Cigarette smoke (CS) and nicotine delay neutrophil spontaneous death via suppressing production of diphosphoinositol pentakisphosphate

Yuanfu Xu, Hongmei Li, Besnik Bajrami, Hyunjee Kwak, Shannan Cao, Peng Liu, Jiaxi Zhou, Yuan Zhou, Haiyan Zhu, Keqiang Ye, and Hongbo R. Luo

Diphosphoinositol pentakisphosphate (InsP7), a higher inositol phosphate containing energetic pyrophosphate bonds, is beginning to emerge as a key cellular signaling molecule. However, the various physiological and pathological processes that involve InsP7 are not completely understood. Here we report that cigarette smoke (CS) extract and nicotine reduce InsP7 levels in aging neutrophils. This subsequently leads to suppression of Akt deactivation, a causal mediator of neutrophil spontaneous death, and delayed neutrophil death. The effect of CS extract and nicotine on neutrophil death can be suppressed by either directly inhibiting the PtdIns(3,4,5)P3/Akt pathway, or increasing InsP7 levels via overexpression of InsP6K1, an inositol hexakiphosphate (InsP6) kinase responsible for InsP7 production in neutrophils. Delayed neutrophil death contributes to the pathogenesis of CS-induced chronic obstructive pulmonary disease. Therefore, disruption of InsP6K1 augments CS-induced neutrophil accumulation and lung damage. Taken together, these results suggest that CS and nicotine delay neutrophil spontaneous death by suppressing InsP7 production and consequently blocking Akt deactivation in aging neutrophils. Modifying neutrophil death via this pathway provides a strategy and therapeutic target for the treatment of tobacco-induced chronic obstructive pulmonary disease.

In tobacco smoking-induced chronic obstructive pulmonary disease (COPD), chronic inflammation of the small airways and the lung parenchyma leads to fixed narrowing of small airways and alveolar wall destruction (emphysema) (1–4). The chronic inflammatory infiltrate is characterized by augmented numbers of alveolar leukocytes, including both B and T lymphocytes. However, the adaptive immune system may not be essential to the development of pulmonary emphysema in response to chronic tobacco exposure, because emphysema can still be induced in SCID mice, which lack functional lymphocytes (5). This finding indicates that innate inflammatory cells, such as neutrophils and macrophages, may play an essential role in the pathogenesis of COPD. Massive accumulations of neutrophils are frequently found in the bronchoalveolar lavage fluid (BALF) of patients with both stable and acute exacerbations of COPD (1–4). The enzymes and reactive oxygen species (ROSs) released by neutrophils can damage the surrounding tissues. Therefore, abnormal accumulation of neutrophils in the small airways and alveoli is likely to be a major contributor to the irreversible lung damage seen in tobacco-induced COPD (1–4).

The accumulation of neutrophils in the lungs can be due to increased neutrophil recruitment, or suppression of the clearance of apoptotic neutrophils by tissue macrophages (6, 7). In addition to these mechanisms, delayed spontaneous programmed cell death (apoptosis) of neutrophils can contribute to elevated numbers, contributing to unwanted and exaggerated inflammatory responses. Neutrophils are terminally differentiated cells, which normally have a very short lifespan (6–7 h in blood and 1–4 d in tissue), resulting in a rapid daily turnover (0.8–1.6 × 10⁹ cells per kg of body weight). They readily undergo apoptosis, and only apoptotic neutrophils can be recognized, engulfed, and cleared by macrophages. A reduction in neutrophil spontaneous death has been detected in tobacco-induced COPD patients (8). Some of the chemical constituents of cigarette smoke (CS), such as nicotine and acrolein, have been shown to directly delay neutrophil spontaneous death (9–11), providing a mechanism for the massive accumulation of neutrophils in the lungs of smoke-induced COPD patients. Here, we investigate the mechanism by which CS reduces neutrophil spontaneous death.

We previously established deactivation of the phosphatidylinositol 3,4,5 trisphosphate [PtdIns(3,4,5)P3]/Akt pathway as a causal mediator of neutrophil spontaneous death (12). Akt is a well-known cellular survival signal. Akt activity decreases dramatically during the course of neutrophil spontaneous death. In the current study, we demonstrate that both CS extract (CSE) and nicotine significantly suppress Akt deactivation in aging neutrophils, and thus delay neutrophil spontaneous death. Inhibition of PtdIns (3,4,5)P3/Akt signaling prevents CSE- and nicotine-induced delay of neutrophil spontaneous death. In addition, we demonstrate that the CSE- and nicotine-induced suppression of Akt deactivation is mediated by inhibition of diphosphoinositol pentakisphosphate (InsP7) production in aging neutrophils, establishing a mechanism by which CS regulates PtdIns(3,4,5)P3 signaling in neutrophils. Taken together, we conclude that CS- and nicotine-induced delay of neutrophil spontaneous death is a result of inhibition of InsP7 production, and the subsequent blockage of Akt deactivation, in aging neutrophils.

Results

CSE and Nicotine Block Akt Deactivation and Delay Neutrophil Spontaneous Death. We used an in vitro assay to assess the effect of CSE and nicotine on neutrophil spontaneous death. The number of neutrophils undergoing spontaneous death was quantified using FACS analysis. We used Annexin V, an anticoagulant protein with high affinity and selectivity for phosphatidylserine (PS), to detect PS exteriorization, and propidium iodide (PI), a membrane impermeable dye, to monitor cell membrane integrity. Consistent with previous reports (8–11), CSE and nicotine significantly reduced neutrophil spontaneous death. The most significant effects were observed at 36 h and 54 h (Fig. S1).

The authors declare no conflict of interest.

We recently established that deactivation of the PtdIns(3,4,5)P3/Akt pathway, a well known survival signal, is a causal mediator of neutrophil spontaneous death (12). Therefore, we examined whether CSE- and nicotine-induced reductions in neutrophil spontaneous death are a result of blockage of Akt deactivation. Akt is recruited to the plasma membrane through specific binding to PtdIns(3,4,5)P3. Only Akt molecules on the plasma membrane can be phosphorylated and activated by two phosphatidylinositol-dependent protein kinases (PDKs), thus Akt phosphorylation has been widely used as an indicator of Akt activation. During the course of neutrophil death, levels of phospho-Akt decreased significantly; whereas levels of total Akt remained unaltered. CSE and nicotine dramatically inhibited this neutrophil death-associated Akt dephosphorylation (Fig. 1A). We next examined cellular Akt activity by measuring glycogen synthase kinase-3β (GSK-3β), a substrate of Akt, as a downstream marker of functional Akt activation. Levels of phospho-GSK-3β declined during neutrophil death with a time course similar to the decline in levels of phospho-Akt. CSE and nicotine significantly suppressed this decline (Fig. 1B). Finally, we directly measured Akt protein kinase activity in neutrophil cell lysates using an in vitro assay, and observed that the kinase activity of Akt was significantly increased in neutrophils treated with CSE or nicotine (Fig. 1C). Taken together, our results demonstrate that CSE- and nicotine-induced inhibition of neutrophil spontaneous death is associated with up-regulation of PtdIns(3,4,5)P3/Akt signaling.

The cellular effect of nicotine is mediated by specific receptors. We next examined whether nicotinic acetylcholine receptors (nAChRs) are involved in nicotine-induced delay of neutrophil death. nAChRs are primarily known for their action as ligand-gated ion channels that transduce action potentials across neuronal synapses. However, various nAChRs have also been detected on hematopoietic cells, including neutrophils (13, 14). Nicotinic acetylcholine receptors consist of five molecular subunits (α1–10, β1–4, δ, ε, and γ) that surround a central pore through which ions pass. To date, 17 nAChR subunits have been identified, which are divided into three functional classes: muscle subunits (α1, β1, δ, ε, and γ), neuronal subunits (α1–6 and β2–4) that form in pairwise αβ combinations, and subunits α7–9 that can form homomeric nAChRs. We used specific nAChR inhibitors to reveal which subunits are involved in nicotine-induced up-regulation of Akt phosphorylation during neutrophil death. Benzoquinonium dibromide (nonselective), MG 624 (α7 specific), and methyllycaconitine (α7 specific) inhibited nicotine-induced up-regulation of Akt phosphorylation. Dihydro-β-erythroidine hydrobromide (α4 specific), ACV 1 (α9x10 specific), α-Conotoxin PIA (α6 specific), α-Conotoxin AuIB (α3δ specific), dihydro-β-erythroidine hydrobromide (α4 specific), and α-Conotoxin EI (α1β1γ6 specific) were essentially ineffective inhibitors of nicotine-induced up-regulation of Akt phosphorylation (Fig. 1D). These results suggest that nicotine-induced delay of neutrophil death is indeed mediated by nAChRs, in particular those composed of α7 subunits.

CSE contains over 4,000 chemicals. Surprisingly, CSE-induced up-regulation of Akt phosphorylation in aging neutrophils could be partially suppressed by the AChR antagonists benzoquinonium dibromide, MG 624, or methyllycaconitine, suggesting that CSE-induced delay of neutrophil death is at least partially mediated by the nicotine in CS (Fig. 1 E and F).

**Effects of CSE and Nicotine on Neutrophil Spontaneous Death Can Be Suppressed by Inhibitors of the PtdIns(3,4,5)P3/Akt Pathway.** We next suppressed PtdIns(3,4,5)P3/Akt signaling using pharmacological inhibitors. First, we used two newly developed Akt inhibitors, SH5 and SH6, to suppress Akt signaling in neutrophils. Because PI3-kinase is upstream of Akt, and inhibition of PI3-kinase is associated with deactivation of Akt, we also treated neutrophil cultures with two PI3-kinase inhibitors, LY294002 and wortmannin. Treatment with all of these drugs markedly reduced Akt phosphorylation without altering total Akt levels (Fig. 2A) and promoted the death of CSE-treated neutrophils measured by FACS analysis (Fig. 2B). Because the inositol phosphates InsP7
and Ins(1,3,4,5)P4 compete with PtdIns(3,4,5)P3 for binding to the pleckstrin homolog (PH) domain, and thereby attenuate the membrane translocation of PH-domain-containing proteins (15–17), we also tried to suppress PtdIns(3,4,5)P3/Akt signaling using inositol phosphates. However, inositol phosphates, such as Ins(1,3,4,5)P4 and InsP7, are highly hydrophilic molecules and cannot passively cross the plasma membrane. Intracellular levels of Ins(1,3,4,5)P4 or InsP7 can therefore not be raised by simply adding the compounds to the culture medium. To circumvent this problem, we used a membrane-permeable derivative of Ins(1,3,4,5)P4, 2,6-di-O-butyryl-myo-inositol 1,3,4,5-tetakis-phosphate octakis\[-\]

**Fig. 2.** Inhibiting Akt activity reverses CSE- and nicotine-induced delay of neutrophil spontaneous death. (A) Deactivation of Akt by PI3-kinase or Akt inhibitors. Freshly prepared human neutrophils were treated with 20 μM LY294002, 50 nM wortmannin, 10 μM SH5, or 10 μM SH6 in the presence or absence of 2% CSE for 15 h. Akt activity (phosphorylation) was assessed by Western blotting analysis as described above. (B) Cell viability was assessed by FACS analysis 34 h after blood was drawn from the donors. The results are the means of three independent experiments. Bars indicate mean ± SD. *P < 0.001 versus cells treated with CSE alone by Student t test. (C and D) Deactivation of Akt was achieved by treatment with Bt2Ins(1,3,4,5)P4/AM. Neutrophils were cultured in 50 μM Bt2Ins(1,3,4,5)P4/AM or Bt2Ins(1,3,4,6)P4/AM (as a control), and Akt phosphorylation and cell viability were assessed as described above. (E–H) Human neutrophils were cultured in 1 μM nicotine. All experiments were conducted as described in A–D.
exclusively nuclear (20). In a recent study, we reported that PtdIns(3,4,5)P3/Akt signaling in neutrophils is mainly regulated by InsP6K1 (16). To further investigate the role of InsP7 in regulating PtdIns(3,4,5)P3 signaling in neutrophil spontaneous death, we elevated the intracellular level of InsP7 by overexpressing InsP6K1 in HL60 cells, in which specific genes can be easily overexpressed (Fig. 4A). Consistent with our previous results (16), we detected significantly more InsP7 in HL60 cells overexpressing InsP6K1, whereas a control construct or a “kinase-dead” mutant of InsP6K1 had no effect. The augmented InsP7 production was also detected in InsP6K1-overexpressing cells treated with CSE or nicotine, and this up-regulation remained during spontaneous death (Fig. 4B). Consequently, Akt phosphorylation (Fig. 4C) and activation (Fig. 4D) was significantly suppressed in dHL60 cells overexpressing InsP6K1, but not in those overexpressing the kinase-dead InsP6K1 mutant, indicating that InsP6K1-mediated conversion of InsP6 to InsP7 is essential for the suppression of PtdIns(3,4,5)P3 signaling. We next examined the effect of InsP6K1 overexpression on the spontaneous death of CSE- or nicotine-treated neutrophils. Consistent with the reduction in Akt activation, the CSE- and nicotine-induced delay of neutrophil death was abolished in cells overexpressing InsP6K1. More than 65% of neutrophils overexpressing the control construct or the kinase-dead mutant of InsP6K1 survived after 36 h in cultures containing CSE or nicotine, whereas less than 35% neutrophils overexpressing the active InsP6K1 survived under the same conditions (Fig. 4E). Finally, the effect elicited by InsP6K1 overexpression could be completely reversed by treating cells with TNP [N(2)-(m-trifluoromethyl)benzyl]N(6)-(p-nitrobenzyl)purine, a selective inhibitor of InsP6K (Fig. 4F and G). Taken together, these results further confirm that reduced InsP7 production is responsible for CSE- and nicotine-induced delay of neutrophil death.

**Disruption of InsP6K1 Augments CS-Induced Neutrophil Accumulation and Lung Damage.** Alterations in neutrophil death will lead to changes in neutrophil accumulation at sites of inflammation. It has been well documented that CS-induced delay of neutrophil spontaneous death plays a critical role in neutrophil accumulation and lung damage in smoke-induced COPD patients (9–11). We explored the role of InsP6K1 in regulating neutrophil accumulation and lung damage using a CS-induced COPD animal model (Fig. 4 H–J). Neutrophil accumulation in inflamed lungs was assessed by measuring neutrophil numbers in BAL fluid (Fig. 4H). Very few neutrophils were detected in the lungs of unchallenged mice. The number of neutrophils in BALF increased dramatically in response to CS, reaching 2 × 10^7 after 6 h of exposure. InsP6K1 KO mice showed a dramatic increase in CS-induced neutrophil recruitment, with nearly 3.8 × 10^7 neutrophils present in BALF after 6 wk (Fig. 4H). Lung inflammation is always associated with significant cytokine and chemokine release. Accordingly, we measured the level of several cytokines/chemokines, including TNF-α, IL-1β, IL-6, Macrophage inflammatory protein 2 (MIP-2), and Keratinocyte Chemotactant (KC) in the inflamed lungs of both WT and InsP6K1 KO mice. In BALF collected at 6 wk, the concentrations of all five cytokines/chemokines were significantly increased in the InsP6K1 KO mice (Fig. 4I). Dramatic increases in lung neutrophils and hyperinflammation leads to aggravated lung damage, which is usually accompanied by vascular leakage. We consistently detected augmented pulmonary edema formation, measured as total BALF protein level, in the lungs of InsP6K1 KO mice (Fig. 4J). Taken together, these results confirmed that disruption of InsP6K1 can augment CS-induced neutrophil accumulation and lung damage.

**Discussion**

InsP7, a higher inositol phosphate containing energetic pyrophosphate bonds (18, 21), has recently been established as a key signaling molecule in eukaryotic cells (22–25). In mammalian cells, InsP7 has been implicated in several cellular functions, including vesicular trafficking and exocytosis (26, 27), apoptosis (28–31), insulin disposition (32), insulin sensitivity, and weight gain (33). We recently showed that InsP7 also represents a
mechanism for controlling optimal PtdIns(3,4,5)P3/Akt pathway activation in neutrophils. As a key signaling molecule, PtdIns(3,4,5)P3 exerts its function by mediating protein translocation via binding to their PH domains. Akt contains a PH domain that specifically binds PtdIns(3,4,5)P3. The PtdIns(3,4,5)P3-mediated membrane translocation of Akt is essential for its phosphorylation and activation, and was previously thought to be dependent solely upon the concentration of PtdIns(3,4,5)P3 in the membrane. We demonstrated that two inositol phosphates, InsP7 and Ins(1,3,4,5)P4, compete for Akt–PH domain binding with PtdIns(3,4,5)P3 both in vitro and in vivo, providing another level of regulation for Akt membrane translocation and activation (15). The amount of InsP7 in neutrophils is tightly regulated. There is substantial InsP7 in unstimulated cells, which prevents neutrophil hyperactivation and ensures an optimal cellular inflammatory response. The cellular concentration of InsP7 rapidly decreases after stimulation with chemoattractants, which allows the induction of sustained PtdIns(3,4,5)P3 signal in responding neutrophils (16). Reducing InsP7 production via InsP6K1 disruption augments chemoattractant-elicted PtdIns(3,4,5)P3 signaling in neutrophils. Consequently, these neutrophils have greater phagocytic and bactericidal ability, and amplified NADPH oxidase-mediated production of ROSs. In the current study, we show that CSE and nicotine can also reduce InsP7 production and augment Akt signaling in aging neutrophils (Fig. S3). The mechanism by which InsP7 level is down-regulated in nicotine-treated neutrophils is largely unknown. It likely involves activation of inositol pyrophosphate phosphatase and/or deactivation of InsP6 kinase. Our results indicate that the nicotine-elicited effect is mediated by α7-containing nAChRs. Interestingly, it has been reported that nicotine-induced activation of nAChR can elicit Akt hyperactivation in many other cell types, including airway epithelial cells, adrenal chromaffin cells, bone-marrow-derived dendritic cells, neurons, and certain cancer cells (34, 35). It is possible that some of these effects may also be due to nicotine-induced reduction of InsP7 production.

CSE- and nicotine-induced reduction of InsP7 production leads to augmented Akt signaling and delayed neutrophil spontaneous death. Intriguingly, our previous study revealed that disruption of InsP6K1 abolishes chemoattractant-elicited InsP7 production, but does not alter the rate of neutrophil spontaneous death.
death (16). It appears that disruption of InsP6K1 does not affect Akt activation in aging neutrophils (Fig. S4). One explanation could be elevated ROS production in InsP6K1-deficient neutrophils. We recently identified ROS as negative regulators of PtdIns(3,4,5)P3/Akt signaling (36). Thus, disruption of InsP6K1 not only reduces InsP7 level, but also elevates ROS levels, resulting in unaltered Akt activation. Nicotine stimulation reduces InsP7 levels in aging neutrophils, with no effect on ROS production; in fact, a previous study has suggested that nicotine may even inhibit ROS production in neutrophils (37). As a result, treatment with nicotine significantly enhances Akt activity during neutrophil spontaneous death.

Materials and Methods

Animal Care. Mice aged 8–14 wk were used in this study. All procedures involving mice were approved and monitored by the Children’s Hospital Boston Institutional Animal Care and Use Committee. InsP6K1−/− mice were generated as described (16). The corresponding WT littermates were used as paired controls for InsP6K1+/− mice.

Neutrophil Spontaneous Death. Neutrophils were cultured for indicated times and stained using an Annexin V Detection kit (Caltag Laboratories) (12). FACS was performed using a FACSCanto II flow cytometer (Becton Dickinson). The annexin V and propidium iodide (PI) double negative cells were defined as live cells. The related methods, such as isolation of neutrophils, FACS analysis, Western blotting, Akt kinase assay, preparation of CSE, measurement of PtdIns(3,4,5)P3 levels, nucleofection, PH domain membrane translocation, and measurement of inositol phosphates, are described in detail in SI Materials and Methods.

CS-Induced COPD. WT or InsP6K1 KO mice were placed in an 18-L chamber and exposed to CS generated from 3R4F research cigarette (University of Kentucky, Lexington). They were exposed to five cigarettes (about 2 h) per day, 5 d per week for a total of 6 wk. Mice were euthanized 1 h after the last exposure to CS. Preparation of BALF, differential cell counting, and measurement of cytokine and total protein levels in BALF are described in detail in SI Materials and Methods.

Statistical Analysis. Values shown in each figure represent mean ± SD. Statistical significance was calculated with the Student t test. Differences were considered significant for P values less than 0.005.

SI Materials and Methods

Mice Neutrophils. Mice aged 8–14 wk were used in this study. All procedures involving mice were approved and monitored by the Children's Hospital Boston Institutional Animal Care and Use Committee. Mouse bone marrow neutrophils were isolated from the femur and tibia of 10-wk-old mice (1). Isolated neutrophils were cultured in RPMI medium 1640 containing 10% heat-inactivated FBS at a density of 2 × 10^6 cells per mL. Inositol hexakisphosphate kinase 1 double mutant (InsP6K1−/−) mice were generated as described (1). The corresponding WT littermates were used as paired controls for InsP6K1−/− mice.

Human Primary Neutrophils. We isolated human primary neutrophils from discarded white blood cell filters (WBF2 filter, Pall Corporation), which were provided by the Blood Bank Lab at the Children's Hospital Boston. Neutrophils were purified using a standard protocol (2). Briefly, erythrocytes were sedimented by adding an equal volume of dextran/saline solution (5% dextran T-500 in 0.9% NaCl) at room temperature for 25 min. The erythrocyte-depleted supernatants were then layered on Lymphocyte Separation Medium (1.077 g/mL Ficoll–Hypaque solution, Voigt Global Distribution) and centrifuged at 400 × g at room temperature for 20 min. Contaminated erythrocytes in the neutrophil pellets were lysed after a brief (<30 s) treatment with 0.2% NaCl. Neutrophils were then resuspended in RPMI medium 1640 containing 10% heat-inactivated FBS as a density of 4 × 10^6 cells per mL and maintained at 37 °C. The purity of neutrophils was >97% as determined by both Wright–Giemsa staining and FACS analysis with CD15 antibody. We routinely obtain about 1–3 × 10^7 neutrophils from one filter (450 mL of blood from a healthy donor). We have compared the neutrophils that we collected through filter with those obtained by vein puncture and stored in anticoagulant testing tubes, and found that the filtration method does not impair neutrophil function (e.g., chemotaxis and the time course of cell death). All blood is drawn from healthy blood donors. All protocols have been approved by the Children’s Hospital Boston Institutional Review Board.

Preparation of Cigarette Smoke Extract. Aqueous cigarette smoke (CS) extract (CSE) was prepared by a widely used method. The smoking apparatus consisted of a 50-mL plastic syringe with a three-way stopcock, and one end was immersed in a 50-mL water bath (CS) extract (CSE) was prepared by a widely used method. The smoking apparatus consisted of a 50-mL plastic syringe with a three-way stopcock, and one end was immersed in a 50-mL water bath. Cigarette smoke was collected through a syringe and then slowly bubbling the smoke into the syringe and then slowly bubbling the smoke into the syringe. One cigarette was smoked per 10 mL of medium. CSE was prepared using Kentucky research cigarettes 3R4F (University of Kentucky, Lexington).

FACS Analysis of Neutrophil Spontaneous Death. Neutrophils were cultured for indicated time and stained using an Annexin V Detection kit (CalTag Laboratories) following a protocol provided by the manufacturer as described (2). FACS was performed using a FACSCanto II flow cytometer (Becton Dickinson) equipped with a 488 nm argon laser. Ten thousand cells were collected and analyzed using the BD FACSDiva software (Becton Dickinson). The annexin V and propidium iodide (PI) double negative cells were defined as live cells. The percentage of dead cells was calculated as 100 minus the percentage of live cells. The results are the means (±SD) of three independent experiments. To assess the effect of nicotine on neutrophil death, the cells were cultured in the presence of 1 μM nicotine (Sigma-Aldrich). Acetylcholine receptor (AChR) antagonists benzoquinonium dibromide, MG 624, methyllycaconitine, dihydro-β-erythroidine hydrobromide, ACV 1, α-Conotoxin PI A, α-Conotoxin Ax IB, dihydro-β-erythroidine hydrobromide, and α-Conotoxin E1 were purchased from Tocris Bioscience.

Western Blot Analysis. Neutrophils were kept at 4 × 10^6 cells per mL in the spontaneous death assay. At each indicated time point, neutrophils (4 million cells per data point) were spun down and lysed immediately with 100 μL of boiling protein loading buffer (Invitrogen). Samples were incubated at 100 °C for 5 min and transferred on ice. After a brief sonication (5–10 s), 25 μL of lysis was used for Western blot analysis. For Western blotting, a 4–20% SDS/PAGE System (Invitrogen) was used for protein separation and an ECL Western Blotting kit (Amersham) was used for protein detection.

In Vitro Akt Protein Kinase Activity Assay. Akt kinase activity was measured using a KinaseSTARTM Akt Activity Assay kit (BioVision) following a protocol provided by the manufacturer. Briefly, neutrophils were collected and a 30-μL neutrophil pellet was resuspended in 200 μL of PBS and filter-lysed through two layers of 5-μm filter membrane (3). Akt molecules were then immunoprecipitated with an Akt specific antibody included in the Akt Activity Assay kit. Activity of Akt was determined in a kinase reaction using recombinant GSK-3β as substrate. Phosphorylation of the GSK-3β was analyzed by Western blot analysis using a phospho-GSK-3β-specific antibody included in the kit.

Measurement of PtdIns(3,4,5)P3 Levels in Neutrophils. Human neutrophils were cultured in RPMI medium 1640 containing 10% heat-inactivated FBS as a density of 4 × 10^6 cells per mL at 37 °C for indicated time and cellular phosphatidylinositol 3,4,5 triphosphate [PtdIns(3,4,5)P3] levels were measured using a Echelon Mass ELISA kit (Echelon Biosciences). Briefly, PtdIns (3,4,5)P3 was extracted from 50 million purified neutrophils following the manufacturer’s lipid-extraction protocol. The samples were incubated with a PtdIns(3,4,5)P3 detector protein and then added to a PtdIns(3,4,5)P3-coated microplate for competitive binding. A peroxidase-linked secondary detector and colorimetric detection were used to quantify the PtdIns(3,4,5)P3 detector protein bound to the plate. The colorimetric signal is inversely proportional to the amount of PtdIns(3,4,5)P3 in the sample.

Gene Transfer (Nucleofection) and Pleckstrin Homolog Domain Membrane Translocation Assay. To overexpress Pleckstrin homolog domain (PH)Akt−GFP in neutrophils, 3 × 10^6 mouse neutrophils were transfected with 2.0 μg of PHAkt−GFP DNA using an Amaxa nucleofector device in accordance with the manufacturer’s protocol (1, 4). Mouse neutrophils were incubated in RPMI medium 1640 containing 10% heat-inactivated FBS at a density of 2 × 10^6 cells per mL for indicated times and then transferred onto a LabTek chambered cover glass. Membrane translocation of PHAkt−GFP was visualized using an Olympus IX-71 microscope with a 40x oil immersion objective. The average membrane fluorescence intensities were measured with ImageJ software as described (1, 4, 5). To measure inositol phosphate levels and Akt activation following InsP6K1 overexpression, 6-d differentiated HL60 cells were transfected with a mixture of Myc-InsP6K1 plasmid (or Myc vector alone as control) (4 μg) and pEGFP
A transfection efficiency of >80% and a cytotoxicity of <5% were routinely achieved.

**Analysis of Inositol Phosphates in HL60 Cells.** Inositol Phosphates in neutrophil like differentiated HL60 Cells was analyzed as previously described. Briefly, HL60 cells were cultured in RPMI medium 1640 supplemented with 10% (vol/vol) FBS and 4 mM glutamine in the presence of [3H]inositol (20 μCi/mL) (PerkinElmer). Cells were plated at a density of 1 × 10⁶ cells per ml in 4 mL of medium, with 1 volume of fresh medium containing [3H]inositol added every 2 d, followed by culture for another 6 d in the presence of DMSO (1.3%, vol/vol). The neutrophil like differentiated HL60 cells were then cultured in the absence or presence of CSE (2%) or nicotine (1 μM) for indicated time, and the inositol phosphates were extracted and analyzed by HPLC as described (6). To inhibit InsP6K activity, the cells were treated with 10 μM N(2)-(m-(trifluoromethy) benzyl) N(6)-(p-nitrobenzyl)purine (TNP) (Sigma-Aldrich) for 2 h.

**CS-Induced Chronic Obstructive Pulmonary Disease.** WT or InsP6K1 KO mice were placed in an 18-L chamber and exposed to CS generated from 3R4F research cigarette (University of Kentucky, Lexington). They were exposed for five cigarette (about 2 h) per day and 5 d per week for a total of 6 wk. One hour after the last exposure to CS, mice were euthanized with an overdose of sodium pentobarbital. The lung was lavaged with 3 × 0.7 mL of 10 U/mL ice-cold heparinized saline. The total amount of cells in the lungs was counted by hemocytometer. Differential cell counts were conducted on cytospin preparations stained with a modified Wright–Giemsa stain (Volu-Sol) (7).

**Bronchoalveolar Lavage Fluid Cytokine and Chemokine Levels and Total Protein Levels.** BAL was done with 1 mL of cold PBS/15 mM EDTA flushed back and forth three times. The levels of TNF-α, IL-1β, IL-6, Macrophage inflammatory protein 2 (MIP-2), and Keratinocyte Chemotactrant (KC) in the bronchoalveolar lavage fluid (BALF) were measured with ELISA kits following a protocol provided by the manufacturer (R&D Systems). Protein concentration was measured in the BALF using the Bio-Rad protein assay reagent. The standard curve was constructed using BSA (7).

**Statistical Analysis.** Values shown in each figure represent mean ± SD. Statistical significances were calculated with the Student t test. Differences were considered significant for P values less than 0.005.

---

**Fig. S1.** CS and nicotine delay neutrophil spontaneous death. (A) Time course of neutrophil spontaneous death. All values represent mean ± SD of three separate experiments. (B) Human primary neutrophils were cultured in the presence of 2% CSE or 1 μM nicotine. Cell death was analyzed as described in Fig. 2. *P < 0.001 versus untreated cells by ANOVA test.
Fig. S2. Treatment with CSE or nicotine does not alter Ins(1,3,4,5)P4 level in aging neutrophils. HL60 cells were differentiated and labeled with [3H]inositol. The neutrophil like differentiated cells were incubated in the absence or presence of CSE (2%) or nicotine (1 mm) for indicated time. Inositol phosphates were extracted and analyzed by HPLC. All of the data were normalized to the total amount of protein extracted from each sample. Data are presented as mean values from three independent experiments whose results varied less than 5%. As reported (6), Ins(1,3,4,5)P4 production could be induced by fMLP stimulation (100 nM for 30 s).

Fig. S3. CS-induced blockage of Akt deactivation leads to delayed neutrophil spontaneous death, contributing to the pathogenesis of CS-induced chronic obstructive pulmonary disease. Activation of Akt is essential for cell survival. We recently reported that Akt deactivation is a causal mediator of neutrophil spontaneous death (2). In healthy cells, activation of Akt is maintained by extracellular ligands such as growth factors and chemokines. Akt is translocated onto the plasma membrane through its specific binding with PtdIns(3,4,5)P3. Only the Akt molecules on the plasma membrane can be phosphorylated and activated. InsP7 competes for Akt-PH domain binding with PtdIns(3,4,5)P3, and thus negatively regulates Akt membrane translocation and activation. PtdIns(3,4,5)P3/Akt signaling is diminished during neutrophil spontaneous death; and this PtdIns(3,4,5)P3/Akt deactivation plays and essential role in neutrophil death. CS suppresses Akt deactivation and thus reduces neutrophil spontaneous death. The effect of CS is mediated by nicotine-induced down-regulation of InsP7, a negative regulator of PtdIns(3,4,5)P3/Akt signaling.
**Fig. S4.** Disruption or inhibition of InsP6K1 does not inhibit Akt deactivation during neutrophil spontaneous death. (A) WT and InsP6K1 KO mouse neutrophils were cultured for indicated time period. Total and phosphorylated Akt were detected by Western blot using anti-Akt and anti-Phospho-Akt (Ser473) antibodies, respectively. Relative amounts of phosphorylated Akt were quantified using NIH Image software as described in Fig. 1. Data presented are the means (±SD) of three independent experiments. (B) Human primary neutrophils were cultured in the absence or presence of InsP6K inhibitor TNP (10 μM) for indicated time period. Relative amounts of phosphorylated Akt were quantified using NIH Image software as described above. All values represent mean ± SD of three separate experiments.
