Contribution of a Low-Barrier Hydrogen Bond to Catalysis Is Not Significant in Ketosteroid Isomerase

Do Soo Jang1,2,7, Gildon Choi3,7, Hyung Jin Cha1,4,7, Sejeong Shin5, Bee Hak Hong12, Hyeong Ju Lee6, Hee Cheon Lee3, and Kwan Yong Choi1,*

Low-barrier hydrogen bonds (LBHBs) have been proposed to have important influences on the enormous reaction rate increases achieved by many enzymes. Δ1,2,7-3-ketosteroid isomerase (KSI) catalyzes the allylic isomerization of Δ1,2,7-3-ketosteroid to its conjugated Δ3,4-isomers at a rate that approaches the diffusion limit. Tyr14, a catalytic residue of KSI, has been hypothesized to form an LBHB with the oxyanion of a dienolate steroid intermediate generated during the catalysis. The unusual chemical shift of a proton at 16.8 ppm in the nuclear magnetic resonance spectrum has been hypothesized to form an LBHB between Tyr14 Oδ and C3-O of equilenin, an intermediate analogue, in the active site of D38N KSI. This shift in the spectrum was not observed in Y30F/Y55F/Y115F/D38N and Y30F/Y55F/Y115F/D38N mutant KSIs when each mutant was complexed with equilenin, suggesting that Tyr14 could not form LBHB with the intermediate analogue in these mutant KSIs. The crystal structure of Y30F/Y55F/Y115F/D38N-equilenin complex revealed that the distance between Tyr14 Oδ and C3-O of the bound steroid was within a direct hydrogen bond. The conversion of LBHB to an ordinary hydrogen bond in the mutant KSI reduced the binding affinity for the steroid inhibitors by a factor of 6.1-11. In addition, the absence of LBHB reduced the catalytic activity by only a factor of 1.7-2. These results suggest that the amount of stabilization energy of the reaction intermediate provided by LBHB is small compared with that provided by an ordinary hydrogen bond in KSI.

INTRODUCTION

One of the fundamental questions in enzyme catalysis is how an enzyme can catalyze a reaction intermediate and transition state during enzymatic reaction to accelerate the enzyme-catalyzed reaction rate over the non-enzymatic one. The low-barrier hydrogen bond (LBHB) has been invoked to explain a large amount of the energy that is required to stabilize the intermediate in many enzyme reactions (Gerlt and Gassman, 1993). An LBHB has been hypothesized to occur when the distance between the two heteroatoms is less than the sum of their van der Waals radii and the pKs values of the hydrogen bond partners are similar to each other, so that they exhibit a covalent character that is absent in an ordinary hydrogen bond (Cleland and Kreevoy, 1994; Frey et al., 1994). The covalent character of LBHB could increase its strength; i.e., its ΔH of formation increase by as much as 10-20 kcal/mol (Cleland et al., 1998; Zhang, 2007). Among the conventional physicochemical parameters used to characterize LBHBs, the unusual chemical shift of proton nuclear magnetic resonance (NMR) near 16 to 20 ppm in the downfield region is regarded as the clearest evidence for the presence of LBHBs in proteins (Cleland and Kreevoy, 1994; Frey et al., 1994). However, the degree to which LBHB contributes to catalysis is controversial (Ash et al., 1997; Perrin, 2010; Pollack et al., 1999; Schultz and Warshel, 2004). A theoretical calculation led to a conclusion that LBHB cannot stabilize the transition-state more than can ordinary hydrogen bonds (Warshel and Papazyan, 1996). Experimental evidence in model compounds suggested that LBHBs might not contribute additional energy to the hydrogen bond between a hydrogen bond donor and acceptor that have matched pKs (Shan et al., 1996).

Δδ,γ-3-ketosteroid isomerase (KSI) catalyzes the allylic rearrangement of the 5,6 double bond of Δδ,γ-3-ketosteroids to the 4,5 position, and accelerates the reaction by a factor of 1011 compared to the nonenzymatic reaction by an intramolecular proton transfer (Fig. 1) (Pollack, 2004). Two bacterial KSIs, one from Comamonas testosteroni and one from Pseudomonas putida have been studied to understand the enzyme-catalyzed heterolytic C-H bond cleavage that occurs in a wide variety of biological reactions (Gerlt et al., 1991). In the reaction catalyzed by KSI, Tyr14 and Asp99 are thought to have critical functions in stabilizing a dienolate intermediate by forming LBHB or ordinary hydrogen bonds with the oxyanion of the intermediate (Cho et al., 1998; Kim et al., 1997a). The 1H NMR spectrum of
KSI complexed with equilenin (i.e., an intermediate analogue in the reaction) shows a highly deshielded proton resonance near 17 ppm, which has been regarded as compelling evidence for the involvement of LBHB in the catalysis (Cho et al., 1999; Zhao et al., 1996; 1997). NMR spectroscopic studies combined with site-directed mutagenesis have revealed that an LBHB can form between Tyr14 O and C3-O of equilenin in the active site of D38N (Ha et al., 2001). The strength of the LBHB in C. testosteroni KSI has been estimated to be at least 7.1 kcal/mol by comparing the dissociation rates of the intermediate from the Y14F and the D38N mutants (Xue et al., 1991) and by measuring the proton exchange rate of the LBHB over the pH range 4.3 to 9.0 (Zhao et al., 1996; 1997). The Y14F mutation reduced $k_{cat}$ of C. testosteroni KSI by a factor of $5 \times 10^4$ (Kuliopulos et al., 1989) but that of the D99A mutation only a factor of $5 \times 10^2$ (Wu et al., 1997). In addition, Y14F and D99A mutants of P. putida KSI (in this paper we number the residues of P. putida KSI according to those of C. testosteroni KSI) are only 1/2,000 and 1/98 times as active as the wild-type KSI (Kim and Choi, 1995; Kim et al., 1997b), respectively; this change suggests that by forming LBHBs, Tyr14 contributes to catalysis more crucially than does Asp99.

In this study, we measured the energetic difference between LBHB and the ordinary hydrogen bond in the active site of P. putida KSI. Together with the structural analyses for the hydrogen bonds involved in the catalytic reaction of P. putida KSI, our NMR spectroscopic studies revealed that the putative LBHB between Tyr14 O and C3-O of equilenin observed for D38N KSI was converted to an ordinary hydrogen bond by the Y30F/Y55F mutations. The conversion of the LBHB to an ordinary hydrogen bond resulted in only marginal effects on both catalytic activity of KSI and its binding affinity for the intermediate analogue. Our results suggest that the contribution of LBHB to catalysis should be only marginal compared with that of an ordinary hydrogen bond in the active site of KSI.

**MATERIALS AND METHODS**

**Materials**

5-androstene-3,17-dione (5-AND), androstenolone, equilenin and estrone were purchased from Steraloids Inc. (USA). $^{15}$N-Labeled NH$_4$Cl was purchased from Cambridge Isotope Laboratories Inc. (USA). A Superose 12 gel filtration column was purchased from Amersham Bioscience (USA). All chemicals for the buffer solution were purchased from Sigma (USA). All enzymes for DNA manipulation were purchased from Promega (USA). Oligonucleotides were obtained from Genotech Inc. (Korea).

**Site-directed mutagenesis, expression and purification of mutant KSIs**

Site-directed mutagenesis of Y115F, Y115F/D38N, Y30F/Y55F/Y115F, Y30F/Y55F/D38N and Y30F/Y55F/Y115F/D38N was conducted as described previously (Kim et al., 2000). All mutations were confirmed by sequencing the entire gene of the mutant KSI. Mutant KSIs were overexpressed in Escherichia coli BL21(DE3) (Novagen) harboring an expression vector plasmid containing the mutant KSI gene, and were purified as described previously (Cha et al., 2013; Jang et al., 2004). The purity of KSI was confirmed by the presence of only one band in SDS-PAGE.

**NMR spectroscopy**

NMR was performed as described previously (Jang et al., 2006). The NMR sample was adjusted to contain 15 mg/ml KSI in 40 mM potassium phosphate buffer at pH 7.0 containing 1 mM EDTA and 10% DMSO-d$_6$ (dimethyl sulfoxide-d$_6$) (v/v). NMR spectra were collected on a spectrometer (Bruker, Avance DRX500) equipped with a triple resonance, pulse field gradient probe with actively-shielded z-axis gradients, and a gradient amplifier unit. A jump-and-return pulse sequence (Plateau and Gueron, 1982) was used to suppress the water signal. The observed $^1$H chemical shifts were determined relative to that of sodium 2,2-dimethyl-2-silapentane-5-sulfonate as an internal standard.
Effects of tyrosine-to-phenylalanine substitution(s) in \( P. \ putida \) KSI on LBHB

The Y30F/Y55F/Y115F/D38N mutant KSI that contains no tyrosine residue other than Tyr14 was prepared to investigate the role of Tyr14 in the formation of LBHB without any interference from the other three tyrosines (Tyr30, Tyr55, Tyr115) in \( P. \ putida \) KSI. A highly deshielded proton resonance was not observed in the downfield region of the NMR spectrum of Y30F/Y55F/Y115F/D38N KSI complexed with equilenin (Fig. 2E), although Tyr14 still has a hydrogen bonding capability in the active site of the mutant. To determine why LBHB is absent in the Y30F/Y55F/Y115F/D38N-equilenin complex, the tyrosines at positions 30, 55, and 115 in D38N were replaced individually with a phenylalanine. The \( ^{1}H \) NMR spectra of the Y30F/D38N, Y55F/D38N, and Y115F/D38N mutants revealed that LBHB between Tyr14 O\(_{1}\) and C3-O of equilenin was not perturbed significantly by the Y30F, Y55F, or Y115F mutation (Figs. 2A, 2B, and 2C). In contrast to the single substitutions of tyrosine with phenylalanine, the highly deshielded proton resonance was not observed in the \( ^{1}H \) NMR spectrum of the Y30F/Y55F/Y115F/D38N-equilenin complex (Fig. 2D); this result indicates that the absence of LBHB in Y30F/Y55F/Y115F/D38N can be attributed to the simultaneous replacements of tyrosines with phenylalanines at the positions 30 and 55 in \( P. \ putida \) KSI.

**RESULTS**

**Affinity of steroid to KSI**

\( K_{D} \) values of KSI for equilenin and other steroid inhibitors were determined by analyzing the quenching of the intrinsic fluorescence intensity of KSI in the presence of various amounts of a steroid dissolved in DMSO. The fluorescence intensities of KSI were measured using a Cary Eclipse fluorescence spectrophotometer (Varian). The experiments were performed at 295 nm excitation and 315 nm emission. Data were fitted to the following equation:

\[
[\text{I}] = \left[ \text{F}_0 - \text{F} \right] \left( \frac{K_D}{\text{E}} + \frac{K_D}{\text{I}} \right) + \left[ \text{F}_0 - \text{F}_\infty \right],
\]

where \([\text{I}]\) is the concentration of total steroid in the solution, \( F \) is the fluorescence intensity, \( F_0 \) is the intensity in the absence of any steroid, \( F_\infty \) is the intensity in infinite steroid concentration, \( [\text{E}] \) is the concentration of KSI, and \( K_D \) is the dissociation constant.

**Determination of dissociation constants for steroid inhibitors**

The affinity of KSI for equilenin, androstenolone, or estrone was assessed by measuring the extent of quenching of intrinsic tryptophan fluorescence of KSI upon the binding of the respective steroid. The fluorescence intensities of KSI were measured with excitation at 295 nm and emission at 315 nm after adding successively various amounts of the steroid dissolved in DMSO to the solution of KSI. After correcting the data with appropriate dilution factors, dissociation constants were determined by fitting the data to the following equation:

\[
[\text{I}] = \left( \frac{[\text{I}]_0 - [\text{I}]}{K_D/\text{E} + [\text{I}]_0 - [\text{I}]_\infty} \right) + \left( \frac{[\text{I}]_0 - [\text{I}]_\infty}{K_D/\text{E} + [\text{I}]_0 - [\text{I}]_\infty} \right) + [\text{I}]_\infty,
\]

where \([\text{I}]_0\) is the concentration of total steroid in the solution, \( [\text{I}]_\infty \) is the intensity in infinite steroid concentration, \( [\text{I}]_\infty \) is the concentration of KSI, and \( K_D \) is the dissociation constant.

**Crystallization and structure determination of mutant KSIs**

Crystallization of Y30F/Y55F/Y115F/D38N KSI complexed with equilenin was conducted using a hanging drop vapor diffusion method as described previously (Cha et al., 2014; Cho et al., 1999). After 20 mg/ml of the mutant KSI was prepared in a buffer containing 40 mM potassium phosphate, pH 7.0, 1 mM EDTA, and 20 mM β-mercaptoethanol, the 70 ml of this solution was mixed with 2 μl of 10 mM equilenin in dimethyl sulfoxide. The optimized crystallization for the mutant KSI was 0.1 M sodium acetate, 3.3% methanol, and the respective amount of a steroid substrate, 5-AND. The final concentration of methanol in the reaction mixture was 3.3% by volume. All the assays were performed at 298 K. Kinetic parameters such as \( k_{cat} \) and \( K_M \) were obtained by utilizing Lineweaver-Burk reciprocal plots under the assay conditions in which the substrate concentrations were 23.3, 34.9, 58.2, 81.5, and 116.4 μM.

**Figure 2.** \( ^{1}H \) NMR spectra of \( P. \ putida \) KSIs. (A) Y30F/D38N at pH 8.5, (B) Y55F/D38N at pH 7.0, (C) Y115F/D38N at pH 8.5, (D) Y30F/Y55F/D38N at pH 8.5, (E) Y30F/Y55F/Y115F/D38N at pH 7.0. All the spectra are complexed with equilenin, respectively. The concentration of KSI is 10 mg/ml and the concentration of DMSO-d\(_6\) is 10%.
Kinetic analyses

The $k_{cat}$ and $K_M$ values of the mutant KSIs for a steroid substrate (5-AND) were compared with those of the wild type (Table 3). A previous investigation on the hydrogen bond network (Kim et al., 2000) revealed that the $k_{cat}$ values of Y30F and Y55F were decreased by factors of 1.2 and 6 respectively relative to that of the wild-type KSI. These $k_{cat}$ values are significantly lower than that of Y414F which is lower by a factor of $10^{2}$ than that of the wild-type KSI. In addition, the replacement of Tyr115 with a phenylalanine also resulted in decrease of catalytic activity by a factor of 1.5. These results indicate that Tyr30, Tyr55 and Tyr115 are not critically essential for catalysis by P. putida KSI even if the contribution of Tyr55 to catalysis is somewhat significant.

Three-dimensional structure of Y30F/Y55F/Y115F/D38N complexed with equilenin

The binding mode of equilenin in the active site of Y30F/Y55F/Y115F/D38N was investigated using X-ray crystallography. The crystals of Y30F/Y55F/Y115F/D38N-equilenin complex were found to belong to the C222₁ space group with unit cell dimensions of a = 35.2 Å, b = 95.8 Å and c = 73.5 Å. The final structure of Y30F/Y55F/Y115F/D38N-equilenin complex was determined at 2.1-Å resolution. The crystallographic statistics for the final structure are shown in Supplementary Table 1. The crystal structure of the mutant revealed that the benzyl side chains of the substituted phenylalanines were located at the positions similar to those of the corresponding tyrosine residues in D38N but without the hydroxyl groups (Fig. 4). The hydrogen bond geometry between equilenin and catalytic residues in Y30F/Y55F/Y115F/D38N was very similar to that in D38N. The bound steroid was located in the active site of the mutant KSI. In addition, the distance between Tyr14 Oᵦ and C3-O of the steroid does not exist in the active site of the mutant KSI, as revealed by NMR spectroscopic studies combined with site-directed mutagenesis (Ha et al., 2001). The absence of a highly deshielded proton resonance at ~16 ppm in the ¹H NMR spectrum of Y30F/Y55F/Y115F/D38N KSI complexed with equilenin clearly indicates that the LBHB between Tyr14 Oᵦ and C3-O of the steroid does not exist in the active site of the mutant KSI. In addition, the distance between Tyr14 Oᵦ and C3-O of equilenin was changed. The distance in the Y30F/Y55F/Y115F/D38N KSI was 2.80 Å, whereas that in D38N KSI was 2.57 Å (Fig. 4). Considering that the major features of a LBHB are a distance < 2.65 Å between a proton donor and a proton acceptor or a 16- to 20-ppm ¹H NMR chemical shift in the downfield region, or both (Frey et al., 1994; Fuhrmann et al., 2006), the putative LBHB might be replaced by an ordinary hydrogen bond in Y30F/Y55F/Y115F/D38N KSI.

Tyr14 Oᵦ forms a hydrogen bond with Tyr55 Oᵦ that is in turn hydrogen-bonded to Tyr30 Oᵦ in the active site of P. putida KSI (Fig. 1). Tyr55 may have an important function in the formation of LBHB between Tyr14 Oᵦ and C3-O of equilenin by providing a hydrogen bond to Tyr14 and consequently affecting the origin of stabilization of the reaction intermediate or the transition-state to explain the enormous rate enhancement of the enzyme-catalyzed reaction over the non-enzymatic reaction. Especially, we investigated the proposition that LBHB can provide an additional energetic contribution to enzyme catalysis compared with the ordinary hydrogen bond. In P. putida KSI, LBHB was proposed to be formed between Tyr14 Oᵦ and C3-O of equilenin, an intermediate analogue, in the active site of D38N KSI, as revealed by NMR spectroscopic studies combined with site-directed mutagenesis (Ha et al., 2001). The absence of a highly deshielded proton resonance at ~16 ppm in the ¹H NMR spectrum of Y30F/Y55F/Y115F/D38N KSI complexed with equilenin clearly indicates that the LBHB between Tyr14 Oᵦ and C3-O of the steroid does not exist in the active site of the mutant KSI. In addition, the distance between Tyr14 Oᵦ and C3-O of equilenin was changed. The distance in the Y30F/Y55F/Y115F/D38N KSI was 2.80 Å, whereas that in D38N KSI was 2.57 Å (Fig. 4). Considering that the major features of a LBHB are a distance < 2.65 Å between a proton donor and a proton acceptor or a 16- to 20-ppm ¹H NMR chemical shift in the downfield region, or both (Frey et al., 1994; Fuhrmann et al., 2006), the putative LBHB might be replaced by an ordinary hydrogen bond in Y30F/Y55F/Y115F/D38N KSI.

Tyr14 Oᵦ forms a hydrogen bond with Tyr55 Oᵦ that is in turn hydrogen-bonded to Tyr30 Oᵦ in the active site of P. putida KSI (Fig. 1). Tyr55 may have an important function in the formation of LBHB between Tyr14 Oᵦ and C3-O of equilenin by providing a hydrogen bond to Tyr14 and consequently affecting the

Three-dimensional structure of Y30F/Y55F/Y115F/D38N complexed with equilenin

The binding mode of equilenin in the active site of Y30F/Y55F/Y115F/D38N was investigated using X-ray crystallography. The crystals of Y30F/Y55F/Y115F/D38N-equilenin complex were found to belong to the C222₁ space group with unit cell dimensions of a = 35.2 Å, b = 95.8 Å and c = 73.5 Å. The final structure of Y30F/Y55F/Y115F/D38N-equilenin complex was determined at 2.1-Å resolution. The crystallographic statistics for the final structure are shown in Supplementary Table 1. The crystal structure of the mutant revealed that the benzyl side chains of the substituted phenylalanines were located at the positions similar to those of the corresponding tyrosine residues in D38N but without the hydroxyl groups (Fig. 4). The hydrogen bond geometry between equilenin and catalytic residues in Y30F/Y55F/Y115F/D38N was very similar to that in D38N. The bound steroid was located in the active site of the mutant with the steroid A-ring approaching Tyr14 and Asp99 (Fig. 4; Supplementary Fig. 1). Three catalytic residues, Tyr14, Asp38 and Asp99, which are critical for the catalytic activity of KSI, were found to be located at positions similar to those in D38N. Tyr14 Oᵦ was involved in a hydrogen bond with C3-O of equilenin with a distance of 2.80 Å in the active site of Y30F/Y55F/Y115F/D38N complexed with the steroid.

DISCUSSION

Using KSI as a model system, we investigated the nature and origin of stabilization of the reaction intermediate or the transition-state to explain the enormous rate enhancement of the enzyme-catalyzed reaction over the non-enzymatic reaction. Especially, we investigated the proposition that LBHB can provide an additional energetic contribution to enzyme catalysis compared with the ordinary hydrogen bond. In P. putida KSI, LBHB was proposed to be formed between Tyr14 Oᵦ and C3-O of equilenin, an intermediate analogue, in the active site of D38N KSI, as revealed by NMR spectroscopic studies combined with site-directed mutagenesis (Ha et al., 2001). The absence of a highly deshielded proton resonance at ~16 ppm in the ¹H NMR spectrum of Y30F/Y55F/Y115F/D38N KSI complexed with equilenin clearly indicates that the LBHB between Tyr14 Oᵦ and C3-O of the steroid does not exist in the active site of the mutant KSI. In addition, the distance between Tyr14 Oᵦ and C3-O of equilenin was changed. The distance in the Y30F/Y55F/Y115F/D38N KSI was 2.80 Å, whereas that in D38N KSI was 2.57 Å (Fig. 4). Considering that the major features of a LBHB are a distance < 2.65 Å between a proton donor and a proton acceptor or a 16- to 20-ppm ¹H NMR chemical shift in the downfield region, or both (Frey et al., 1994; Fuhrmann et al., 2006), the putative LBHB might be replaced by an ordinary hydrogen bond in Y30F/Y55F/Y115F/D38N KSI.

Tyr14 Oᵦ forms a hydrogen bond with Tyr55 Oᵦ that is in turn hydrogen-bonded to Tyr30 Oᵦ in the active site of P. putida KSI (Fig. 1). Tyr55 may have an important function in the formation of LBHB between Tyr14 Oᵦ and C3-O of equilenin by providing a hydrogen bond to Tyr14 and consequently affecting the

The proton transfer by KSI from the C4 proton of 5-AND with a perturbation (Ha et al., 2000); crystal structure of wild-type \( P. \) putida KSI complexed with deoxycholate, a competitive inhibitor of KSI, revealed that the isopentanoate moiety on the steroid D ring was involved in hydrogen bonds with the three catalytic residues, Tyr14, Asp38, and Asp99. Analysis of the hydrogen bonding geometry indicated that Asp38, for which estimated \( pK_a = 4.5 \) (Zhao et al., 1995), might be in the protonated state at pH 6.7 for the formation of the energetically favorable hydrogen bonds between the inhibitor and catalytic residues (Ha et al., 2000). Assuming that the stabilization energy of the intermediate can be significantly reduced due to the \( pK_a \) perturbation of a catalytic base (Asp38), explanation of the diffusion controlled reaction rate of KSI may not require an unusually strong interaction provided by LBHB. The nature of hydrogen bonding in the stabilization of the intermediate was investigated previously in the reaction of KSI by analyzing the binding of substituted phenols to the D38N KSI (Petrovina and Pollack, 1998). The negative charge in the D38N KSI-phenol complex was localized almost exclusively on the bound ligand, with very little charge transfer to the hydrogen bonding groups of the enzyme (Petrovina and Pollack, 1998); this localization is characteristic of ordinary hydrogen bonds. These results indicate that the ordinary hydrogen bond rather than an LBHB would be sufficient to account for the stabilization of the dienolate intermediate during the reaction of KSI.

In conclusion, we have shown that the conversion of LBHB to an ordinary hydrogen bond resulted in only marginal decrease of the catalytic activity and the binding affinity for the intermediate analogue in \( P. \) putida KSI. Our results indicate that LBHB seems to provide only moderate stabilization of the intermediate in the reaction catalyzed by \( P. \) putida KSI. Consequently, the enormous rate enhancement achieved by KSI is not attributed solely to the presence of LBHB in the active site. Rather, the enhancement may be due to the sum of many different contributions including hydrogen bonds, electrostatic and hydrophobic interactions, and positioning of the substrate on the enzyme.
