high, likely when the rate of photosynthesis exceeds the rate at which the sugar is loaded and carried by the phloem, the surplus of sugar is sensed by HXK in mesophyll and guard cells, which respond in concert to reduce both unnecessary investments in photosynthetic capacity and water loss. This response includes reducing the expression of photosynthetic genes, slowing chlorophyll production, diminishing mesophyll CO$_2$ conductance and closing the stomata.

In addition to these effects in shoots, HXK reduces the hydraulic conductivity of stem and roots via an as yet unknown mechanism. This reduction in hydraulic conductivity occurs independently of stomatal conductance, as it also happens in the double-transgenic plants that have WT levels of stomatal conductance (Table 1). Nevertheless, grafting experiments indicate that neither overexpression of AtHXK1 in roots nor expression of AtHXK1 in the stem has any visible physiological effects. Rather, overexpression of AtHXK1 in shoots is necessary and sufficient to obtain a photosynthesis effect and growth inhibition [25,30]. The dominant effect of AtHXK1, lowering hydraulic conductance in AQP1xHK4, might be the reason for the intermediate transpiration rate of AQP1xHK4 plants, which is lower than that of WT plants (Fig. 4), despite the increase in stomatal conductance to levels similar to that of WT plants (Table 1). It has been suggested that NtAQP1 might play independent roles in leaves and roots, a hydraulic role in roots and a membrane CO$_2$ permeability role in shoots [22]. The improved $g_m$ observed in the double-transgenic plants supports the notion that, in leaves, NtAQP1 functions as a CO$_2$ transmembrane facilitator and that the complementation effect of NtAQP1 may be primarily attributed to its affect on CO$_2$ conductance in leaf mesophyll. The roles of HXK and PIP1 in the regulation of photosynthesis, stomatal conductance and transpiration are well established [18,20–22,25–29]. This study suggests that HXK and PIP1 together may influence these central properties of plant physiology and, eventually, plant growth.

**Supporting Information**

**Figure S1 Expression analysis of NtAQP1 in AQP1 transgenic line:** Presence of NtAQP1 DNA, RNA and protein. (A) The presence of NtAQP1 was assayed by PCR using NtAQP1-specific primers; transgenic AQP1 plants yielded the expected 930-bp product. WT is a negative non-transformed wild-type plant. + stands for a positive PCR control with a plasmid containing NtAQP1. Ladder: 100-bp ladder. (B) cDNA of AQP1 was subjected to semi-quantitative PCR using NtAQP1-specific primers; Fwd-CCGGGGCGAGTTCAATCCCG, Rev-TGCGCTGTCTGTGGTCGAGACTAC. Amplification was performed using 35 PCR cycles. StIP (cyclinophilin – accession: M55019) was used as a control. (C) Western blot analysis of protein extracts from AQP1 plants probed with NtAQP1-specific antibody (upper panel); Ponceau red staining of the Western blot indicating equal protein loading (lower panel). Western blot analysis and Ponceau staining were performed exactly as described in Sade et al. [22].

Figure S2 Expression of the TRAMP is suppressed by AtHXK1. Expression level of TRAMP (tomato ripening associated membrane protein, accession no. NM_001247210), the tomato NaAQP1 homolog, was determined by quantitative realtime PCR using cDNA extracted from leaves of WT and HK4 plants. Data are means of five independent biological repeats ± SE. Different letters indicate a significant difference (t-test, P<0.05). SIG9P (cytoplasm) was used for normalization. (TIF)
