PERSPECTIVE

Using Drugs to Discriminate — Adverse Selection in the Insurance Marketplace

Douglas B. Jacobs, Sc.B., and Benjamin D. Sommers, M.D., Ph.D.

The standard argument for regulating risk classification is that it’s unfair for employers to discriminate or insurers to charge different rates because of immutable risks. GINA’s exceptionalism may, in part, reflect a genetic determinism and therapeutic nihilism that were prevalent in 1995, when Congress first considered this issue, but that will be far less salient in the future. Although genetic determinism with regard to highly penetrant mendelian conditions may persist, it’s now clear that everyone carries genetic variants that will influence, but in most cases not exclusively determine, one’s health status. The science of genomic medicine is moving rapidly toward multiscale network and systems biology by elucidating the complex interactions of genomics, physiology, and environmental influences. In a future informed by this science, we may be able to personalize risk stratification and then tailor diet, exercise, and pharmaceuticals and even edit genes to promote wellness by preventing and minimizing illness. Eventually, the notion of immutable genetic risks may become obsolete, and it may be less important to grant genetic information special protection than to protect everyone from all forms of medical discrimination. As all medicine in a sense becomes genomic medicine, perhaps the genetic nondiscrimination secured by GINA will translate into nondiscrimination in all of medicine.

premiums and mandated that plans insure all comers. In combination with premium subsidies and the Medicaid expansion, these policies have resulted in insurance coverage for an estimated 10 million previously uninsured people in 2014.¹

There is evidence, however, that insurers are resorting to other tactics to dissuade high-cost patients from enrolling. A formal complaint submitted to the Department of Health and Human Services (HHS) in May 2014 contended that Florida insurers offering plans through the new federal marketplace (exchange) had structured their drug formularies to discourage people with human immunodeficiency virus (HIV) infection from selecting their plans. These insurers categorized all HIV drugs, including generics, in the tier with the highest cost sharing.²

Insurers have historically used tiered formularies to encourage enrollees to select generic or preferred brand-name drugs instead of higher-cost alternatives. But if plans place all HIV drugs in the highest cost-sharing tier, enrollees with HIV will incur high costs regardless of which drugs they take. This effect suggests that the goal of this approach — which we call “adverse tiering” — is not to influence enrollees’ drug utilization but rather to deter certain people from enrolling in the first place.

To explore the implications of this practice, we analyzed adverse tiering in 12 states using the federal marketplace: 6 states with insurers mentioned in the HHS complaint (Delaware, Florida, Louisiana, Michigan, South Carolina, and Utah) and the 6 most populous states without any of those insurers (Illinois, New Jersey, Ohio, Pennsylvania, Texas, and Virginia; for details, see the Supplementary Appendix, available with the full text of this article at NEJM.org). We examined the plans with the lowest, second-lowest, median, and highest premiums on the “silver” level in each state, analyzing formularies and benefit summaries to assess cost sharing for nucleoside reverse-transcriptase inhibitors (NRTIs), one of the most commonly prescribed classes of

**Average HIV-Related Costs for Adverse-Tiering Plans (ATPs) versus Other Plans.**

I bars represent 95% confidence intervals, and P values represent results of t-tests for significant differences between ATPs and other plans for each outcome. The “total annual average cost of HIV regimen” is the sum of the annual premium and the average annual out-of-pocket cost of HIV regimens. The HIV treatment regimen that was used for this calculation was emtricitabine, tenofovir, and efavirenz, a commonly prescribed single-pill regimen. Out-of-pocket spending was capped at each plan’s out-of-pocket maximum under the Affordable Care Act, typically $6,350.

rheumatoid arthritis showed sim-
ilar evidence of adverse tiering, with 52% of marketplace plans requiring at least 30% coinsur-
ance for all covered drugs in at least one class. Thus, this phe-
nomenon is apparently not limited to just a few plans or conditions.

Adverse tiering is problematic for two reasons. First, it puts sub-
stantial and potentially unexpect-
ed financial strain on people with chronic conditions. These enroll-
ees may select an ATP for its lower premium, only to end up paying extremely high out-of-
pocket drug costs. These costs may be difficult to anticipate, since calculating them would re-
quire knowing an insurer’s negoti-
tiated drug prices — information that is not publicly available for most plans.

Second, these tiering practices will most likely lead to adverse selection over time, with sicker people clustering in plans that don’t use adverse tiering for their medical conditions. After enroll-
ees with chronic conditions real-
ize they’re incurring higher-than-
expected costs in an ATP, some will switch to different plans dur-
ing the next enrollment period. Over time, thanks to word-of-
mouth or clinicians’ advice, plans offering generous prescription-
drug benefits may see a large influx of sick enrollees, which would reduce their profits and could lead to a race to the bottom

Adverse tiering will most likely lead to adverse selection over time, with sicker people clustering in plans that don’t use adverse tiering for their medical conditions.

in drug-plan design. Although the ACA’s risk-adjustment, reinsur-
ance, and risk-corridor programs provide some financial protec-
tion to insurers whose enrollees are sicker than average, the exist-
ence of adverse tiering in 2014 suggests that selection opportu-
nities remain. Furthermore, the reinsurance and risk-corridor pro-
grams will be phased out after 2016, which will only increase insurers’ incentives to avoid sick enrollees.

Several policies could reduce the harms associated with adverse tiering. One approach to address-
ing unexpectedly high out-of-
pocket costs for people with chronic conditions is price trans-
parency. Insurers could be re-
quired to list on their formulary each drug’s “estimated price to enrollee,” based on the negotiat-
ed price and the copayment or coinsurance. However, if adopted in isolation, price transparency would probably accelerate the adverse-selection process.

Additional policies are needed to combat selection and end ad-
verse tiering altogether. One po-
tential approach with a policy precedent would be establishing protected conditions in drug for-
mularies. Medicare Part D has designated several “protected classes” of drugs, including those used for HIV, seizures, and can-
cer, in order to maintain patients’
access to them. A similar approach in the marketplaces could set an upper limit on cost sharing for medications for protected conditions. Such a policy would reduce financial exposure for people with these conditions, even if they chose suboptimal plans — which, to judge from studies of consumers’ plan selection, is likely to remain a common occurrence. Other safeguards for protected conditions, such as limits on prior-authorization requirements, could also be implemented.

An important additional step would be to require marketplace plans to offer drug benefits that meet a given actuarial value — meaning that the percentage of drug costs paid by the plan (rather than the consumer) would have to exceed a particular threshold. This level could be set at the overall actuarial value for a given plan (i.e., 70% for silver plans) or above it. Under this approach, in order to significantly increase cost sharing for one drug, an insurer would have to reduce cost sharing for another drug. This step is crucial because it encompasses treatment of all health conditions — not just protected conditions — and addresses non-formulary-based methods of passing costs on to consumers (e.g., drug-specific deductibles) that may induce adverse selection.

Stopping adverse drug tiering will not completely eliminate discrimination in the insurance marketplace. Some insurers will invariably think of new ways to dissuade sick enrollees from joining their plans. Eliminating premium discrimination on the basis of health status was one of the ACA’s chief accomplishments in the nongroup insurance market and one of the law’s most popular features. Preventing other forms of financial discrimination on the basis of health status — with the attendant risks of adverse selection in the marketplace — will require ongoing oversight. The ACA has already made major inroads in designing a more equitable health care system for people with chronic conditions, but the struggle is far from over.

Death Takes a Weekend
Perri Klass, M.D.

I wanted my mother to write this essay. My mother was a writer all her life — novels, memoirs, essays, even blog entries — and in recent years she’d written some articles about aging and illness, about the indignities of becoming less independent. So when she got sick, I decided that when she was better, I would urge her to write a piece about being in the hospital — about pain and fear and comfort and cure, but also about unexpected revelations of hospital routine and custom, as seen from the patient’s perspective. I even kept a list of topics for her, and the first one was the hospital weekend. Not too charged, I thought, not too personal — a good way to broach the subject of being a patient and to write about a practical problem while touching on the fear and pain underneath. She would write it when she was better, when she was home, when she was cured. But there was no comfort and no cure, so here I am.

From the physician’s perspective, weekends in the hospital are all about coverage. I remember, during residency, feeling that the attendings brought in doughnuts for weekend rounds because the
