Abstract

The inflammasome regulates release of caspase activation-dependent cytokines, including IL-1β, IL-18, and high-mobility group box 1 (HMGB1)1-5. During the course of studying HMGB1 release mechanisms, we discovered an important role of double-stranded RNA dependent protein PKR.
kinase (PKR) in inflammasome activation. Exposure of macrophages to inflammasome agonists induced PKR autophosphorylation. PKR inactivation by genetic deletion or pharmacological inhibition severely impaired inflammasome activation in response to double-stranded RNA, ATP, monosodium urate, adjuvant aluminum, rotenone, live E. coli, anthrax lethal toxin, DNA transfection, and S. Typhimurium infection. PKR deficiency significantly inhibited the secretion of IL-1beta, IL-18 and HMGB1 in E. coli-induced peritonitis. PKR physically interacts with multiple inflammasome components, including NLR family pyrin domain-containing 3 (NLRP3), NLR family pyrin domain-containing 1 (NLRP1), NLR family CARD domain-containing protein 4 (NLRC4), Absent in melanoma 2 (AIM2), and broadly regulates inflammasome activation. PKR autophosphorylation in a cell free system with recombinant NLRP3, ASC and pro-caspase-1 reconstitutes inflammasome activity. These results reveal a critical role of PKR in inflammasome activation, and indicate that it should be possible to pharmacologically target this molecule to treat inflammation.

High-mobility group box 1 (HMGB1), a ubiquitous nuclear and cytosolic protein, is released into the extracellular space during sterile inflammation and infection. Immunocompetent cells secrete HMGB1 following stimulation with microbial products and other danger signals. Ischemic and injured somatic cells also release HMGB1, but in this case the release mechanisms are passive. Extracellular HMGB1 signals through TLR4 receptors in macrophages to induce cytokine release, and mediate cell migration by interacting with RAGE. The importance of these mechanisms in disease pathogenesis has been established, because neutralizing HMGB1 attenuates disease severity in arthritis, colitis, sepsis, ischemia reperfusion, and other infectious and sterile injury syndromes. The mediator role of HMGB1 at the intersection of both sterile and infectious inflammation highlights the importance of mechanisms that regulate the secretion of HMGB1 from immune cells.

Early observations suggested that secretion of HMGB1 from macrophages requires inflammasome and caspase activity, and is highly associated with HMGB1 translocation from nucleus to cytoplasm. HMGB1 is also a universal sentinel to viral invasion, and its release can be stimulated by Poly I:C, a double-stranded RNA (dsRNA) mimic. Interested in studying HMGB1 release mechanisms from macrophages exposed to Poly I:C, we first considered earlier observations that double-stranded RNA dependent kinase (PKR) is phosphorylated in these conditions. As PKR is also activated by prototypical PAMPs and DAMPs known to stimulate HMGB1 release, and activate the inflammasome, we reasoned that PKR activation might participate in inflammasome activation.

Accordingly, we measured HMGB1 release by peritoneal macrophages obtained from PKR-deficient (PKR−/−) mice, in which the PKR kinase domain had been functionally inactivated by genetic deletion. HMGB1 secretion following Poly I:C exposure in PKR−/− macrophages was significantly decreased as compared to wild-type (PKR+/+) macrophages (Fig. 1a). Pharmacological inhibition of PKR in PKR+/− macrophages dose-dependently, and significantly, inhibited Poly I:C-induced HMGB1 release and PKR phosphorylation (Fig. 1b, Supplementary Fig. 1). Other prototypical danger signals, including ATP, monosodium urate (MSU), adjuvant aluminum (ALU), and live E. coli also significantly
increased PKR phosphorylation and HMGB1 release (Fig. 1c-e). Addition of potassium to the extracellular space significantly inhibited ATP induced PKR activation (Fig. 1c). Inactivation of macrophage PKR by genetic deletion (Fig. 1d-e) or pharmacological inhibition (Fig. 1f, Supplementary Fig. 2) also significantly inhibited HMGB1 release.

Pyroptosis, a form of programmed, inflammatory cell death, occurs with macrophage inflammasome activation, and we observed that deletion of PKR significantly inhibited LDH release (Fig. 1g). Analysis by tandem mass spectrometry of HMGB1 released in response to ATP, MSU, or ALU indicated that HMGB1 was highly acetylated in the nuclear location sequence (NLS) (Fig. 1h, Supplementary Fig. 3-6). In contrast, HMGB1 released from macrophages subjected to freeze/thaw cycles was not acetylated in the NLS (Fig. 1h). Together with evidence that inflammasome activation participates in the nuclear translocation of HMGB1, these results indicated that HMGB1 hyperacetylation and release, and inflammasome activation, are regulated by PKR.

To address the role of PKR in activating the NLRP3 inflammasome, we measured caspase-1 activation and IL-1β cleavage in peritoneal macrophages from PKR+/+ and PKR−/− mice. Caspase-1 activation and IL-1β cleavage were significantly inhibited in PKR−/− macrophages stimulated by exposure to ATP, MSU and ALU (Fig. 2a). Similar results were obtained in bone-marrow-derived dendritic cells (Supplementary Fig. 7) and macrophages (Supplementary Fig. 8). The expression of NLRP3 and pro-IL-1β did not differ significantly in PKR−/− macrophages as compared to PKR+/+ macrophages (Fig. 2a, Supplementary Fig. 9), but IL-1β secretion by macrophages exposed to live E. coli was significantly inhibited in PKR−/− macrophages as compared to PKR+/+ macrophages (Fig. 2b). TNF release in the PKR+/+ and PKR−/− macrophages was comparable, indicating that the decreased release of IL-1β in the PKR−/− macrophages is not attributable to a global defect in signal transduction (Supplementary Fig. 10).

Transfection with Poly I:C and E. coli RNA in bone-marrow derived dendritic cells significantly activated caspase-1 and stimulated IL-1β cleavage in PKR+/+, but not PKR−/− cells (Supplementary Fig. 11). Similar observations were obtained in PKR−/− and PKR+/+ macrophages stimulated by rotenone, which induces mitochondrial ROS production and PKR phosphorylation (Supplementary Fig. 12, 13). Pharmacological inhibition of PKR dose-dependently suppressed MSU-induced caspase-1 activation and IL-1β cleavage. The observed IC50’s of 2-AP and C13H8N4OS were 0.5 mM and 0.25 μM respectively, which agree closely with their known IC50 against PKR (Fig. 2c, Supplementary Fig. 14). PKR inhibition significantly reduced ATP- and ALU-induced inflammasome activation in murine macrophages (Supplementary Fig. 15, 16), and in human monocytic THP-1 cells (Supplementary Fig. 17). IL-18 release was significantly decreased in PKR−/− macrophages as compared with PKR+/+ macrophages stimulated with ATP, MSU or ALU, whereas TNF and IL-6 were not suppressed (Supplementary Fig. 18). Addition of 2-AP reduced MSU-induced IL-18 release, but not TNF and IL-6 (Supplementary Fig. 18). 2-AP failed to inhibit MSU-induced caspase-1 activation and IL-1β cleavage in PKR−/− macrophages (Supplementary Fig. 19). Collectively, these findings establish a critical role for PKR in activating the NLRP3 inflammasome.
PKR<sup>+/+</sup> and PKR<sup>−/−</sup> mice were then exposed to live *E. coli*, in order to activate the NLRP3 inflammasome in vivo. Serum IL-1β, IL-18, and HMGB1 were significantly reduced in PKR<sup>−/−</sup> mice as compared to PKR<sup>+/+</sup> mice (Fig. 2d). In agreement with prior evidence suggesting that peritoneal neutrophil infiltration requires inflammasome activation, we observed significantly fewer neutrophils in peritoneal lavage from PKR<sup>−/−</sup> mice as compared to PKR<sup>+/+</sup> controls (Fig. 2e). Serum IL-6, an inflammasome independent cytokine, was comparable in both groups (Fig. 2d). Exposure of PKR<sup>−/−</sup> mice to endotoxemia produced significantly lower serum IL-1β and IL-18 levels, but quantitatively similar serum levels of TNF and IL-6 as compared to PKR<sup>+/+</sup> controls (Supplementary Fig. 20). Thus, PKR regulates inflammasome-dependent cytokine release in vivo.

To study the mechanisms, HEK293A cells, which do not normally express the NLRP3 components, were transfected with plasmids that co-express ASC, pro-caspase-1, and NLRP3. These modified cells were then co-transfected with plasmids that express PKR, or specific short hairpin RNA (shRNA) to suppress endogenous PKR. Overexpression of PKR significantly enhanced caspase-1 activation and IL-1β cleavage, and knockdown of endogenous PKR by shRNA abolished caspase-1 cleavage in the NLRP3 inflammasome-reconstituted cells (Fig. 2f, g). IL-1β cleavage was significantly abrogated by pharmacological inhibition of PKR (Supplementary Fig. 21). PKR overexpression failed to directly activate caspase-1 in the absence of NLRP3 (Supplementary Fig. 22), and did not enhance HMGB1 release in the absence of caspase-1 (Supplementary Fig. 23). Knock-down of endogenous eIF-2α, a PKR substrate, did not alter HMGB1 release and IL-1β cleavage in the NLRP3 inflammasome-reconstituted cells (Supplementary Fig. 24).

We therefore reasoned that PKR physically interacts with the NLRP3 inflammasome, and prepared mouse macrophage lysates for immunoprecipitation using anti-PKR antibodies. PKR pulled down NLRP3, and reciprocal immunoprecipitation of NLRP3 pulled down PKR (Supplementary Fig. 25). Similar observations were obtained in human THP-1 cells (Supplementary Fig. 26). PKR-NLRP3 complexes could not be detected in the PKR<sup>−/−</sup> macrophages (Supplementary Fig. 27). Co-expression of PKR and NLRP3 in HEK293A cells, followed by immunoprecipitation, confirmed the physical interaction between PKR and NLRP3. PKR failed to physically associate with the other cytosolic receptors and inflammasome family members NOD1, NLRP12, or NLRX1 (Supplementary Fig. 28). PKR co-immunoprecipitated with truncated forms of NLRP3 containing the PYD, NACHT, and LRR domains (Supplementary Fig. 29), and with the Walker A mutant form of NLRP3 (Supplementary Fig. 30), which can not bind ATP. Together with direct evidence that recombinant PKR forms a heteromeric protein complex with NLRP3 (Fig. 3a), these results indicate that PKR physically interacts with the inflammasome.

Exposure of PKR<sup>+/+</sup> macrophages to ATP significantly enhanced formation of NLRP3 and PKR complexes (Fig. 3b). Pharmacological inhibition of PKR phosphorylation by 2-AP and C<sub>13</sub>H<sub>8</sub>N<sub>4</sub>OS significantly suppressed the formation of NLRP3-PKR complexes (Fig. 3b). Addition of Poly I:C and ATP to NLRP3 and PKR in a cell-free system significantly induced PKR phosphorylation and increased the formation of NLRP3-PKR complexes (Fig. 3a).
Next, the NLRP3 inflammasome was reconstituted in a cell free system with recombinant NLRP3, ASC, pro-caspase-1 and PKR. Combining NLRP3 and ASC with Pro-caspase-1 failed to increase caspase-1 activity (Fig. 3c). Addition of PKR and Poly I:C/ATP significantly increased caspase-1 activity, which was inhibited by the addition of 2-AP (Fig. 3c). PKR activity is required in this cell free system, because poly I:C/ATP failed to increase NLRP3 inflammasome activity in the absence of PKR. Moreover, replacing PKR with a recombinant, mutant PKR (K296R) devoid of kinase activity, failed to activate the NLRP3 inflammasome (Fig. 3c). Although PKR is an autophosphorylating kinase, it was theoretically possible that PKR might phosphorylate inflammasome components directly. Phosphorylation of NLRP3, ASC, and Caspase-1 could not be detected, although Poly I:C/ATP significantly stimulated autophosphorylation of PKR (data not shown). To confirm that PKR autophosphorylation is involved in NLRP3 inflammasome activation, PKR K296R mutant and NLRP3 inflammasome components were co-expressed in HEK293A cells. PKR K296R mutant failed to bind NLRP3, whereas WT PKR did bind NLRP3 (Supplementary Fig. 31). Overexpression of PKR K296R mutant failed to activate the reconstituted NLRP3 inflammasome in HEK293A cells (Supplementary Fig. 31). Together, these data indicate that PKR physically interacts with NLRP3 and is critical for inflammasome activation.

Reasoning that PKR might associate with the inflammasome components during assembly, ATP stimulated macrophage lysates were subjected to gel filtration chromatography. We observed that PKR and NLRP3 eluted together with ASC and caspase-1 in the high molecular weight fraction of the ATP-stimulated macrophage extract (Fig. 3d, Supplementary Fig. 32). Inhibition of PKR activation by 2-AP reduced PKR in the high molecular weight inflammasome fraction (Fig. 3d, Supplementary Fig. 33). Expression of the PKR K296R mutant significantly reduced NLRP3 in the high-molecular weight inflammasome fraction, without significantly changing total NLRP3 expression (Supplementary Fig. 34). Rendering cells deficient in PKR also significantly impaired the formation of high-molecular weight protein NLRP3 inflammasome complexes, without altering total NLRP3 protein expression levels (Supplementary Fig. 35). Activation of macrophages by exposure to ATP, MSU, ALU, or *E. coli* significantly shifted caspase-1 from the low molecular weight, monomeric fraction, to the high-molecular weight protein complexes in PKR+/+ macrophages, but not in PKR−/− macrophages (Supplementary Fig. 35). Thus, activated PKR is an integral component of the assembled inflammasome.

Unexpectedly, PKR also physically interacted with NLRP1, AIM2, and NLRC4 when co-expressed in HEK293A cells (Fig. 4a). To address whether PKR might also regulate NLRP1, AIM2, and NLRC4 inflammasomes, macrophages were stimulated with anthrax lethal toxin (LT), Poly (dA:dT) transfection, or *S. Typhimurium* to activate NLRP1, AIM2, and NLRC4 inflammasome, respectively. This significantly enhanced PKR autophosphorylation (Supplementary Fig. 36). Inactivation of PKR by genetic deletion (Fig. 4b-d, Supplementary Fig. 37, 38) or pharmacological inhibition (Fig. 4e, Supplementary Fig. 39) significantly inhibited caspase-1 activation, IL-1β cleavage, and HMGB1 secretion. LDH release and IL-18 production were also significantly decreased in PKR−/− macrophages as compared with PKR+/+ macrophages, whereas TNF production was not suppressed in these conditions (Supplementary Fig. 40, 41). Overexpression of PKR significantly
enhanced NLRP1, AIM2, and NLRC4 inflammasome-induced caspase-1 activation and IL-1β cleavage in HEK293A cells (Fig. 4f, Supplementary Fig. 42). Thus, PKR regulates the activation of the NLRP3, NLRP1, AIM2, and NLRC4 inflammasomes, but PKR activity does not determine which inflammasome will be activated in response to a specific stimulus.

Previous observations suggested that macrophage death via pyroptosis might initiate deleterious inflammatory responses and compromise immunity during bacterial infection \(^5,15\), and that PKR can participate in bacteria-induced macrophage death \(^15\). To assess whether PKR deficiency impairs bacterial clearance, PKR\(^{+/+}\) and PKR\(^{-/-}\) mice were exposed to live \(E. coli\) (bearing a genetic marker) into the peritoneal cavity. Titers of the genetically labeled bacteria in the spleen and peritoneal cavity 24 hours later were significantly lower in PKR\(^{-/-}\) mice as compared to PKR\(^{+/+}\) controls (Supplementary Fig. 43), indicating that animals maintain the capacity to clear bacteria despite PKR deficiency.

This study establishes that PKR activity is integral to inflammasome assembly and activation. PKR physically interacts with inflammasome components, is important for caspase-1 activation, IL-1β cleavage, and HMGB1 release, and mediates inflammasome activity in a cell-free system. Although originally studied as an intracellular sensor of viral dsRNA, a broader role of PKR was recently suggested as a danger sensing molecule activated by cellular and metabolic stress \(^15-16,20\). Together with the established role of the inflammasome and HMGB1 in sterile and infection-associated inflammation \(^3,6,21-23\), the identification here of PKR as a critical regulator of inflammasome activity adds importantly to understanding mechanisms of innate immune responses to environmental, metabolic, and invasive signals.

Rapidly growing evidence links the inflammasome to the pathogenesis of obesity, type 2 diabetes, atherosclerosis, gout, sepsis, colitis, and other disease syndromes \(^4-5,10,18,24-25\). The development of therapeutics targeting the inflammasome requires knowledge of specific upstream signaling pathways that regulate inflammasome assembly and activation \(^25-26\). It should now be possible to design and develop therapeutics to inhibit inflammasome activity by specifically targeting PKR, without broadly impairing immunity, in the treatment of non-resolving inflammatory and metainflammatory syndromes.

**METHODS**

**Mice**

The PKR\(^{-/-}\) mice and their littermates wild-type controls originally are in the mixed 129Sv / BALB/C background as described previously \(^16\). In \(E. coli\) infection and endotoxemia experiments, we used the mice that had been bred into the C57Bl/6J genetic background. Genome-wide SNP analysis confirmed that about 98% of the genetic background of these mice is of C57Bl/6J. Animal care and experimental procedures were performed with approval from the Institutional Animal Care and Use Committees (IACUC) of The Feinstein Institute for Medical Research and Harvard University. PKR\(^{-/-}\) and PKR\(^{+/+}\) mice are genotyped with PCR primers (5’-GGAACTTTGGAGCAATGGA-3’; 5’-TGCCAATCACAAATCTAAAAC-3’; 5’-TGTTCTGTGGCTATCAGGG-3’ and 5’-)}
TGACGAGTT CTTCTGAGGG-3′ yielding a 240 bp wild-type DNA band and 460 bp mutant DNA band after electrophoresis in 2% agarose gel in TAE.

Reagents

Ultra-pure LPS and the NLRP3 inflammasome agonists ATP, monosodium urate crystal (MSU), and adjuvant aluminum (ALU) were obtained from Invivogen. The anti-NLRP3 antibodies (Cryo-2) were from Adipogen. The rabbit monoclonal anti-PKR (phospho T446) antibodies (E120) were from Abcam. Mouse HMGB1 mAb IgG2b 2G7 was described previously 7,10. eIF2α siRNA molecules and their negative controls were obtained from Life Technologies (Catalog: 4392420). Recombinant NLRP3 protein was obtained from Abnova. Recombinant Flag-tagged PKR protein was purified from PKR−/− mouse embryonic fibroblast cells stably expressing Flag-tagged PKR. Recombinant Flag-tagged ASC and Procaspase-1 protein were purified from HEK293A cells overexpressing Flag-tagged ASC and Procaspase-1 (Origene). Anti-human cleaved IL-1β (D116) was purchased from Cell Signaling. Anti-mouse IL-1β (sc-1251), anti-mouse caspase-1 (sc-514), and anti-human caspase-1 (sc-622) antibodies were from Santa Cruz.

Cell preparation and stimulation

Peritoneal macrophages were isolated and cultured as described previously 7. Primary bone marrow derived macrophages (BMDMs) and bone marrow derived dendritic cells (BMDCs) were cultured and differentiated in vitro as described previously 18. Human THP1 cells were differentiated for 3 h with 100 mM phorbol-12-myristate-13-acetate (PMA). 10⁶ peritoneal macrophages, BMDMs, BMDCs, or PMA-differentiated THP1 cells plated in 12-well plates were primed with ultra-pure LPS (500 ng/ml) for 4 h, and then stimulated with MSU (150 μg/mL), ALU (200 μg/mL) for 5 h, or live E. coli (MOI=20) for 6 h (stop the bacteria growth by adding antibiotics into culture medium 1 h after infection), or pulsed with ATP (5 mM) for 30 min or 1 hour as indicated. Ultra-pure LPS (1 ng/ml) primed mouse peritoneal macrophages were stimulated with Poly I:C (50 μg/ml) for 16 h. For salmonella infection, wild-type S. typhimurium was grown overnight in Luria-Bertani broth, then was reinoculated at a dilution of 1:100 and grown to mid-exponential phase (3 h) to induce expression of the salmonella pathogenicity island 1 type III secretion system. To minimize the involvement of NLRP3 inflammasome activation during salmonella infection, unprimed PKR+/+ and PKR−/− macrophages were infected with wild-type S. typhimurium (multiplicity of infection is from 5 to 100). The supernatant samples were collected 1 h after infection. To study AIM2 inflammasome activation, PKR+/+ and PKR−/− macrophages were transfected with Poly(dA:dT) using Lipofectamine 2000 at a concentration of (1 μg DNA plus 3.5 μl Lipofectamine 2000 per ml. The supernatant samples were collected 6 h after transfection. Caspase-1 activation, HMGB1 and LDH release were analyzed. To study the DNA-transfection-induced IL-1β cleavage, LPS-primed PKR+/+ and PKR−/− macrophages were transfected with Poly (dA:dT)/Lyovec (Invivogen) at a concentration of 5 μl/ml. There is minimum cell death with this approach. Cell lysates and precipitated supernatants were analysed by Western blot analysis.
Pharmacological inhibition of PKR

PKR inhibitor 2-Aminopurine (2-AP) was purchased from Sigma. 2-AP was dissolved in phosphate-buffered saline: glacial acetic acid (200:1) at 60°C for 60 min. PKR inhibitor C$_{13}$H$_8$N$_4$OS was purchased from Calbiochem. Ultra-pure LPS-primed peritoneal mouse macrophages, BMDMs, BMDCs, or PMA-differentiated THP1 cells were pre-treated with 2-Aminopurine (2-AP) (0.5 or 1.0 mM) or C$_{13}$H$_8$N$_4$OS (0.25 or 0.5 μM) for 1 to 4 h before stimulating with various inflammasome activators. Higher concentrations of above PKR inhibitors are not recommended due to off-target effects. Cell lysates and precipitated supernatants were analysed by Western blot.

ELISA

Cell culture supernatants and mouse serum samples were assayed for mouse IL-1β, IL-6, TNF, IL-18 (R&D Systems), and HMGB1 (IBL INTERNATIONAL) according to the manufacturer’s instructions.

Transfection

10$^6$ BMDCs from PKR$^{+/+}$ or PKR$^{-/-}$ mice were primed with ultra-pure LPS for 2 h, and then transfected with 5 μg of Poly I:C by lipofectamine 2000 for 6 h. In another set of experiment, ultra-pure LPS primed BMDCs (10$^6$ cells) from PKR$^{+/+}$ or PKR$^{-/-}$ mice were transfected with 5 μg of Poly I:C or E. coli RNA (Ambion) by electroporation using Nucleofector (Program V-01) and cell line Nucleofector Kit V (Amava AG). 3 h later, cell extracts and precipitated supernatants were obtained and analysed by Western blot analysis.

Reconstituted inflammasome in HEK293A cells

For the human NLRP3 inflammasome reconstitution assays, 0.2 × 10$^6$ HEK293A cells were seeded onto 24-well plates in cell culture media lacking antibiotics. 24 h later, cells were transfected with plasmids expressing pro-IL-1β and inflammasome components (Origene), such as ASC, pro-caspase-1, NLRP3, or NLRP1, using lipofectamine 2000. These modified cells were then co-transfected with plasmids that express PKR (Catalog: puno-hPKR, Invivogen), or specific shRNA (Catalog: ksina42-hpkr, Invivogen) to knockdown the endogenous PKR. The total amount of DNA was standardized to 600 ng per well using a control plasmid. 24 h later, cell lysates were harvested and analyzed for IL-1β maturation and Caspase-1 cleavage by Western blot analysis.

Immunoprecipitation

Antibodies against the PKR, NLRP3, Flag, or Myc were used to precipitate proteins from cell lysis in the presence of 20μl protein A/G beads (Santa Cruz) overnight at 4°C. Protein complexes were washed four times with lysis buffer, and then incubated at 95°C for 5 minutes and resolved by Western blot analysis.

Western-blot

Proteins from cell-free supernatants were extracted by methanol/chloroform precipitation as described previously 18. Cell extracts were prepared as described previously 7. Samples were separated by 4-20% SDS-PAGE or 4-20% native-PAGE and were transferred onto PVDF
membranes. The relative levels of HMGB1 in the culture medium were determined by Western blot analysis using recombinant HMGB1 protein to make a standard curve.

**PKR autophosphorylation assay**

PKR phosphorylation were assessed by PKR autophosphorylation assay as described previously\textsuperscript{15,16}. For mouse cells-derived samples, PKR autophosphorylation assay is recommended.

**Gel Filtration Chromatography**

As described early\textsuperscript{19}, fresh soluble lysates from mouse macrophages were prepared by hypotonic lysis and shearing through a 27-gauge needle. Soluble lysate (0.6 mg of total protein) was run on a Biosil 400 gel filtration column using a Bio-Rad Duoflow chromatography system in PBS with 2 mM DTT.

**Reconstituted inflammasome in a cell-free system**

Recombinant NLRP3, ASC and pro-caspase-1 were incubated with recombinant PKR and ATP (2.5mM) /Poly I:C (0.001 μg/mL) in the PKR reaction buffer (20 mM HEPES [pH7.4], 10 mM MgCl2, 40 mM KCl, 2 mM DTT) at 37 °C for 1 h. Caspase-1 activity was measured by hydrolysis of WEHD-pNA.

**E. coli-induced peritonitis and endotoxemia model**

PKR\textsuperscript{-/-} and PKR\textsuperscript{+/+} mice were injected i.p. with live \textit{E. coli} (2\times10^9 per mouse). 6 h later, blood was collected and serum levels of IL-1β, IL-18, HMGB1, and IL-6 were measured by ELISA. Meanwhile, peritoneal cavities were washed with 10 ml of PBS. The lavage fluids were analysed for neutrophil influx by Flow cytometry using the neutrophil marker GR-1. For bacterial titers experiments, PKR\textsuperscript{+/+} and PKR\textsuperscript{-/-} mice received live 2\times10^9 \textit{E.coli} into peritoneal cavity. And bacterial titers in both peritoneal cavity and spleen were measured 24 hour after \textit{E.coli} challenge. To prevent other bacterial contamination during sample collection process, the \textit{E.coli} had been transformed with an ampicillin-resistant gene. And bacterial titers were determined using ampicillin-containing LB agar plates. For endotoxemia experiments, PKR\textsuperscript{-/-} and PKR\textsuperscript{+/+} mice received 20mg/kg of LPS and blood was collected 2.5 hour later. Serum IL-1β, IL-18, TNF, and IL-6 levels were determined by ELISA.

**Analysis of HMGB1 by tandem mass spectrometry**

Detailed methods are available in Supplemetary Figures and Methods.

**Statistical analysis**

Student’s t-test and one-way ANOVA were used for comparison among all different groups. A p value < 0.05 was considered statistically significant.

**a-b.** LPS-primed PKR+/+ or PKR−/− macrophages were stimulated as indicated. **c.** PKR+/+ macrophages were stimulated or treated with 2-AP or C13H8N4OS (CNS) as indicated. **d-e.** PKR+/+ or PKR−/− mice (n=5) were injected with live *E. coli*. **f-g.** HEK293A cells were transfected as indicated. Caspase-1 activation and IL-1β cleavage were assessed by Western blot. Data are representative of at least three independent experiments. Levels of IL-1β, IL-18, HMGB1, and IL-6, in the supernatant (b) or serum (d) were determined by ELISA. Peritoneal lavage fluid was collected and neutrophil content measured by flow cytometry (e). Data shown are means ± SD. #, p<0.05 vs. wild-type infected groups.
Fig. 3. PKR physically interacts with NLRP3 and facilitates inflammasome activation.

a-b. Immunoprecipitation (IP) and Western-blot (WB) analysis of the physical interaction of PKR and NLRP3 in cell-free system using recombinant proteins (a) or LPS-primed macrophages stimulated with ATP or treated with of 2-AP or C13H8N4OS (CNS) as indicated (b). c. The NLRP3 inflammasome was reconstituted using recombinant proteins and ATP/Poly I:C as indicated. Caspase-1 activity was measured by hydrolysis of WEHD-pNA. d. PKR+/+ macrophages were stimulated or treated with 2-AP as indicated. Cell lysates were subjected to gel-filtration chromatograph and western-blot. Results are representative of three independent experiments.
Fig. 4. PKR regulates NLRP1, AIM2, NLRC4 inflammasome activation

a. HEK293A cells were transfected as indicated. The physical interaction of PKR and myc-tagged proteins was analyzed by Immunoprecipitation (IP) and Western-blot (WB) analysis.

b-d. LPS-primed (b) or unprimed (c, d) PKR+/+ or PKR−/− macrophages were stimulated with Anthrax lethal toxin (LT), or transfected with Poly (dA:dT), or infected with S. Typhimurium (S.T). MOI, multiplicity of infection. e. PKR+/+ macrophages were stimulated or treated with 2-AP as indicated. f. HEK293A cells were transfected as indicated. Caspase-1 activation, IL-1β cleavage, and HMGB1 secretion were assessed by Western-blot. Results are representative of at least three independent experiments.
