Inversion-mode GaAs wave-shaped metal-oxide-semiconductor field-effect transistors (WaveFETs) are demonstrated using atomic-layer epitaxy of La₂O₃ as gate dielectric on (111)A nano-facets formed on a GaAs (100) substrate. The wave-shaped nano-facets, which are desirable for the device on-state and off-state performance, are realized by lithographic patterning and anisotropic wet etching with optimized geometry. A well-behaved 1 μm gate length GaAs WaveFET shows a maximum drain current of 64 mA/mm, a subthreshold swing of 135 mV/dec, and an IÓN/IOFF ratio of greater than 10⁷.

GaAs has been considered to replace Si in logic applications for decades due to its high electron mobility\cite{1}. To achieve high on-current surface-channel inversion-mode n-channel metal-oxide-semiconductor field-effect transistors (MOSFETs) on GaAs (100) substrate is a long-time challenge. The main obstacle is the lack of high-quality, thermodynamically stable dielectric on GaAs that can match the device criteria as SiO$_2$ on Si such as a mid-gap interface trap density ($D_{it}$) around $10^{10}$ cm$^{-2}$ eV$^{-1}$. During the past decades, tremendous efforts have been made to improve the oxide/GaAs interface with most of focus on different types of oxides and formation methods\cite{2-10}. Recent work finds that the oxide/GaAs interface quality is strongly dependent on semiconductor surface orientations. GaAs MOSFETs fabricated on (111)A surface exhibit much higher on-state current ($I_{ON}$) than other surface-orientations such as (100) and (111)B even with the same atomic-layer-deposited (ALD) oxide\cite{11}. More interestingly, much larger $I_{ON}$ can be achieved on GaAs (111)A substrate with single crystalline La-based oxide dielectrics by atomic-layer-epitaxy (ALE)\cite{12}. Mid-gap $D_{it}$ or Fermi-level-pinning problem is significantly reduced with epitaxial La$_2$O$_3$ on GaAs (111)A surface\cite{13,14}, because the number of dangling bonds are dramatically reduced due to the nature of epitaxial oxide/semiconductor interface. However, GaAs (111)A substrate is technologically less important than the widely available GaAs (100) substrate, in particular, for the development of a manufacturable device technology.

In this letter, we demonstrate GaAs wave-shaped MOSFETs (WaveFETs) on a GaAs (100) substrate by nano-engineering to form ALE La$_2$O$_3$ on (111)A nano-facets. GaAs (111)A surface is achieved on a GaAs (100) substrate by the development of an
well-controlled anisotropic wet etching process. GaAs MOSFETs are formed on wave-shaped (111)A surface channels with epitaxial La_2O_3 as dielectric. But all devices are fabricated on GaAs (100) substrates. These devices have on-state current (I_{ON}) of 64 mA/mm and transconductance (g_m) of 32 mS/mm with sub-threshold swing (SS) around 135 mV/dec. This work opens a new route to realize high-performance GaAs MOSFETs on (100) substrates potentially. The process development and deep understanding of surface chemistry on these nano-facets could also be very important for the emerging 3D III-V devices. [15-23]

Figure 1(a) and 1(b) show the schematic view and cross-sectional view of a GaAs WaveFET in this work fabricated on a semi-insulating GaAs (100) substrate with an ALE high-k dielectric. The detailed process flow is described in Figure 2(a). An HF and H_2O_2 based anisotropic wet etching process [24] was applied to form the wave structure with Ti/Au as hard mask illustrated in Figure 2(b). MOSFET fabrication starts with 2-inch semi-insulating GaAs (100) substrates. As-received wafers were first degreased by acetone, methanol and isopropanol, then wave patterns were defined by electron beam lithography and Ti/Au were deposited by electron beam evaporator. After lift-off process, periodically patterned Ti/Au strip hard masks were formed as illustrated in Figure 2(b). Then, the wafers were dipped into HF (49%): H_2O_2 (30%) (10:129) based solution to form the wave-shaped channels. (111)A surface was obtained due to the anisotropic property of the wet etching process [25]. The realization of (111)A other than (111)B is further confirmed by the electrical properties of the fabricated devices since the Fermi level on (111)B is expected to be pinned [11]. After removal of Ti/Au hard mask by KI
solution, the wafers were dipped into buffered oxide etch (BOE) for 30s and then soaked in 10% (NH₄)₂S for 15min for surface passivation. After deionized water rinse, the wafers were quickly transferred into ALD deposition chamber. 5 nm epitaxial La₂O₃ and 10 nm amorphous Al₂O₃ were then deposited by ALE/ALD. GaAs WaveFETs with 8 nm amorphous Al₂O₃ only as gate dielectric were also fabricated as the control sample. The epitaxial La₂O₃ thin films employed here were deposited from the precursors lanthanum tris(N,N'-diisopropylformamidinate) and H₂O at 385 °C , while the amorphous Al₂O₃ oxide capping layer was deposited with precursors of trimethylalumnum (TMA) and H₂O at 300 °C. The purpose of Al₂O₃ capping layer is to prevent the reaction between La₂O₃ and moisture in air and water during the process. Source and drain (S/D) regions were formed by a two-step Si implantation with dose of $1 \times 10^{14}$ cm⁻² at 30 keV and $1 \times 10^{14}$ cm⁻² at 80 keV, followed by an 850 °C rapid thermal annealing (RTA) in N₂ for 15 s. S/D ohmic contact area was first defined by e-beam lithography, and then BCl₃/Ar inductively coupled plasma (ICP) dry etching was applied to remove the Al₂O₃ and HCl wet etching was applied to remove the La₂O₃ above metal contact area. GeNiAu contact was then formed followed by a 420 °C RTA in N₂ for 15 s. Then, Ti/Au were deposited as gate electrodes and test pads. All patterns were defined by a Vistec UHR electron beam lithography system. The fabricated devices have gate lengths ($L_g$) of 1 μm, 2 μm and 4 μm.

The illustration of anisotropic wet etch process (HF and H₂O₂) is shown in Fig. 3. In this process, the wave patterned direction is critical. The wave structure has to be patterned along (01̅1) other than (011) as shown in Figure 3(a). The effect of wave
pattern direction is shown by cross-sectional scanning electron microscopy (SEM) pictures in Figure 3(b) and 3(c). Hard mask strips were patterned along (011) in Figure 3(b) and along (011) in Figure 3(c). Clear (111) surface is shown in Figure 3(b) but irregular structures are formed if hard mask strips were patterned along (011). Meanwhile, optimized WFin and WGap are also important to form compact wave structure with sharp corners so that the maximum channel width with (111)A surface can be realized within the fixed channel pitch from the top. Figure 4(a) shows the transmission electron microscopy (TEM) picture of the cross section of the wave channel. A high-resolution TEM image of the epitaxial interface, taken from a sample with 5 nm La2O3/10 nm Al2O3 as gate dielectric, is also shown in Figure 4(b). The lattice mismatch of La2O3 on GaAs (111)A is ~0.04%. It is evident that a flat and sharp interface is formed even on fabricated (111)A nano-facet. It has been proved by C-V measurement that the epitaxial La2O3/GaAs (111)A interface exhibits Dn on the order of $10^{11}$ cm$^{-2}$ eV$^{-1}$, which is far below the Dn level of traditional amorphous oxide on GaAs (111)A surface.$^{[12,13]}$ Figure 4(c) depicts the top view SEM image of one finished GaAs WaveFET with a gate length of 2 μm.

Well-behaved output, transfer and trans-conductance characteristics of a 1 μm-gate-length inversion-mode GaAs WaveFET are plotted in Figure 5, showing a maximum drain current ($I_{D,max}$) of 64 mA/mm at a gate bias ($V_{GS}$) of 4 V and a drain bias ($V_{DS}$) of 2 V, a maximum $g_m$ of 32 mS/mm at $V_{DS} = 2$ V and threshold voltage ($V_T$) of 1.32 V. SS of ~135 mV/dec is obtained with an equivalent oxide thickness (EOT) of ~6 nm, indicating a mid-gap interface trap density of $4.5 \times 10^{12}$ cm$^{-2}$ eV$^{-1}$ which is simply estimated from
equation $SS \sim 60 \times (1 + qD_{it}/C_{ox}) \text{mV/dec}$. SS could be further improved by optimizing fabrication process and reducing EOT. It will also improve the extrinsic drain current and trans-conductance by reducing the EOT of the dielectric and improving interface quality. Devices with different gate length $L_g$ (1, 2 and 4 μm) show similar SS and $V_T$ (not shown), indicating these devices are weakly affected by short channel effects. It is also expected that these GaAs devices with a large bandgap and 3D wave structures must have better immunity to short channel effects. The GaAs WaveFET with epitaxial La$_2$O$_3$ demonstrated here has $I_{D,max}$ about $1,000 \times$ larger than that of the reference GaAs sample with amorphous Al$_2$O$_3$ dielectric (not shown) and about $10,000 \times$ larger than that of GaAs planar MOSFET on GaAs (100) substrate with amorphous Al$_2$O$_3$ [11]. GaAs planar MOSFETs on GaAs (100) substrate with La$_2$O$_3$ as gate dielectric were also fabricated. Without the special surface orientation to form (111) hexagonal template, poor quality La$_2$O$_3$ dielectric was formed on GaAs (100) surface showing a weak gate modulation and minuscule $I_{D,max}$. Figure 5(d) summarizes the effective gate length $L_{eff}$ and the series resistance ($R_{SD}$) extracted by plotting $R_{tot}$ versus $L_g$, where $R_{tot}$ represents the total channel resistance measured from devices with various gate lengths under $V_{GS}$-$V_T$ from 1 to 2.5 V. $R_{SD}$ is determined to be 1.62 $\Omega \cdot$mm, which is reasonable for implanted S/D on GaAs and can be further reduced by optimizing the processes of ion implantation and activation during S/D contact fabrication. Contact resistance ($R_C$) of 0.27 $\Omega \cdot$mm is extracted from transmission line method. Two third of $R_{SD}$ is from the access resistance between Ohmic contacts to the channel underneath the gate. $\Delta L$, defined as the difference between the mask gate length $L_g$ and $L_{eff}$, is estimated to be $\sim 0.36$ μm, due to
the lateral dopant diffusion caused by high-temperature activation and/or the lithographic misalignment.

In conclusion, by realizing (111)A nano-facets on (100) surface by anisotropic wet etching and a high-quality epitaxial La$_2$O$_3$/GaAs (111)A interface by ALE, we demonstrate inversion-mode GaAs WaveFETs on GaAs (100) substrates with much larger drain currents than those formed on planar GaAs (100) surface using the same dielectric process. The work opens up a new way to improve the III-V device performance by nano-engineering semiconductor 3D structures and interfaces with high-k dielectric.

The authors would like to thank Robert M. Wallace, Andrew Kummel and John Robertson for the valuable discussions. The work at Purdue University was supported by the Air Force Office for Scientific Research, monitored by Dr. Kenneth Goretta. The work at Harvard University was performed at the Center for Nanoscale Systems, a member of the National Nanotechnology Infrastructure Network.
