Cerebral autoregulation testing in a porcine model of intravenously administered E. coli induced fulminant sepsis
L Molnár1, M Berhes1, I Papp1, N Nemeth1, B Fulesdi1
1Deoe Aneszteziológia, Debrecen, Hungary; 1University of Debrecen, Hungary

Introduction To assess cerebral hemodynamics in an experimental sepsis model.

Methods Nineteen juvenile female Hungahib pigs were subjected into control group (n = 9) or septic group (n = 10). Under general anesthesia in animals of the sepsis group, Escherichia coli culture (2.5 × 10^5/ml; strain: ATCC 25922) was intravenously administrated in a continuously increasing manner as follows: 2 ml in the first 30 minutes, then 4 ml in 30 minutes and afterwards 16 ml/hour for 2 hours (so a total of 9.5 × 10^6 E. coli within 3 hours). In the control group the anesthesia was maintained for 8 hours, infusion was administered as a similar volume of isotonic saline solution and no other intervention was made. Hemodynamic monitoring of all animals was performed by PICCo monitoring system. The middle cerebral artery of the pigs was insonated through the transorbital window and cerebral blood flow velocity (MCAV) and pulsatility index was registered.

Results In the septic group, as expected, all animals developed fulminant sepsis and died within 3 to 7 hours two animals in 3 to 4 hours, and three in 6 to 7 hours. In the septic animals the heart rate rose and mean arterial pressure dropped, their ratio increased significantly compared with both the base values (at the 6th hour: P <0.001) and the control group (P = 0.004). The control animals showed stable condition over the 8-hour anesthesia. MCAV significantly decreased during the development of sepsis (from 23.6 ± 6.6 cm/s to 16.0 ± 3.9 cm/s, P <0.001) and pulsatility indices increased (from 0.68 ± 0.22 to 1.37 ± 0.58, P <0.01), indicating vasoconstriction of the resistance vessels. A significant relationship was fund between percent change of the MAP and the pulsatility index in septic animals (r² = 0.32) referring to maintained cerebral autoregulation.

Conclusion Cerebral autoregulation is preserved in the pig model of experimentally induced fulminant sepsis.

P2
New real-time bowel sound analysis may predict disease severity in septic patients
J Goto1, K Matsuda1, N Hari1, T Moriguchi1, M Yanagisawa1, D Harada1, T Sugawara1, O Sakata1
1University of Yamanashi School of Medicine, Chuo, Japan; 2University of Yamanashi, Kofu, Japan

Introduction Healthy bowel function is an important factor when judging the advisability of early enteral nutrition in critically ill patients, but long-term observation and objective evaluation of gastrointestinal motility are difficult. We developed a non-invasive monitoring system capable of quantifying and visualizing gastrointestinal motility in real time. In the study gastrointestinal motility was performed in patients with severe sepsis using this developed bowel sound analysis system, and the correlation between bowel sounds and changes over time in blood concentrations of IL-6, which is associated with sepsis severity, was evaluated.

Methods The study was a prospective, observational pilot study conducted in our hospital. Consecutive adult patients with severe sepsis, on a mechanical ventilator with an IL-6 blood concentration ≥100 pg/ml in the acute phase, defined as being up to the 28th day of illness in the ICU, were entered in this study between June 2011 and December 2012. Subjects were divided into those who were treated with steroids (steroid treatment group) and those who were not (no-steroids group) during the target period, because steroids strongly affect IL-6 blood levels.

Results The subjects were five adult patients in the acute phase of severe sepsis on a mechanical ventilator. Gastrointestinal motility was measured for a total of 62,399 minutes: 31,544 minutes in three subjects in the no-steroids group and 30,855 minutes in two subjects in the steroid treatment group. In the no-steroids group, the bowel sound counts were negatively correlated with IL-6 blood concentration (r = –0.76, P <0.01), suggesting that gastrointestinal motility was suppressed as IL-6 blood concentration increased. However, in the steroid treatment group, gastrointestinal motility showed no correlation with IL-6 blood concentration (r = –0.25, P = 0.27). The IL-6 blood concentration appears to have decreased with steroid treatment irrespective of changes in the state of sepsis, whereas bowel sound counts with the monitoring system reflected the changes in the state of sepsis, resulting in no correlation.

Conclusion The new real-time bowel sound analysis system provides a useful method of continuously, quantitatively, and non-invasively evaluating gastrointestinal motility in severe patients. Furthermore, this analysis may predict disease severity in septic patients.

P3
Usefulness of sepsis screening tools and education in recognising the burden of sepsis on hospital wards
EJ Galtrey, C Moss, H Cahill
Guy’s and St Thomas’ Hospitals NHS Foundation Trust, London, UK

Introduction Sepsis is defined as the presence of infection with systemic signs of infection, and severe sepsis as sepsis plus sepsis-induced organ dysfunction or tissue hypoperfusion [1]. Since the Surviving Sepsis Campaign (SSC) in 2002, the Health Service Ombudsman for England published recommendations for improving recognition and treatment of sepsis [2], the Royal College of Physicians issued a toolkit for the management of sepsis in the acute medical unit [3], and NHS England released a patient safety alert to support prompt recognition and treatment of sepsis [4]. In 2012 our Trust introduced a sepsis screening...
tool and electronic order set (EPR alert) alongside an education programme to improve delivery of the SSC bundle. Previous audits showed only 43% full bundle compliance in those that were alerted, and this raised concerns regarding the burden of unalerted sepsis. We sought to estimate the number of unalerted sepsis episodes to assess the efficacy of our screening tool and improve early recognition.

**Methods** All referrals to our critical care response team with a diagnosis of sepsis over a 3-month period (September to November 2014) were investigated to determine how many had an EPR sepsis alert comprising a prompt for blood cultures, serum lactate measurement, fluid challenge if hypotensive, and antibiotics within 1 hour.

**Results** Only 25/174 (14%) patients with a diagnosis of sepsis had an EPR sepsis alert. There was no significant difference between acute and nonacute ward areas in their likelihood of using the screening tool or alert, in contrast to previous audits of the alerted population which showed that acute areas such as A&E and medical acute admission wards had higher utilisation and bundle completion rates.

**Conclusion** Despite these interventions, most patients still do not receive the full recommended treatment bundle. These findings have prompted a point prevalence audit at ward level, which will examine all patients’ notes for the preceding 24 hours to ascertain if sepsis is truly unrecognised or whether it is simply that our current tool is not a helpful adjunct to care. With national guidelines expected within the year, we will redesign and re-launch our screening tools and education programme to improve awareness and management of this common medical emergency.

**Audit of strategies to improve sepsis management in emergency departments**

CE Thakker, T Crook, B Davies, L Mawer, T Tomouk, E Williams, G Gray, K Turner

1University of Cambridge, UK; 2Ipswich Hospital, Ipswich, UK

**Introduction** Severe sepsis results in ~36,800 UK deaths each year [1]. Prior studies demonstrate the benefit of early recognition and treatment of sepsis in reducing mortality [2]. The Sepsis Six [1] bundle aims to optimise the first hour of sepsis management. We assessed the proportion of emergency department (ED) patients with severe sepsis receiving the Sepsis Six bundle and whether this was improved by a combination of staff education and use of Sepsis Six management stickers in patient notes.

**Methods** A closed loop audit was completed in the ED at Ipswich Hospital, UK. Each cycle was 14 days with interventions made in a 4-week period between the two cycles. The interventions consisted of: Sepsis Six management stickers and posters placed in the ED; two training sessions for all ED nurses on sepsis recognition and management; a teaching session for all middle-grade doctors; and a bacterial infections. Severe sepsis is a common cause of death for the Seprisin Six. The proportion of patients with lactate ≥2 mmol/l were retrospectively reviewed. Those with ≥2 systemic inflammatory response syndrome criteria and a documented suspicion of infection were deemed to have severe sepsis. The times at which these patients had each of the Sepsis Six completed were recorded, as were the final diagnosis and 7/28 day mortality.

**Results** In Cycle 1, 31/106 patients met the criteria for severe sepsis, compared with 36/120 in Cycle 2. The delivery of the Sepsis Six interventions was highly variable. In Cycle 1 lactate levels and i.v. access had the highest 60-minute completion rates (90.3%, 83.9% respectively). Blood cultures and i.v. fluid resuscitation were completed for 61.3% and 64.5% of patients within 60 minutes. Only 38.7% of septic patients were given i.v. antibiotics within 60 minutes. In total, 58.9% of patients received antibiotics in accordance with trust guidelines. High flow oxygen, catheters and fluid balance charts had the lowest 60-minute completion rates (35.5%, 6.5%, 6.5% respectively). In Cycle 2, post intervention, there was no significant change in the percentage of patients receiving the Sepsis Six bundle.

**Conclusion** The low rates of Sepsis Six completion require improvement to meet the targets set out by the College of Emergency Medicine. Our results suggest that simple interventions are ineffective in increasing Sepsis Six completion and thus lend support to the case for integrated interventions such as electronic recording and alert systems.

**Systemic symptoms as markers for severity in sepsis**

J Edman-Waller, L Ljungstrom, R Andersson, G Jacobsson, M Werner

1Södra Alböga Hospital, Borås, Sweden; 2Skanaborg Hospital, Skövde, Sweden; 3Institute of Biomedicine, University of Gothenburg, Sweden

**Introduction** The objective of this study was to evaluate six general symptoms as markers for severe sepsis in patients with suspected bacterial infections. Sepsis is a common cause of death and morbidity. Early detection and treatment is critical for outcome. Clinical presentation varies widely and no single test is able to discriminate severe sepsis from uncomplicated infections or non-infectious emergencies. Apart from local symptoms of infection, the systemic inflammatory reaction itself may give rise to general symptoms such as muscle weakness and vomiting.

**Methods** We present an observational, consecutive study. Data from ambulance and hospital medical records were analyzed. The survey included 290 patients (mean age: 70.6 years; median age: 74 years; male: 47%) who were admitted to a 550-bed secondary care hospital, receiving intravenous antibiotics for suspected community-acquired infections. General symptoms (fever/shivering, dyspnea, muscle
weakness, gastrointestinal symptoms, localized pain, altered mental status) that were part of the reason the patient sought medical care were registered. Additionally, age, sex, vital signs, C-reactive protein, and blood cultures were registered. Patients that within 48 hours from admission fulfilled any criteria for severe sepsis were compared with patients that did not. Odds ratios for severe sepsis were computed using univariable as well as multivariable logistic regression, controlling for age and gender as confounders.

Results
Severe sepsis criteria were fulfilled in 31% \((n = 91)\) of the patients. These were older (median age: 79 years vs. 71 years) and experienced more symptoms (mean: 2.2, SD 0.9 vs. mean: 1.4, SD 0.7) than patients without severe sepsis, while there was no difference in C-reactive protein levels \((OR \leq 50 \text{ mg/l}: 1.07, 95\% \text{ CI}: 0.96 \text{ to } 1.20)\). Among individual symptoms, altered mental status \((OR: 4.4, 95\% \text{ CI}: 2.2 \text{ to } 9.0)\), dyspnea \((OR: 3.5, 95\% \text{ CI}: 2.1 \text{ to } 5.9)\), and muscle weakness \((OR: 2.2, 95\% \text{ CI}: 1.0 \text{ to } 4.4)\) were significantly related to severe sepsis. Adjusting for age and sex, altered mental status \((adj: OR: 4.1, 95\% \text{ CI}: 2.0 \text{ to } 8.4)\) and dyspnea \((adj: OR: 3.1, 05\% \text{ CI}: 1.8 \text{ to } 5.3)\) remained significant.

Conclusion
General symptoms, especially altered mental status and dyspnea, appear to be more common in severe sepsis than in milder infections. These symptoms might be utilized as a diagnostic aid for severe sepsis in the clinical setting, complementing vital signs and laboratory tests.

P8 Clinical scores and blood biomarkers for prediction of bacteremia in emergency department patients: Bacteremia Assessment in Clinical Triage (BACT) study
S Laukemann\(^1\), N Kasper\(^1\), N Kasper\(^1\), A Kutz\(^1\), S Felder\(^1\), S Haubitz\(^2\), B Müller\(^1\), P Schuetz\(^1\)
\(^1\)Kantonsspital Aarau, Switzerland; \(^2\)University Hospital, Bern, Switzerland

Introduction
Collection of blood cultures is routinely performed in patients with suspicion of infection in the emergency department (ED) despite a low yield of positive culture results. To increase sensitivity, different clinical prediction rules and blood biomarkers have been put forward. Herein, we validated the performance of different promising clinical prediction rules alone and in combination with novel blood biomarkers to predict blood culture positivity.

Methods
This is an observational cohort study including consecutive medical patients with suspected infection and collection of ED admission blood cultures. Five clinical prediction rules were calculated and admission concentrations of procalcitonin (PCT), C-reactive protein, neutrophil–lymphocyte count ratio (NLCR), lymphocyte count, white blood cell count, and red blood cell distribution width were measured. True blood culture positivity was assessed by two independent physicians. We used logistic regression models with area under the curve (AUC) to establish associations between clinical prediction rules and blood culture positivity.

Results
Of 1,083 included patients, 106 (9.8%) cultures were positive. Of the clinical prediction rules, the Shapiro rule performed best \((AUC 0.73)\) followed by the Metersky rule \((AUC 0.609)\). The best biomarkers were PCT \((AUC 0.796)\), NLCR \((0.692)\) and lymphocyte count \((AUC 0.671)\). Combination of the Shapiro rule and PCT showed the best combination \((AUC 0.822)\) and the worst was obtained for CURB-65 score \((AUC 0.7)\). The SMR for APACHE II was 0.87 and 0.85 for the SAPS III. Figure 1 shows the ROC curve for the four scores, the best observed discrimination obtained was for SAPS III score \((AUC 0.79)\) and the worst was obtained for CURB-65 score \((AUC 0.7)\). The Hosmer–Lemeshow test showed acceptable calibration for the four predictive systems \((P > 0.05)\).

Conclusion
The four analyzed scores presented good calibration, but discrimination seems better in SAPS III. Given the difficulty of calculating PSI, and its low discrimination (similar to CURB-65), we prefer to use the CURB-65 score in routine clinical practice.

P10 Predisposing factors for deep sternal wound infection after cardiac surgery
F Ampatzidou, M Sileli, A Madesis, K Antoniou, A Baddur, G Kechagioglou, T Asteni, G Drossos
General Hospital G. Papanikolaou Thessaloniki, Greece

Introduction
The aim of our study was to investigate perioperative risk factors associated with deep sternal wound infections in complicated cardiac surgery.

Methods
A total of 1,017 patients underwent cardiac surgery in a 2-year period. We investigate the correlation between deep sternal...
wound infection with the following 14 preoperative characteristics and perioperative parameters: age >75, female gender, diabetes mellitus (DM), insulin dependence, body mass index (BMI) >30, current smokers, COPD, cardiopulmonary bypass time (CBP) >120 minutes, use of steroids, emergency operation, prolonged mechanical ventilation (>48 hours), reintubation, transfusion with more than 3 units of red blood cells, and the postoperative use of non-invasive ventilation (NIV). The chi-square test was used for statistical analysis.

Results A total of 35 patients (3.44%) were complicated by deep sternal wound infections. No statistical correlation was found with age >75, gender, DM, BMI >30, steroids, emergency operation, prolonged ventilation, CBP time >120 minutes, reintubation and NIV. Factors with statistical significant correlation are presented in Table 1.

Table 1 (abstract P10)

<table>

Conclusion Postoperative deep sternal wound infections have statistical significant correlation with the following parameters: transfusion with >3 red blood cell units, history of COPD, insulin dependence and when the patient is a current smoker. Also there is a tendency for correlation with CBP time >120 minutes (P = 0.056).

P11 Risk factors for bacteremia in adult febrile patients in emergency settings
A Mikami1, Y Natori1, F Omata2, S Ishimatsu1
1St Luke’s International Hospital, Tokyo, Japan; 2St Luke’s Life Science Institute, Tokyo, Japan

Introduction Blood culture is a critical procedure for detecting potentially life threatening bloodstream infections (BSI). At the same time, an accurate diagnosis and appropriate treatment of BSI are the key factors in order to improve prognosis. The purpose of the current analysis was to identify risk factors for bacteremia in adult febrile patients in emergency settings.

Methods We conducted a retrospective case–control study within a population of adult patients visiting the emergency department at a community hospital (St Luke’s International Hospital, Tokyo, Japan) and who underwent two sets of blood culture testing between 2003 and 2012. Among a total of 13,582 patients, 1,322 (10%) were detected as bacteremia. We included in this study 179 randomly selected patients from the bacteremia group and 321 randomly selected patients from the negative blood culture group to serve as the comparison group. Multivariate logistic regression was used to evaluate the relationship between clinical characteristics factors and bacteremia.

Results In a multivariate logistic regression model, a statistically significant independent effect was found for body temperature (BT) >38°C (OR = 2.58, 95% CI, 1.76 to 3.79, P <0.001), systolic blood pressure (SBP) <100 mmHg (OR = 1.72, 95% CI, 1.11 to 2.65, P = 0.01), CRP >10 mg/dl (OR = 3.03, 95% CI, 2.05 to 4.49, P <0.001) and PaCO2 <32 mmHg (OR = 2.3, 95% CI, 1.57 to 3.37, P <0.001). Receiver operating characteristic curve analysis revealed an area under the curve value of 0.725 for differentiating patients with bacteremia from negative culture.

Conclusion BT >38°C, SBP <100 mmHg, CRP >10 mg/dl and PaCO2 <32 mmHg are independently associated with bacteremia. These factors might be useful to know whether or not adult febrile patients have bacteremia.

References
this study. Cervical spaces were subdivided into three components according to the concept of interfascial planes. The extension of acute fluid collection in cervical spaces was classified into three grades: Grade I, fluid collection confined to one component; Grade II, fluid collection spreading into two or three components; and Grade III, fluid collection spreading into four components or mediastinum. We analyzed association with CT grades and severity of illness (SOFA score, APACHE II score, CRP). All patients underwent percutaneous catheter drainage either ultrasonography guided or CT guided. We compared treatment outcome of CNF with CT grades.

Results According to elevation of CT grades, severity of illness was significantly associated with high score (APACHE II: 10.5 to 4.0, 12.8 to 4.2, 16 to 4.2, SOFA: 2.6 to 1.5, 2.9 to 1.9, 6.8 to 3.7, CRP: 17.8 to 10.6, 22.4 to 10.1, 33.3 to 11.9) and also duration of mechanical ventilation and length of hospital stay were longer (duration of mechanical ventilation: 10.9 to 6.6, 11.5 to 6.7, 15.8 to 7.2, length of hospital stay: 23.4 to 10.6, 27.9 to 21.4, 48.7 to 36.2).

Conclusion Novel classification of CNF based on CT findings showing the extension of fluid collection is a useful indicator of the disease severity and predicting clinical outcome. These findings may influence the strategy for the success of percutaneous catheter drainage.

P15 ICU mortality rates in patients with sepsis before and after the Surviving Sepsis Campaign
J Melville, S Ranjan, P Morgan
East Surrey Hospital, Redhill, UK

Introduction The aim of this study was to evaluate the effect of the Surviving Sepsis Campaign on mortality rates, before and after the second surviving sepsis publication, and to assess whether patients with sepsis being admitted to the ICU had a lower APACHE II score on admission. Patients with sepsis, who require ICU care, have an extremely poor prognosis. It has been shown that the mortality rates range from 20.7% (severe sepsis) to 45.7% (septic shock) [1]. The surviving sepsis campaign was initiated in 2002. The first, second and third publications were published in 2004, 2008 and 2012 respectively [2].

Methods A retrospective case note review was performed, looking at a sample of 5,954 patients who were 18 years or older who had been admitted to East Surrey Hospital (ESH) ICU between 1 January 2005 and 31 October 2014. The total number of patients with sepsis was 941. We compared results before and after the second publication of the surviving sepsis campaign, looking at mortality rates, age of patients, admission length prior to ICU transfer, APACHE II score and the length of stay on the ICU.

Results From the beginning of 2005 to the end of 2008, the mortality rates for septic patients was 51.9% compared with 41.3% from the beginning of 2009 to end of October 2014. Fisher’s two-tailed test showed a significant difference (P = 0.003) between the mortality before and after the second publication. The median ages before and after 2009 were 63.9 and 64.8 years. The time in hospital before admission to the ICU was greater before 2009 (6.15 days) compared with after 2009 (5.53 days). There was no significant difference (Mann–Whitney test) between the APACHE II scores, with the mean and median score the same at 17.6 and 18 for both groups. The mean length of stay was 1 day longer after 2009 (8.07 days compared with 9.07 days).

Conclusion Patients with sepsis admitted to ESH ICU had a 20% relative decrease in mortality after the second publication of surviving sepsis guidelines. The original aim of the campaign was to reduce mortality from sepsis by 25% in 5 years [3]. This decrease was not due to a significant difference between the sets of patients. The decreased time to admittance to ICU may be due to improved recognition of the need for ICU care. Overall the surviving sepsis campaign has had a significantly beneficial effect on mortality rates in patients with sepsis.

P16 Independent risk factors for long-term mortality in patients with severe infection
J Francisco, J Aragão, T Cardoso
Centro Hospitalar do Porto – Hospital Geral de Santo António, Porto, Portugal

Introduction The purpose of this study was to examine long-term mortality, 5 years after severe infection, and to identify independent risk factors associated with it.

Methods A prospective cohort study developed at a tertiary care university-affiliated 600-bed hospital including all patients with severe infection admitted into intensive care, medical, surgical, haematology and nephrology wards, over a 1-year period (2008/2009). The outcome of interest was mortality 5 years following hospitalisation and its association with specific risk factors was studied through logistic regression.

Results There were 1,013 patients included in the study. Hospital mortality rate was 14% (n = 137) and 5-year mortality was 37% (n = 379). Factors independently associated with 5-year mortality were (adjusted odds ratio (95% confidence interval)): age = 1.04 per year (1.03 to 1.05), cancer = 8.00 (3.06 to 20.88), chronic hepatic disease = 3.06 (1.06 to 8.87), chronic respiratory disease = 2.21 (1.06 to 4.62), haematologic
It is essential for existing conditions, hospital and ICU length of stay. 

Conclusions: The ICU costs of severe sepsis management significantly declined in Thailand. However, the ICU costs were a financial burden accounting for two-thirds of the hospital costs. It is essential for intensivists to contribute a high standard of care within a restricted budget. The cost-effectiveness analysis should be evaluated in sepsis care cases.

Long-term health-related quality of life in survivors of sepsis: an epidemiological study

CE Battle1,2, G Davies1, M Vijayakumar1, PA Evans1
1NISCHR HBRU Morriston Hospital, Swansea, UK; 2College of Medicine, Swansea University, Swansea, UK; 3Ed Major Critical Care Unit, Morriston Hospital, Swansea, UK

Introduction Survivors of sepsis report persistent problems that can last years after hospital discharge. The main aim of this study was to investigate long-term health-related quality of life in survivors of SIRS and sepsis compared with Welsh normative data, controlling for age, length of stay and pre-existing conditions. The second aim was to investigate any differences in long-term health-related quality of life specifically with the patients categorised into three groups: SIRS, uncomplicated sepsis, and severe sepsis/septic shock.

Methods A prospective study design was used in order to investigate all sepsis patients either presenting to the emergency department or admitted to the ICU of a regional trauma centre. A total of 106 patients were recruited and all patients were considered eligible as per the SIRS and sepsis criteria [1]. The Sepsis-related Organ Failure Assessment score was determined over the first 24 hours to assess organ function. Patients were assigned to groups as follows: sterile SIRS; uncomplicated sepsis; severe sepsis or septic shock as per the criteria. Assignment into groups was blinded and performed by an intensive care specialist independent of the study. Baseline demographics, clinical characteristics and outcomes were collected and surviving patients were sent a SF-12v2 survey at between 6 months and 2 years post hospital discharge.

Results A total of 106 patients were included in the study. A mortality rate of 34% was recorded, leading to a final response rate of 72% by the end of the data collection period. Quality of life was significantly reduced in all patients when compared with local normative data (all P <0.0001). Reductions in the physical components of health-related quality of life were more pronounced in severe sepsis/septic shock patients when compared with uncomplicated sepsis and SIRS patients.

Conclusion This is the first observational study to specifically focus on the different groups of SIRS and sepsis patients to assess long-term quality of life. Local population norms were used for comparison, rather than wide geographical norms that fail to reflect the intricacies of a country’s population. Significant reductions in quality of life were found in severe sepsis/septic shock patients compared with uncomplicated sepsis and SIRS patients, when controlling for age, pre-existing conditions, hospital and ICU length of stay.

Analysis of the mortality rate in patients admitted to the ICU for severe community-acquired pneumonia
C Joya-Montosa, MD Delgado-Amaya, H Molina-Díaz, E Curiel Balsera
Hospital Regional de Málaga, Spain

Introduction The aim of the study was to analyze the factors associated with hospital mortality in patients with severe community-acquired pneumonia (CAP) who required ICU admission.

Methods An observational, retrospective study of patients with severe CAP admitted to the ICU between January 2008 and September 2013. We analyzed clinical, epidemiological and outcome variables. Quantitative variables were expressed as the mean and standard deviation. Qualitative variables are expressed as the percentage and absolute value. We applied the Mann–Whitney and Fisher’s exact test, as needed, with an alpha error of 5%.

Results We analyzed 111 patients, 57.5 ± 17.7 years old, with 63.1% (70) males and APACHE II score on admission of 19.8 ± 17.7. ICU mortality was 29.7% (33) and in-hospital mortality was 32.4% (36). Ten percent of patients met criteria for medical care-associated pneumonia (HCAP); there were no significant differences in mortality between HCAP and CAP (P = 0.07). Patients chronically taking immunosuppressive therapy had a significantly higher mortality compared with the rest of the patients (47.8% vs. 28.4%, P = 0.07). The mortality rate was also higher in patients in whom IVF fail in the first 24 hours (42.9% vs. 17.6% with P = 0.09). Patients who required intubation and mechanical ventilation in the first 24 hours had a higher mortality rate (47.2% vs. 19%, P = 0.002). Regarding the etiology of pneumonia, in 11 patients the viral origin of infection was confirmed (10 patients had H1N1 pneumonia and one patient CMV pneumonia), with a mortality rate significantly lower than in patients with bacterial pneumonia (3.6% vs. 35.3%, P = 0.06). The use of the right antibiotic therapy at admission was associated with mortality (P = 0.0001).

Conclusion Patients admitted to the ICU with severe CAP and immunosuppressive therapy have higher mortality, with no differences between HCAP and CAP. The delay in intubation as well as bacterial and inappropriate antibiotic treatment are factors that increase mortality.

P20

Evaluation of the cost of severe sepsis and septic shock in a private ICU in Brazil
M Borges Velasco, MA Leitão, MB Leitão, DM Dalcome, LP Massete
Hospital Meridional S.A., Vila Velha, Brazil

Introduction Sepsis is a high-prevalence disease in ICUs, associated with high mortality and high costs, mainly in developing countries. The aim of this study is to demonstrate the ICU costs, in a private hospital, in patients admitted with severe sepsis and septic shock.

Methods A retrospective, observational, single-center study of patients admitted from November 2013 to March 2014 with severe sepsis and septic shock. The records data were taken from the Software Epimed, MV System, and IBM SPSS Statistics 21. The classification was based on the Surviving Sepsis Campaign 2012. We included all 50 beds of an adult ICU, clinical and surgical. All patients older than 18 years with severe sepsis and septic shock were included. We evaluated the costs of patients during their ICU stay, and its relation to clinical presentation (severe sepsis and septic shock), antibiotic start time, permanence of ICU stay, and mortality. Only the first episode per patient was recorded.

Results From November 2013 to March 2014 were included 82 patients with criteria for severe sepsis and septic shock. The mean age of patients was 62.5 ± 21.8 years, divided equally between the genres. The overall mortality rate was 34.15%. The SAPS 3 was 56.43, with death probability set to Latin America 38.83%. Patients with severe sepsis had a mortality of 23.2% and those with septic shock had a mortality rate of 58%. The average total cost during ICU admission per patient was US$57,834 and the average daily cost was US$1,641. The daily cost in patients with severe sepsis and septic shock was US$1,263 and US$2,465 (P = 0.002), respectively, and in survivors and nonsurvivors was US$1,189 and US$2,512 (P = 0.001). The length of stay of patients in the ICU was 11.09 days, being 11.3 days in patients with severe sepsis and 10.7 days in patients with septic shock (P = 0.785). The beginning of the antibiotics in nonsurvivors was 73.7 minutes and in survivors was 64.7 minutes (P = 0.757), with the earliest onset in patients with septic shock than in patients with severe sepsis (38.5 vs. 81.5 minutes, P = 0.141).

Conclusion Severe sepsis and septic shock are conditions that consume large amounts of resources. Nonsurvivors had higher average spending than survivors. Patients admitted with septic shock had higher mortality than patients with severe sepsis with high mortality in relation to the prognostic indices adopted. The beginning of the antibiotics was longer in the nonsurvivors. We should adopt measures aimed at recognizing and earlier treatment of sepsis. If we improve our treatment, especially in septic shock, we will prevent deaths and decrement costs.

Global burden of sepsis: a systematic review
C Fleischmann1, A Scherag1, NK Adhikari2, CS Hartog1, T Tsaganos1, P Schlattmann1, DC Angus3, R Reinhart1
1Jena University Hospital, Jena, Germany; 2University of Toronto, ON, Canada; 3University of Athens, Greece; 4University of Pittsburgh, PA, USA

Introduction Sepsis is a global healthcare challenge. However, comprehensive information on sepsis morbidity and mortality across the world is scarce. We aimed to estimate the global burden of sepsis and to identify knowledge gaps based on available evidence from observational epidemiological studies.

Methods We searched 15 international and national citation databases for population-level estimates on incidence rates of sepsis or severe sepsis per 100,000 person-years and case fatality rates in adult populations using consensus criteria and published in the last 40 years. No language or publication restrictions were applied. Studies were stratified into four subgroups (setting: hospital or ICU for sepsis and severe sepsis) and meta-analyzed using meta-prop of the R 3.0.2 package. Heterogeneity of the underlying effects across studies was expressed by the estimated τ, the square root of the between-study variance.

Results The search yielded 1,553 reports from 1979 to 2013, of which 37 met our criteria and 33 provided data for meta-analysis. The included studies were from 15 high-income countries in North America, Europe, Asia, and Australia. For these countries, the population incidence rate was 256 (95% CI, 182 to 360, τ = 0.43) hospital-treated sepsis cases and 151 (95% CI, 94 to 242, τ = 0.98) hospital-treated severe sepsis cases per 100,000 person-years, with large between-study heterogeneity. Restricted to the last decade, the incidence rate was 427 (95% CI, 281 to 648, τ = 0.24) sepsis cases and 331 (95% CI, 207 to 530, τ = 0.59) severe sepsis cases per 100,000 person-years. Hospital mortality was 15% for sepsis and 25% for severe sepsis during this period of time. There were no population-level sepsis incidence estimates from lower income countries. A tentative extrapolation from high-income-country data suggests global estimates of 30.7 million sepsis and 23.8 million severe sepsis cases, with potentially six million deaths each year.

Conclusion Our analyses underline the urgent need to implement global strategies to monitor sepsis morbidity and mortality – especially in low-income and middle-income countries. For further epidemiological studies, more consistent and standardized methodological approaches are needed to reduce between-study heterogeneity. In particular, further research on sepsis coding using administrative data seems necessary to derive sensitive and specific sepsis case identifications.

P22

Disparities in acute sepsis care: a systematic review
D Yaman, N Huancahuari, P Hou, J Schuur
Brigham and Women’s Hospital, Boston, MA, USA

Introduction Disparities in the incidence and outcomes of sepsis have been documented in observational studies but little is known about
how these occur and how we might prevent them. Our objective is to identify disparities by race, language, gender, socioeconomic status, insurance status and geography in acute sepsis care in emergency department (ED) or ICU settings in the published literature.

Methods We performed a systematic review of disparities in sepsis care. The search strategy and inclusion and exclusion criteria were defined a priori. A medical librarian searched the entire MEDLINE (PubMed), EMBASE and Cinahl databases prior to 2013. One author reviewed all abstracts and a second author reviewed 10% of all abstracts for agreement. Both reviewers independently reviewed each included article using an explicit study review tool. We included studies that met the following inclusion criteria: ED or ICU setting; disparities due to race, language, gender, socioeconomic status, insurance status or geography; process of care measures (antibiotics, lactate, i.v. fluid resuscitation, central line placement, vasopressor use) or outcome measures (mortality, length of stay, complications, costs). We excluded studies involving organ-specific infectious conditions, pediatric populations, case reports, and review articles.

Results We identified 778 abstracts; yielding 31 for inclusion (k = 0.95), 26 of 31 studies were excluded due to quality issues. Five articles met our inclusion criteria. Only one of the studies [1] contained data on process of care measures, showing that central venous monitoring was less likely to occur in older patients. Three studies [2-4] showed that Black patients had a higher incidence of sepsis, a higher hospitalization rate, and higher mortality rate. Plurad and colleagues [5] reported that Asian patients had increased incidence of post-traumatic sepsis. Overall, Black patients with sepsis were younger, had lower socioeconomic status and were more likely to be cared for in urban settings compared with their cohorts.

Conclusion We found little published data addressing whether disparities due to race, language, gender, socioeconomic status, insurance status or geography exist in the acute care of sepsis. As sepsis is a leading cause of in-hospital mortality, future research should determine whether such disparities exist. Specifically, prospective studies of the process of care in sepsis management may further elucidate additional factors that may contribute to these disparities.

P23 Sublingual leukocyte activation in patients with severe sepsis or septic shock
BK Fabian-Jessing,1 MJ Massey,1 MR Filbin,2 PC Hou,3 H Kirkegaard4, HE Wang5, DM Yealy,6 JA Kellum5, DC Angus,1 NJ Shapiro1
1Beth Israel Deaconess Medical Center, Boston, MA, USA; 2Massachusetts General Hospital, Boston, MA, USA; 3Brigham and Women's Hospital, Boston, MA, USA; 4Aarhus University Hospital, Aarhus, Denmark; 5University of Alabama at Birmingham, AL, USA; 6University of Pittsburgh, PA, USA

Introduction The objective of this study was to compare the number of rolling and adhered leukocytes in patients with severe sepsis/septic shock with non-infected controls. Microcirculatory flow alterations and endothelial cell dysfunction are elements of sepsis pathophysiology. Traditionally, microcirculatory emphasis has been on red blood cell vessel perfusion. However, assessment of interactions between white blood cells and endothelial cells may be another early diagnostic modality.

Methods We included adult (age >18 years) ED patients presenting with severe sepsis/septic shock (sepsis with elevated lactate (>4 mmol/l) or hypotension) from the prospective clinical ProCCESS trial. We studied a subset of patients with microcirculatory videos obtained along with non-infected control patients. Using a sidestream dark-field videomicroscope, we obtained image sequences from the sublingual mucosa and used video stabilization and frame averaging techniques to visualize slowly-moving leukocytes. We quantified the number of rolling and adhered leukocytes present per 1 mm x 1 mm visual field in a standardized 3-second clip. Furthermore, we extracted the total length of vessels candidate for counting of rolling/adhered leukocytes (vessels with an adequate focus). We report sample means with standard deviation and compare them with Student's t test.

Results We included a total of 64 patients with severe sepsis/septic shock and 32 non-infected controls. The mean number of adhered leukocytes per field in the sepsis group was 2.1 (SD 2.3) compared with 0.4 (SD 0.8) in the non-infected group (P <0.001). This corresponded to a mean number of adhered leukocytes per unit vessel length of 0.16/mm (SD 0.22) and 0.03/mm (SD 0.06) for sepsis and non-infected groups, respectively (P <0.001). For the rolling leukocytes, we observed a mean number of 27.8 (SD 19.4) in the sepsis group and 12.0 (SD 8.7) in the non-infected group (P <0.001) per field. This corresponded to a mean number of patients leukocytes per unit vessel length of 2.00mm (SD 1.67) and 0.75/mm (SD 0.55), respectively (P <0.001).

Conclusion Our results show a higher number of rolling and adhered leukocytes in patients with severe sepsis/septic shock when compared with non-infected controls. This also applies when taking the total vessel length in the field of view into consideration. This may hold potential as a useful tool in sepsis assessment.

P24 Time course of redox potential and antioxidant capacity in patients undergoing cardiac surgery
C Stoppe1, G Schaelte1, S Kraemer1, C Benstoem2, D Bar-Or3, A Goetzchenich4
1RWTH Aachen University, Aachen, Germany; 4Swedish Medical Center, Trauma Research, Englewood, CO, USA

Introduction Cardiac surgery regularly provokes inflammation and oxidative stress which contribute to the development of organ failure and mortality of patients. While the assessment of single markers does not reflect a comprehensive investigation of redox status, the measurement of oxidation–reduction potential (ORP) provides a reliable measure to assess the balance between total oxidant and antioxidant balance in the blood. The aim of the present study was to investigate the overall redox potential in patients undergoing cardiac surgery.

Methods This is a prospective observational study in patients scheduled for elective cardiac surgery. Serum samples were drawn prior to surgery, after connection to cardiopulmonary bypass (ischemia), after opening of cross-clamp (reperfusion) and after termination of surgery. The redox status of patients was measured using the bedside point of care RedoxSYS Diagnostic System™ (Luoxis, USA). Simultaneously the antioxidant capacity in serum samples were calculated in all peroperatively obtained serum samples.

Results All patients' sera (n = 17) demonstrated a significant increase of ORP upon start of myocardial ischemia (141.0 ± 4.8 mV vs. 157.9 ± 4.9 mV; P = 0.002) and compared with reperfusion (141.0 ± 4.8 mV vs. 156.7 ± 4.9mV; P <0.001, Figure 1A). In parallel, the antioxidant capacity significantly decreased during surgery (0.505 ± 0.190 μC vs. 0.384 ± 0.120 μC; P = 0.022) corresponding to the increase of oxidative stress (Figure 1B).

Conclusion This preliminary study is the first to highlight the time course of overall redox potential and antioxidant capacity in cardiac surgery patients. Further studies are underway to evaluate the clinical significance on outcome in cardiac surgery patients.
Fatty acid composition of erythrocytes in multiple organ dysfunction syndrome
A Osipenko1, A Marochkov2
1A. Kuleshov Mogilev State University, Mogilev, Belarus; 2Mogilev Regional Hospital, Mogilev, Belarus

Introduction Change in fatty acid composition of erythrocytes and blood plasma in cases of various pathological conditions is evidence of lipid metabolism disorder and can indicate the reasons for and the degree of these disorders [1]. The aim of this study was to assess the FA composition of plasma and erythrocytes in patients with multiple organ dysfunction syndrome (MODS).

Methods The objects of study were 19 people with MODS (37.6 ± 8.3 years) of various etiologies. The blood of 17 healthy volunteers aged 38.4 ± 3.3 years served as control. The FA analysis was conducted using capillary gas–liquid chromatography. Quantitative evaluation of individual FA content was made as a mass percentage of their total (C14:0 to C22:6). Statistical analysis was performed using the Mann–Whitney U test (P <0.05).

Results Our data indicate that changes in blood plasma FA composition in patients with MODS are mainly caused by activation of lipolysis in fat depots and are accompanied by an increase of monounsaturated fatty acids, a decrease in saturated stearic acid and polyunsaturated fatty acids in the ratio. In conditions of increased level of monounsaturated palmitoleic (C16:1) and oleic (C18:1) FA in blood plasma (2.53 ± 0.40% vs. 1.55 ± 0.29%, P <0.001 and 25.18 ± 2.15% vs. 16.55 ± 1.17%, P <0.001, respectively), only the level of palmitoleic (C16:1) acid is increased in erythrocytes (0.56 ± 0.12% vs. 0.16 ± 0.12%, P <0.001). Despite the high content of oleic (C18:1) acid in blood plasma in case of MODS, in erythrocytes its relative level is not changed as compared with the control group. The disorder of lipid composition constancy in erythrocyte membranes is also manifested by change in the content of saturated palmitic (C16:0) and polyunsaturated linoleic (C18:2) fatty acids. In the test group of patients, as compared with the control group there was an elevated level (27.12 ± 0.78% vs. 25.80 ±0.77%, P <0.05) of saturated palmitic (C16:0) acid combined with the reduced (11.46 ± 0.52% vs. 13.95 ± 1.09%, P <0.001) level of linoleic (C18:2) acid.

Conclusion The changes revealed in fatty acid composition of erythrocytes may indicate systemic modifications of cell membranes in MODS.

Lower platelet mitochondrial function in severe septic patients than in controls
L Lorente1, M Martín2, J Blanquer3, J Solé-Violán4, L Labarta2, C Díaz5, A Jiménez5, E López-Gallardo1, J Montoya5, E Ruiz-Pesini5
1Hospital Universitario de Canarias, La Laguna, Tenerife, Spain; 2Hospital Universitario Nuestra Señora del Prado, Santa Cruz, Tenerife, Spain; 3Hospital Cínic Universitari de Valencia, Spain; 4Hospital Universitario Dr Negrín, Las Palmas de Gran Canaria, Spain; 5Hospital San Jorge, Huesca, Spain; 6Hospital Insular, Las Palmas de Gran Canaria, Spain; 7Universidad de Zaragoza, Spain

Introduction The oxidative phosphorylation system (OXPHOS) in septic patients has been scarcely analyzed in studies of small sample size and the results are apparently inconsistent. Previously, including 96 severe septic patients, we found that nonsurviving severe septic patients showed lower platelet respiratory complex IV (CIV) activity than surviving patients at the moment of severe sepsis diagnosis and during the first week of sepsis diagnosis. However, we did not examine this enzyme activity in normal individuals. Thus, the objective of this study was to compare the CIV activity between severe septic patients and healthy control individuals in a larger series of patients (including 198 severe septic patients).

Methods This was a prospective, multicenter, observational study in six Spanish ICUs. We obtained blood samples from 198 severe septic patients at days 1, 4 and 8 of the severe sepsis diagnosis and from 96 sex-matched and age-matched healthy control individuals and determined platelet CIV activity/protein quantity. The endpoint of the study was 30-day mortality.

Results We found that severe septic patients showed lower CIV activity/protein quantity than controls at day 1 (P <0.001), day 4 (P <0.001) and day 8 (P <0.001) of severe sepsis diagnosis. Survivor severe septic patients (n = 130) showed lower CIV activity/protein quantity than controls at day 1 (P <0.001), day 4 (P <0.001) and day 8 (P <0.001) of severe sepsis diagnosis. In addition, nonsurvivor severe septic patients (n = 68) showed lower CIV activity/protein quantity than controls at day 1 (P <0.001), day 4 (P <0.001) and day 8 (P <0.001) of severe sepsis diagnosis. Besides, nonsurvivor severe septic patients showed lower CIV activity/protein quantity than survivor ones at day 1 (P <0.001), day 4 (P <0.001) and day 8 (P <0.001) of severe sepsis diagnosis.

Conclusion The major finding of our work, that represents the largest series of severe septic patients with data on OXPHOS function, was that survivor and nonsurvivor severe septic patients showed lower platelet CIV activity than healthy controls during the first week of severe sepsis diagnosis.

Influence of genetic variants in the susceptibility and outcome of influenza virus infection
J Solé-Violán1, M López-Rodríguez1, E Herrera-Ramos1, J Ruiz-Hernández1, J Horcajada2, L Borderías3, J Blanquer4, J Ferrer1, O Rajas1, J Aspa1, F Rodríguez de Castro1, C Rodríguez-Gallego1, 1Hospital GC Dr Negrín, Las Palmas de Gran Canaria, Spain; 2Hospital del Mar, Barcelona, Spain; 3Hospital San Jorge, Huesca, Spain; 4Hospital Clínico, Valencia, Spain; 5Hospital de la Princesa, Madrid, Spain

Introduction The role of genetic variability in the susceptibility and outcome of influenza virus infection (IVI) remains largely unknown. We
have previously demonstrated that variants at SFTPA2 influence the severity of H1N1pdm infection. We have now studied genetic variants at different genes, some of them previously associated with infections by influenza and/or other viruses. The purpose of this study was to analyze the role of variant genes in the susceptibility and outcome of IVI.

Methods In total, 136 white Spanish patients developed IVI (80.3% of them by H1N1pdm virus). The general population group consisted of 1,466 unrelated healthy volunteers. Patients and controls were analyzed at different polymorphisms at 13 genes (FCGR2A, FCGR3A, FCGR3B, IL1RN, IL6, LTA, TIRAP, TRL1, TRL2, TRL3, TRL4, CCR5, IGHG2).

IVI was detected in nasopharyngeal swabs using real-time PCR. The Hardy–Weinberg equilibrium was analyzed by Haploview v. 4.2. The comparisons of genotypes distribution based on susceptibility and severity were performed using the chi-squared test or Fisher’s exact test when needed. The relationship between severity in hospitalized patients and genotypes was evaluated by binary logistic regression models.

Results No associations were found between the different genetic variants and susceptibility or severity of IVI. Variants at LTA, FCGR2A, IGHG2, TRL3 and CCR5, previously associated with severity of IVI were not replicated in our study.

Conclusion Our study does not suggest that polymorphisms at LTA, FCGR2A, IGHG2, TRL3 and CCR5 genes are associated with susceptibility or severity of IVI.

P28 Phenotypic factors associated with outcome in 977 intensive care patients with faecal peritonitis: analysis of trends in the GenOSe cohort

A Tridente, G Clarke, A Walden, A Gordon, P Hutton, J Chiche, P Holloway, G Mills, J Bion, F Stuber, C Garrard, C Hinds, GenOSe Investigators
St Helens and Knowsley, Liverpool, UK

Introduction Patients admitted to intensive care following surgery for faecal peritonitis present particular challenges in terms of clinical management and risk assessment that require close collaboration between surgical and intensive care teams [1]. We aimed at establishing whether dynamic assessment of trends in selected variables may be associated with outcomes, and therefore inform medical decision-making.

Methods We analysed trends in all 35 variables available for the first week of ICU stay in 977 patients from 102 centres across 17 countries. The primary study outcome was 6-month mortality. Secondary outcomes were ICU, hospital and 28-day mortality. For each trend, Cox proportional hazards (PH) regression analyses, adjusted for age and gender, were performed for each endpoint. Trends found to be significant in these analyses, after Bonferroni correction for multiple testing, were entered into a multivariate Cox PH model, to determine independent associations with mortality.

Results The trends over the first 7 days of ICU stay (primary analysis) retained as independently associated with 6-month outcome were worsening thrombocytopenia (mortality HR = 1.02, 95% CI = 1.01 to 1.03, P < 0.001) and changes in renal function (total daily urine output HR = 1.02, 95% CI = 1.01 to 1.03, P < 0.001; renal SOFA subscore HR = 0.87, 95% CI = 0.75 to 0.99, P = 0.047), highest recorded level of bilirubin (HR = 0.99, 95% CI = 0.99 to 0.99, P = 0.02) and GCS SOFA subscore (HR = 0.81, 95% CI = 0.68 to 0.98, P = 0.028). Changes in renal function (total daily urine output and renal component of the SOFA score), GCS component of the SOFA score, total SOFA and worsening thrombocytopenia were also independently associated with secondary outcomes. Dynamic trends over the first 7 days of ICU stay in all other measured laboratory variables, physiological parameters or radiological findings failed to be retained as independently associated with outcome on multivariate analyses. Furthermore, changes in respiratory support, renal replacement therapy and inotropic and/or vasopressor requirements appeared not to be independently associated with any of the primary or secondary outcomes. Secondary post hoc analyses on trends over the first 3 and 5 days corroborated these findings.

Conclusion Only deterioration in renal function, thrombocytopenia and hyperbilirubinaemia over the first 7 days of ICU stay were consistently associated with mortality at all endpoints.

P29 Elevated basal levels of circulating activated platelets predict ICU-acquired sepsis and mortality: a prospective study

N Lavios
CHU Sint TiLMa, Liège, Belgium

Introduction Platelets are now considered to be immune and inflammatory agents as well as key cells in coagulation, and as such have been implicated in the pathophysiology of sepsis [1]. Thrombocytopenia is associated with sepsis severity and poor prognosis, and hyperactivated platelets probably contribute to microvascular thrombosis and organ failure. In the present study, we evaluated platelet activation markers as potential predictive markers of sepsis and of mortality among four commonly encountered populations of patients admitted to ICUs.

Methods Ninety-nine non-infected ICU patients were prospectively screened at day 1 (T1) and day 3 (T2) of admission after elective cardiac surgery, trauma, acute neurologic dysfunction or prolonged ventilation (>48 hours). A third sample was drawn when infection was diagnosed (T3). We evaluated platelet activation by measuring the expression of P-selectin (CD62P) and fibrinogen binding on the cell surface before and after stimulation with TRAP (thrombin receptor activator peptide) through flow cytometry. Clinical scores were obtained at admission.

Results Patients who developed sepsis (n = 18) presented with significantly higher platelet fibrinogen binding at T1 compared with patients who did not get infected (basal: P = 0.0014, upon stimulation: P < 0.005). At T1, ROC AUC for association of basal fibrinogen binding with the occurrence of sepsis was 0.79 (95% CI: 0.68 to 0.89). Elevated basal CD62P expression level was associated with increased 90-day mortality (P = 0.042, ROC AUC = 0.78 (0.64 to 0.88)). Kaplan–Meier survival curves illustrated that mortality was significantly higher after stratification based on T1 basal CD62P level (cutoff MFI > 31.56, HR = 1.36, P = 0.0007). Multivariate logistic regression analysis using clinical scores (SOFA, APACHE II, SAPS II, SAPS III) indicated that addition of CD62P level or of bound fibrinogen level significantly improved prediction of mortality (odds ratio 1.078, P = 0.003) and sepsis (odds ratio 1.033, P = 0.0012), respectively.

Conclusion Predisposition to severe infection in selected critically ill medico-surgical adults can be identified on day 1 of admission based on circulating basally activated platelets. Levels of activated platelets may add incremental prognostic information to clinical scoring.

Reference
Methods We performed a prospective observational study in patients admitted with sepsis to the mixed ICUs of two hospitals in the Netherlands between January 2011 and July 2013. Cox proportional hazards regression was used to estimate the effect of antipatelet therapy on mortality. To account for indication bias, a propensity score was constructed, and used to match antipatelet therapy users to nonusers. Plasma biomarker levels, providing insight into hallmark host responses to sepsis, including activation of endothelial cells and the cytokine network, were determined during the first 4 days after ICU admission.

Results Of 1,070 sepsis patients, 297 (27.8%) were on antipatelet therapy, including acetylsalicylic acid, clopidogrel and diprydamole, prior to ICU admission. Antipatelet users and nonusers differed significantly with regard to several baseline characteristics, such as age, gender and cardiovascular disease. Antipatelet therapy was not related to sepsis severity at presentation, the primary source of infection, causative pathogens, the development of organ failure or shock during ICU stay, or mortality up to 90 days after admission, in either the unmatched or propensity-matched analyses. Antipatelet therapy did not also modify plasma concentrations of biomarkers.

Conclusion Pre-existing antipatelet therapy does not influence clinical disease severity at presentation, nor the host response or outcome following sepsis.

P31 Perioperative programmed death-1 expression on CD4+ T cells predicts the incidence of postoperative infectious complications following gastrointestinal surgery
S Ono1, T Ikeda1, T Kubo1, H Tsujimoto2, M Kinoshita2, T Ueno1 1Hachioji Medical Center, Tokyo Medical University, Hachioji, Tokyo, Japan; 2National Defense Medical College, Tokorozawa, Saitama, Japan

Introduction Programmed death-1 (PD-1) has been reported to be an immunoinhibitory receptor expressed by chronically stimulated T cells after T-cell activation. The present study was designed to evaluate the relationship between perioperative PD-1 expression on CD4+ T cells and the incidence of postoperative infectious complications in patients undergoing gastrointestinal surgery.

Methods This was a prospective observational study. The subjects of this study included 101 patients with gastroenterological disease who underwent elective abdominal surgery via laparotomy at the National Defense Medical College Hospital. Blood samples were taken on the preoperative day (Pre) and the first postoperative day (POD1). We calculated CD4+ T-cell count and PD-1 expression on CD4+ T cells by flow cytometer. The occurrence of postoperative infectious complications was defined according to a combination of clinical findings and the results of laboratory and other tests. The postoperative infectious complications in this study included incisional surgical site infections (SSIs), organ/space SSIs, enterococcal, urinary tract infections, and pneumonia. Incisional and organ/space SSIs were diagnosed according to the definitions stated in the guidelines issued by the Center for Disease Control and Prevention.

Results Postoperative infectious complications occurred in 30 of the 101 patients. CD4+ T-cell count was significantly lower in the patients who developed postoperative infectious complications at POD1 compared with those from the patients who did not. In addition, PD-1 expression on CD4+ T cells was significantly higher at Pre or POD1 in patients who developed postoperative infectious complications. Those results were similar for the incidence of organ/space surgical site infection. Preoperative PD-1 expression on CD4+ T cells tended to be higher in males than in females. We found there was a significant negative correlation between preoperative PD-1 expression on CD4+ T cells and CD4+ T-cell count.

Conclusion Perioperative CD4+ T-cell count or PD-1 expression on CD4+ T cells could be an early predictive marker for the development of postoperative infectious complications.

P32 Mitochondrial dysfunction and ischemia in critical illness: an adipose tissue microdialysis study in 203 ICU patients
M Theodorakopoulou, S Apollonatou, N Nikitas, O Vassilakdi, A Diamantakis, V Tsagkari, F Frantzeskaki, I Dimopoulou
University Hospital of Athens, Greece

Introduction Ischemia and mitochondrial dysfunction have been implicated in critical illness. The potential of MD to diagnose and separate ischemia and mitochondrial dysfunction in ICU patients remains currently unknown.

Methods A retrospective, observational study of 203 mechanically ventilated patients studied over a 6-year period with MD including medical, surgical and trauma patients. Sepsis stages: SIRS (n = 24), severe sepsis (n = 46) and septic shock (n = 133). Median age 67 years (range: 17 to 92 years). Mortality was 53%. All subjects had a MD catheter placed in femoral adipose tissue upon admission to the ICU. Interstitial fluid samples were collected six times per day, for 3 consecutive days, and were analyzed for glucose, lactate, pyruvate, and glycerol levels. The lactate to pyruvate (LP) ratio was calculated. Blood lactate was measured. Ischemia was defined as LP ratio > 30 and pyruvate level < 70 mmol, while mitochondrial dysfunction was defined as LP ratio > 30 and pyruvate > 70 mmol.

Results Analysis during the course of the 3-day period revealed three distinct patterns: no ischemia/mitochondrial dysfunction (n = 150 or 74%), ischemia (n = 27 or 13%) and mitochondrial dysfunction (n = 26 or 13%). On day 1, median blood lactate was higher in mitochondrial dysfunction (2.2 mmol/l) compared with both ischemia (1.3 mmol/l) and with no ischemia/mitochondrial dysfunction (1.3 mmol/l) (P = 0.004). Again on day 1, median interstitial fluid lactate was higher in mitochondrial dysfunction (8.4 mmol/l), in comparison with ischemia (1.4 mmol/l) and with the group without ischemia/mitochondrial dysfunction (2.5 mmol/l) (P < 0.001). Similar results were obtained with interstitial fluid glycerol levels (P = 0.009). Median LP ratio was higher in ischemia (LP = 36), and mitochondrial dysfunction (LP = 33) compared with those without ischemia/mitochondrial dysfunction (LP = 17) (P < 0.001). Median interstitial fluid glucose was lower in ischemia (2 mmol/l) compared with both mitochondrial dysfunction (4 mmol/l) and with no ischemia/mitochondrial dysfunction (5 mmol/l) (P < 0.001). ICU mortality was 77% in mitochondrial dysfunction, 52% in ischemia and 49% in the group without ischemia/mitochondrial dysfunction (P = 0.033).

Conclusion Bedside subcutaneous adipose tissue MD is possible to diagnose and separate ischemia and mitochondrial dysfunction in general ICU patients. These two conditions are not so common; however, mitochondrial dysfunction seems to be associated with higher mortality rates.

P33 Pyruvate dehydrogenase levels are low in sepsis
E Nuazzo, X Liu, K Berg, L Andersen, M Donnino
Beth Israel Deaconess Medical Center, Boston, MA, USA

Introduction Pyruvate dehydrogenase (PDH) is a key component of aerobic metabolism. Multiple rodent studies have shown that PDH levels are low in sepsis. This leads to a shift to anaerobic metabolism, resulting in increased lactic acid. Alteration in PDH levels during sepsis; however, has never been studied in humans. The aim of this study was to identify whether PDH levels (activity and quantity) were altered in humans in sepsis.

Methods We conducted a case–control study at a single urban tertiary care center. We compared PDH levels between sepsis and healthy control subjects by measuring PDH levels in peripheral blood mononuclear cells via a novel assay. We measured PDH levels in control subjects at baseline and in sepsis subjects at 0, 24, 48 and 72 hours.

Results There were 39 sepsis (age 67 ± 14 years, M ± SD) and 19 control (age 50 ± 12 years) subjects of similar gender (56% and 63% female, respectively) and race (79% and 68% Caucasian, respectively). PDH levels in the sepsis group were significantly lower than the control
group at all time points (Figures 1 and 2). After controlling for age, gender, race, and assay plate via multivariable linear regression, the effect of treatment group remained significant. We were unable to control for comorbid illness, which was exclusively concentrated in the sepsis group.

Conclusion PDH levels are significantly lowered in humans during sepsis when compared with healthy controls, even when controlling for age, race and gender. Further research is needed to determine whether this finding persists after adjustment for comorbid disease, and whether lower PDH levels are associated with clinical outcomes.

Serial change of C1 inhibitor in patients with sepsis: a preliminary report
Th Hirose1, H Ogura1, K Jinkoo1, Y Nakamura1, H Hosotsubo1, T Shimazu1, E Kitano2, M Hatanaka2
1Osaka University Graduate School of Medicine, Suita, Japan; 2Kobe Tokiwa University, Kobe, Japan

Introduction C1 inhibitor (C1INH), belonging to the superfamily of serine protease inhibitors, regulates not only complement system, but also the plasma kallikrein–kinin system, fibrinolytic system and coagulation system. The biologic activities of C1INH can be divided into the regulation of vascular permeability and anti-inflammatory functions. In recent years, hereditary angioedema (HAE), caused by an inherited deficiency of C1INH, has been focused. During HAE attacks, vascular permeability was markedly increased, which leads to angioedema. In sepsis, significant endothelial hyperpermeability is similarly observed systemically, but the role of C1INH has not been clarified in the pathogenesis. The serial change of C1INH in patients with sepsis is not clear. The objective of this study was to clarify the serial change in C1INH in patients with sepsis and evaluate the impact of C1INH on their clinical course.

Methods We serially examined C1INH activity values (normal range 70 to 130%) and quantitative values (normal range 160 to 330 μg/ml) in patients with sepsis during the period between December 2012 and February 2013. We also analyzed their clinical course: prognosis, volume of infusion, body weight, urine volume, catecholamine administration, and steroid administration.

Results The serial change of C1INH was evaluated in five patients with sepsis (three male and two female; four survivors and one nonsurvivor; mean age, 68 ± 11 years). In the nonsurvivor, C1INH activity on admission value was 97.2% (normal range), and quantitative value was 133.1 μg/ml (below normal). In the patient with severe sepsis requiring fluid resuscitation, catecholamine and steroid administration to maintain hemodynamics, C1INH activity value on admission was 94.4% (normal range), and quantitative value was 126.7 μg/ml (below normal range). His general condition was improved on day 6, and C1INH activity value and quantitative value increased (139.9%; above normal range). In the other three patients with sepsis not requiring steroid administration, C1INH activity value on admission was 130.6 ± 8.7% (above normal range), and quantitative value was 215 ± 26.5 μg/ml (normal range).

Conclusion In the nonsurvivor or the severe patient with sepsis requiring steroid administration, the enhancement of C1INH activity was not observed, and the C1INH quantitative values were low. Further evaluation of the serial change of C1INH and the validity of C1INH replacement therapy in patients with septic shock may lead to a new strategy for management in sepsis.

P35
Expression of apolipoproteins L in neutrophils during sepsis
I Akl1, C Lelubre1, M Piagnerelli1, P Piston1, P Uzureau1, H Fayyad Kazan1, B Badran1, M Ezzedine1, K Zouaoui Boudjeltia1, L Vanhamme2, I Akl1

Introduction Sepsis is characterized by a strong systemic inflammatory reaction. The pathogenesis is driven by alterations in the immune system and is associated with high neutrophil counts related to a specific delay in apoptosis [1]. The apolipoproteins L (ApoloS) family comprises six members in humans (Apolo1 to Apol6). In light of their deregulated expression in several pathologies, they are likely to be important molecular players of programmed cell death [2]. We analyzed Apol expression in cohorts of septic and nonseptic ICU patients and healthy volunteers in order to test whether ApolS could be involved in the neutrophil apoptotic program.

Methods By means of magnetic cell sorting, peripheral neutrophils were purified from 20 healthy volunteers and 40 ICU patients with (n = 20) or without sepsis (n = 20). Apol expression was analyzed at the mRNA and protein levels by real-time PCR and western blot analysis respectively. Apoptosis of purified neutrophils was assessed using flow cytometry following 4 and 24 hours of in vitro incubation. We monitored the expression of C-reactive protein (CRP), an inflammatory marker, and its correlation with Apol expression in PMNs was studied by linear regression analysis.

Results Our results showed a significant downregulation in mRNA expression of Apol1 (P < 0.0001), Apol2 (P = 0.0009), Apol3 (P < 0.0001)
and ApoL6 (P = 0.0003) in purified PMNs from ICU patients as compared with the healthy individuals. This downregulation was also validated at the protein level for ApoL1 and ApoL2, whereas ApoL6 was upregulated in septic patients. We could not detect ApoL3 protein in any of the cohorts. This was accompanied by a significant delay in PMN apoptosis in septic patients as compared with healthy volunteers (P < 0.05) at 4 and 24 hours. We also showed a strong negative correlation in the three mixed groups between CRP and ApoL1 (R = –0.607), ApoL2 (R = –0.651), ApoL3 (R = –0.578) and ApoL6 (R = –0.506).

Conclusion: The altered apoptotic fate of neutrophils in sepsis was correlated with the modification of the expression profile of ApoLs, a family of proteins thought to be involved in the apoptotic process. The role of these proteins in the sepsis-associated phenotype of neutrophils remains to be further elucidated.

Ex vivo and in vivo generation of neutrophil extracellular traps from neutrophils from septic patients
N Takeyama, MH Huq, M Ando, T Gocho, MH Hashiba, H Miyabe, H Kano, A Tomino, M Tsuda, T Hattori, A Hirakawa
Fujita Health University, Aichi, Japan

Introduction The primary aim of this study was to determine the differences in ex vivo generation of neutrophil extracellular traps (NETs) by neutrophils from septic and nonseptic patients. We further sought to examine plasma levels of cell-free DNA (cf-DNA) and histones to assess in vivo NET formation.

Methods We isolated neutrophils from consecutive patients with sepsis (n = 17) and without sepsis (n = 18) admitted to the ICU. Neutrophils were activated by incubation with phorbol myristate acetate to induce release of NETs and NET formation was assessed by measuring the extracellular DNA level. Immunolabeling and fluorescence imaging were also performed. Extracellular killing of bacteria by NETs was studied by co-culture of Escherichia coli and neutrophils in the presence of the phagocytosis inhibitor cytochalasin D. To assess in vivo NET formation, we evaluated plasma levels of cf-DNA and histones.

Results The condition of the nonseptic patients was significantly less severe than that of the septic patients. The SOFA score of septic patients and the nonseptic patients was 6 (3 to 18) and 2.5 (1 to 8), respectively (median (IQR), P = 0.02). The overall mortality rate was 29%. After stimulation with PMA, neutrophils isolated from septic patients released 4.08 ± 1.02% of their total DNA, whereas neutrophils from nonseptic patients released 2.96 ± 2.94% (P < 0.0001). Immunofluorescent staining of released DNA, elastase, and myeloperoxidase also revealed similar results. Neutrophils from nonseptic patients showed effective extracellular killing of E. coli through NETs, whereas neutrophils from septic patients did not (P < 0.001). Plasma levels of cf-DNA and histones were higher in septic patients than in nonseptic patients (P < 0.001).

Conclusion The upregulation of immature PMN count and immature/total PMN ratio confirmed recruitment of immature neutrophils from the bone marrow into the circulation. The ex vivo generation of NETs is downregulated in neutrophils isolated from patients with sepsis. However, it is unclear whether in vivo NET formation is also impaired during sepsis, so further investigation is necessary.

Specific patterns of T-cell cytokines as an early marker of outcome in septic patients
A Franci, A Peris, F Liotta, F Annunziato, P Ruggiano, M Ferrari
A.O.U. Careggi, Florence, Italy

Introduction The inflammatory response of sepsis is developed in two phases, an inflammatory phase (SIRS) and a phase more variable in frequency and intensity (CARS): this balance has an important effect on morbidity and mortality. Lymphopenia affects particularly T cells, and correlates inversely with outcome. The aim of the study was to identify prognostic and functional early markers of T cells and NK cells related to prognosis in the septic patient population.

Methods We collected peripheral blood mononuclear cells from 47 patients with severe sepsis or septic shock at ICU admission (T0) and from 50 healthy controls. On these subjects we evaluated frequency and absolute numbers of CD4+ and CD8+ T cells and of NK and B lymphocytes, the rates of regulatory CD4+CD25+Foxp3+ T cells (Tregs), the cytotoxic potential of CD4+, CD8+ T cells and of NK cells by evaluation of perforin (PER) and granzyme (GRA) expression and production of effector cytokines (namely IL-2, IL-17, IL-4, TNFα, IFNγ) by CD4+, CD8+ T cells and NK cells upon polyclonal stimulation. The markers were compared in patients with different outcome.

Results Septic patients, compared with healthy donors, were characterized by global lymphopenia; we found increased frequencies of CD4+ T cells producing IL-2 (P = 0.0000000003), increased percentage of CD8+ T cells producing IFNγ (P = 0.03), and reduced proportion of CD4+ T cells (P = 0.000007) and NK cells (P = 0.002) producing IFNγ. We also noticed an increased frequency of CD8+ T cells expressing PER (P = 0.00000025) and GRA (P = 0.01); moreover, the proportion of NK cells expressing GRA was also significantly increased (P = 0.00019).

To establish the prognostic value of these biological markers, we compared the cytokine expression by lymphocytes in septic patients that survived with those that died (D). We found that CD4+ and CD8+ TNFα-producing T cells were significantly increased in D (P = 0.01 and P = 0.0001 respectively); similarly the percentage of CD8+ T cells producing IFNγ was more elevated in D (P = 0.006). The same was observed for IL-17 production by CD4+ T cells (P = 0.03) in D. On the contrary we observed a tendency to the reduction of circulating CD4+CD25+Foxp3+ Tregs (in D) (P = 0.08).

Conclusion Septic patients are characterized by a peculiar immunophenotype which includes global lymphopenia and a specific pattern of cytokines. Some of the evaluated markers seem to individuate those with worse outcome; in particular, this group showed an inflammatory phenotype with a higher expression of IFNγ, TNFα, IL-17 and a tendency to a reduction of Tregs.

Reduced responsiveness of blood leukocytes to lipopolysaccharide does not predict nosocomial infections in critically ill patients
LA Van Vuught, MA Weewel, AJ Hoogendijk, BP Scicluna, H Belkasim, J Horn, MJ Schultz, T Van der Poll
Academic Medical Center, Amsterdam, the Netherlands

Introduction Critically ill patients show signs of immune suppression, which is considered to increase vulnerability to nosocomial infections. Whole blood stimulation is a frequently used functional test for immune suppression. We here aimed to assess the association between whole blood leukocyte responsiveness to lipopolysaccharide (LPS) and the subsequent occurrence of nosocomial infections in critically ill patients admitted to the ICU.

Methods All consecutive critically ill patients admitted to the ICU between April 2012 and June 2013 with two or more systemic inflammatory response syndrome criteria and an expected length of ICU stay of more than 24 hours were enrolled. Age-matched and gender-matched healthy individuals were included as controls. Blood was drawn the first morning after ICU admission and stimulated ex vivo with 100 ng/ml ultrapure LPS for 3 hours. Tumor necrosis factor (TNFα), interleukin (IL)-1β and IL-6 were measured in supernatants.

Results Seventy-three critically ill patients were included, 10 of whom developed an ICU-acquired infection. Compared with healthy subjects, whole blood leukocytes of patients were less responsive to ex vivo stimulation with LPS, as reflected by strongly reduced TNFα, IL-1β and IL-6 levels in culture supernatants. However, results were not different between patients who did and those who did not develop an ICU-acquired infection (Figure 1).

Conclusion The extent of reduced LPS responsiveness of blood leukocytes in critically ill patients on the first day after ICU admission does not relate to the subsequent development of ICU-acquired infections.
E-selectin expression, indicating reduced HUVEC activation. THP-1 adhesion was substantially decreased when HUVEC were stimulated with CG300-treated plasma as compared with untreated controls.

**Methods**

Human whole blood was stimulated with LPS (100 ng/ml) from *Escherichia coli* for 4 hours. The stimulated blood or plasma from septic patients was treated in vitro with 10 vol% polystyrene-divinylbenzene (PS-DVB)-based polymers (CG161, mean pore size 16 nm; CG300, mean pore size 30 nm) or left untreated. After adsorption, the plasma was separated and diluted with cell culture medium. The resulting conditioned medium was used to stimulate human umbilical vein endothelial cells (HUVEC) for 16 hours. HUVEC activation was evaluated by the release of interleukin (IL)-1β, IL-6, IL-8, IL-10, and tumor necrosis factor (TNF)α, plasminogen activator inhibitor-1 (PAI-1), as well as the expression of intercellular adhesion molecule (ICAM)-1 and E-selectin. HUVEC were cultured at a shear stress of 5 dyne/cm² using the Ibidi perfusion system. Adhesion of monocytic THP-1 cells to HUVEC was studied after 4 hours of HUVEC stimulation with conditioned media. THP-1 cells were perfused over HUVEC at 1 dyne/cm² for 15 minutes, and adhering THP-1 were quantified over time.

**Results**

The adsorbents CG161 and CG300 substantially decreased levels of TNFα, IL-1β, IL-6, IL-8 and IL-10 in LPS-stimulated blood. TNFα, a key stimulus for HUVEC, was reduced to 12% and 8% of the initial concentration by CG161 and CG300, respectively. Stimulation of HUVEC with the adsorbent-treated plasma resulted in significantly diminished release of IL-6, IL-8, PAI-1 and decreased ICAM-1 and E-selectin expression, indicating reduced HUVEC activation. THP-1 adhesion was substantially decreased when HUVEC were stimulated with CG300-treated plasma as compared with untreated controls.

**Conclusion**

The flow model allows to study the effect of cytokine modulation on endothelial activation and to assess the interaction of activated endothelial cells with blood cells. Modulation of inflammatory mediators with porous polystyrene-based polymers attenuates endothelial activation and reduces monocyte adhesion.

**Cell-culture model to study endothelial activation in sepsis**

T Eichhorn¹, S Rauscher¹, C Hammer¹, B Führer¹, M Gröger¹, V Weber¹
¹Danube University Krems, Austria; ²Core Facility Imaging, Medical University of Vienna, Austria

**Introduction**

The endothelium is a complex organ influenced by circulating mediators, adjacent cells, physico-chemical factors, and shear stress. During systemic inflammation and sepsis, excessive and sustained activation of the endothelium result in the loss of its anti-coagulant and anti-adhesive characteristics as well as in a loss of endothelial barrier function. We set up a cell-culture model to study endothelial activation induced by lipopolysaccharide (LPS) or by plasma from septic patients and studied the effect of adsorbent-based mediator modulation on endothelial activation.

**Methods**

Human whole blood was stimulated with LPS (100 ng/ml) from *Escherichia coli* for 4 hours. The stimulated blood or plasma from septic patients was treated in vitro with 10 vol% polystyrene-divinylbenzene (PS-DVB)-based polymers (CG161, mean pore size 16 nm; CG300, mean pore size 30 nm) or left untreated. After adsorption, the plasma was separated and diluted with cell culture medium. The resulting conditioned medium was used to stimulate human umbilical vein endothelial cells (HUVEC) for 16 hours. HUVEC activation was evaluated by the release of interleukin (IL)-1β, IL-6, IL-8, IL-10, and tumor necrosis factor (TNF)α, plasminogen activator inhibitor-1 (PAI-1), as well as the expression of intercellular adhesion molecule (ICAM)-1 and E-selectin. HUVEC were cultured at a shear stress of 5 dyne/cm² using the Ibidi perfusion system. Adhesion of monocytic THP-1 cells to HUVEC was studied after 4 hours of HUVEC stimulation with conditioned media. THP-1 cells were perfused over HUVEC at 1 dyne/cm² for 15 minutes, and adhering THP-1 were quantified over time.

**Results**

The adsorbents CG161 and CG300 substantially decreased levels of TNFα, IL-1β, IL-6, IL-8, PAI-1 and decreased ICAM-1 and E-selectin expression, indicating reduced HUVEC activation. THP-1 adhesion was substantially decreased when HUVEC were stimulated with CG300-treated plasma as compared with untreated controls.

**Conclusion**

The flow model allows to study the effect of cytokine modulation on endothelial activation and to assess the interaction of activated endothelial cells with blood cells. Modulation of inflammatory mediators with porous polystyrene-based polymers attenuates endothelial activation and reduces monocyte adhesion.
Introduction
Heat shock proteins (HSPs) have intracellular cytoprotective actions, while they act extracellularly as inducers of cytokines and stimulants for immune cells during stress. Their induction constitutes a highly conserved cellular defense mechanism against all kinds of stress. Our objective was to determine the intracellular as well as extracellular levels of HSP72 and HSP90α in patients with severe sepsis (SS) or systemic inflammatory response syndrome (SIRS) admitted to a general ICU, compared with those of healthy individuals; to correlate their expression with severity of illness.

Methods
Eighty-two consecutively admitted patients in the ICU (35 SIRS; 47 SS) as well as 35 healthy controls (H) were finally enrolled in the study. Patients’ demographic characteristics, laboratory examinations and Acute Physiology and Chronic Health Evaluation (APACHE II) score were recorded on admission. HSP levels were determined intracellularly using four-color flow cytometry. Mean fluorescence intensity (MFI) values for each HSP were measured and analyzed. Extracellular levels of HSPs were determined via ELISA.

Results
HSP expression differed significantly between groups (Kruskal–Wallis), both intracellularly (HSP72 lower in SS, P < 0.001) and extracellularly (higher levels of HSP90α (P < 0.001) and HSP72 (P = 0.003) in SS). HSP72 and HSP90α intracellular expression was inversely correlated to severity of illness, as expressed by APACHE II score (Spearman’s, P = 0.003 and P = 0.025 respectively). Intracellular HSP72 was correlated to mortality when confounding factors were excluded from the analysis (logistic regression, P = 0.03). Extracellular HSP90α levels correlated with prolonged PT (P = 0.021) and INR (P = 0.008). Finally, in the SIRS group, intracellular levels of HSP90α were higher in nonsurvivors (P < 0.001).

Conclusion
SS is characterized by high levels of extracellular HSPs. Intracellular HSP72 is highly expressed during the acute phase of stress in SS, while being downregulated in SS. HSP72 and HSP90α intracellular expression and extracellular level variations correlate with severity of illness and mortality.

To evaluate the %HLA-DR expression on monocytes, the fresh whole blood was stained with anti-CD14-FITC, anti-HLA-DR-PE and CD45-PC5 while staining with anti-CD33-PE, anti-CD45-PC7, anti-hsp70-FTIC and anti-hsp90-PE allowed evaluation of the MFI expression of hsp70 on CD34⁺ monocytes. Cells were then analyzed using flow cytometry. ANOVA with post hoc tests was used to compare CD14/HLADR cell counts and hsp70 and hsp90 levels among the three groups.

Results
Nineteen controls, six SIRS patients and 25 severe sepsis patients were studied. The percent expression of HLADR on CD14⁺ monocytes was significantly different between the three groups showing progressive decrease from controls (mean 90.5 ± 3.8%) to SIRS (mean 61.2 ± 5.9%) to severe sepsis (mean 39.2 ± 5.5%) patients (controls vs. severe sepsis, P < 0.001; controls vs. SIRS, P = 0.006; SIRS vs. severe sepsis, P = 0.03). Hsp70 and hsp90 MFI were significantly different between controls (mean 49.5 ± 4.9 and 33.5 ± 3.4 respectively), SIRS (mean 69.9 ± 16.5 and 46.5 ± 5.7 respectively) and severe sepsis patients (mean 33.3 ± 4.5 and 21.7 ± 2.7 respectively) (P < 0.05 for all comparisons). Notably, the hsp level rose from controls to SIRS and fell from SIRS to severe sepsis patients. APACHE score increased significantly (P = 0.023) in septic patients compared with SIRS.

Conclusion
There were a significant difference in CD14/HLADR, a marker of immune paralysis, between controls and patients with SIRS or severe sepsis. hsp70 and hsp90 showed an initial stimulation followed by exhaustion as sepsis progressed.

This abstract is part of the study ‘Heat Shock Proteins and Glutamine Alterations Related to Hormonal, Immunological, Inflammatory and Molecular Response to Sepsis: A Combined Clinical and Experimental Study’.

Introduction
Rethinking the host’s defense mechanisms during severe infection has led to the use of flow cytometry (FCM) and to the current concept of sepsis-induced immunosuppression. However, organ dysfunctions that develop in the period preceding severe sepsis as a consequence of surgery, trauma or burn might also trigger immune reprogramming predisposing to overwhelming infection. Our aim was to look for correlation of specific phenotypes among four commonly encountered populations of patients and the later occurrence of severe sepsis and septic shock.

Methods
In total, 114 non-infected patients were prospectively screened via FCM on days 1 (T1) and 3 (T2) of elective cardiac surgery, trauma, acute neurologic dysfunction and prolonged ventilation (>48 hours). A third sample was drawn when infection was diagnosed (Tx) and 7 days later (Tx + 7). Exclusion criteria included use of immunosuppressive agent(s). The broad panel of cell-specific antibodies focused on B, T lymphocytes (Tregs, Th17, NK), NK cells, monocytes and neutrophils. Plasmatic levels of IL-2/IL-6/IL-7/TNFα/IFNy were also determined.

Results
Ninety-nine patients were included in the final analysis. Eighteen patients developed severe sepsis or septic shock. They presented with significantly higher levels of intermediate (CD14⁺/CD16⁺) and CD62L⁺ monocytes and lower IL-2 levels at T1 compared with patients who did not get septic. ROC AUC for association of these parameters with the occurrence of sepsis were 0.78 (95% CI: 0.63 to 0.91), 0.72 (0.62 to 0.82) and 0.73 (0.65 to 0.82), respectively. High counts of these monocytic cells were also associated with increased 90-day mortality (P < 0.01, ROC AUC = 0.87 (0.77 to 0.95), 0.79 (0.66 to 0.9)). Kaplan–Meier survival curves showed significantly higher mortality after stratification based on these cell counts at T1 (CD14⁺/CD16⁺: cut-off >23.6 [cells/μL, HR = 23.6 (P = 1.24 x 10⁻¹⁰)]; CD62L⁺: cut-off >95.4 [cells/μL, HR = 6.67 (P = 7.6 x 10⁻⁴)]. Multivariate logistic regression analysis using
clinical scores indicated that addition of IL-2 levels at T1 significantly improved prediction of sepsis (OR = 0.834, \( P = 0.02 \)).

**Conclusion** Predisposition to sepsis in selected critically ill medico-surgical adults can be identified on day 1 of admission based on high counts of circulating intermediate and CD62L+ monocytes and low levels of IL-2 (the latter provide incremental prognostic information). High counts of these specific monocytes correlate with higher 90-day mortality.

**Macrophage phenotype in sepsis immunosuppression**

E Theodorakis, E Diamantaki, C Tsatsanis, D Georgopoulos, K Vaporidi
University of Crete, School of Medicine, Heraklion, Greece

**Introduction** Sepsis is followed by profound, yet poorly characterized, innate immune system suppression. While low monocyte HLA-DR expression is observed in septic patients, its clinical significance has not been established [1]. *In vitro*, repeated LPS stimulation induces a tolerant or M2 macrophage phenotype, characterized by decreased cytokine production [2], which could contribute to sepsis immunosuppression. The present study examines macrophage phenotype in a mouse model and in patients with sepsis immunosuppression.

**Methods** Sepsis was induced in C57Bl6 mice by cecal ligation and puncture (CLP) followed by intratracheal instillation of *Pseudomonas aeruginosa*. Bronchoalveolar lavage fluid (BALF), cells and serum, collected 12 hours after lung infection, were analyzed for bacterial load, cytokine levels and the classical M1 marker, iNOS. Peripheral blood monocytes isolated from septic adult patients admitted to the ICU on the 1st and 7th day after admission were analyzed by flow cytometry for the expression of HLA-DR and CD86 (co-stimulatory molecule and M1 marker), and for the M2 markers, CD163 and CD206. Additional blood samples from patients and healthy volunteers were exposed *ex vivo* to LPS prior to isolation and analysis of monocyte markers.

**Results** CLP-induced sepsis resulted in immunosuppression in mice, indicated by higher BALF bacterial load after infection in CLP than in sham-operated mice, and more severe injury on histology. Serum cytokines TNF and MIP2 were greater in CLP than in sham-operated mice. Although recruitment of CD11c+ alveolar macrophages post infection was threefold greater in CLP than in sham-operated mice, those macrophages expressed 40% lower levels of iNOS. Evidence of sepsis immunosuppression was present in most patients on the 7th day after ICU admission. Low expression of CD86 and/or HLA-DR was observed in 71% of patients, and increased expression of M2 markers in 15% of patients. Upon LPS stimulation the normal decrease in M2 markers was absent in all patients on day 1, and partially restored in 50% of patients on day 7.

**Conclusion** Sepsis is associated with decreased monocyte expression of M1 markers and increased expression of M2 markers in septic mice and critically ill patients. Therefore, in addition to decreased HLA-DR expression, M2 macrophage polarization appears to be a component of sepsis-induced monocyte dysfunction, and should be considered for immune monitoring and targeted intervention.

**Expression of mRNA levels of HLA-DRA in relation to monocyte HLA-DR: a longitudinal sepsis study**

SC Cajander, ET Tina, AB Backman, AM Magnuson, KS Strålin, BS Söderquist, JK Kälman
Orebro University, Orebro, Sweden

**Introduction** Decreased monocyte surface HLA-DR (mHLA-DR) measured by flow cytometry (FCM) is an independent marker of immunosuppression in sepsis. In a previous report we demonstrated that septic patients display a strong correlation between mHLA-DR and mRNA-levels of HLA-DRA in whole blood [1]. mRNA-based HLA-DR monitoring by PCR would improve the clinical usage and facilitate conduction of multicentre studies. The primary focus in this study was to evaluate the correlation between mHLA-DR and HLA-DRA at different time points during sepsis. In addition, we assessed the dynamic expression of both mHLA-DR and HLA-DRA, in relation to sepsis severity.

**Methods** Study patients (n = 54) were included at day 1 to 2 after hospital admission if blood cultures turned positive. Repeated sampling at days 1 to 2, 3, 7, 14 and 28 was performed. mHLA-DR was monitored by FCM and HLA-DRA by quantitative RT-PCR. Mixed models for longitudinal data were used after logarithmic transformation to calculate the interactional effects of time and severity on HLA-DR expression.

---

**Figure 1 (abstract P45).** Box plots of mHLA-DR, measured by flow cytometry.

**Figure 2 (abstract P45).** Box plots of HLA-DRA, measured by qRT-PCR.
Results Correlation between mHLA-DR (FCM) and HLA-DR (PCR) at day 1 to 2 ($R = 0.78$) and day 14 ($R = 0.27$). Both HLA-DR markers increased linearly on a log scale over time. The linear association was significantly different between the severe ($n = 16$) and nonsevere septic patients ($n = 38$) when measuring either mHLA-DR (FCM) or HLA-DR (PCR). By pairwise comparison of means between the two severity groups, at every time point, the differences between groups were shown to be significant at days 1 to 2 and 3 when measuring mHLA-DR (FCM) and at days 1 to 2, 3, and 7 for HLA-DR (PCR) (Figures 1 and 2).

Conclusion The correlation between flow cytometry and PCR-based HLA-DR monitoring is stronger in the early phase of sepsis. However, the linear associations over time, in relation to sepsis severity, display similar results for both HLA-DR markers. HLA-DR (PCR) as a biomarker could be an alternative approach in monitoring immune status in sepsis but needs to be evaluated in relation to clinically relevant immunosuppression.

HLA-DR monocyte antigen expression as predictors of outcome in patients with community-acquired infections presenting with fever

D Logothetis, E Giourou, IStarakas, A Lekkiou, G Theodorou, M Leotsinidis, M Karakantza, C Gogos
University of Patras, Patra, Greece

Introduction The aim of the present study was to evaluate the prognostic value of HLA-DR antigen expression in monocytes, in patients with community-acquired infections presenting with fever, as possible markers for the patients’ final outcome.

Methods A total of 81 patients (males = 46; females = 35) presenting with fever >38°C to the emergency room (ER) of the Department of Internal Medicine of the Patras University Hospital were enrolled in the study during a period of 12 months. Sera for monocyte HLA-DR expression were obtained from the patients on admission (day 1) and on days 3, 7 or discharge/death. Results were expressed as percentages of HLA-DR-positive monocytes, calculated by the coexpression of CD14 and HLA-DR antigens in the total CD14+ population. Additionally, the patients were evaluated using the Simplified Acute Physiology Score (SAPS-II), the Sequential Organ Failure Assessment (SOFA) and the Mortality in Emergency Department Sepsis (MEDS) score on the same days while all the indicated clinical, laboratory and imaging procedures as required for fever’s differential diagnosis were followed. A questionnaire regarding demographic characteristics, comorbidities, medications used and patients’ survival was also completed. All statistical analyses were performed using SPSS v.21.

Results Lower mean HLA-DR monocyte antigen expression percentages were significantly correlated to lower Glasgow Scale scores on all days of measurement. HLA-DR expression was significantly negatively correlated to MEDS, SOFA and SAPS-II scores whereas HLA-DRA(PCR) expression was signifi cantly decreased in nonsurvivors ($n = 48$), whereas lower HLA-DR expression was correlated to longest duration of hospital stay at all time points ($P < 0.01$). Additionally, HLA-DR expression was significantly decreased in nonsurvivors ($n = 33$) compared with survivors ($n = 48$), whereas lower HLA-DR expression was correlated to longest duration of hospital stay at all time points ($P < 0.01$).

Conclusion Monocyte HLA-DR appears to be an early indicator for survival and infection progression and therefore it can be used as a predictive marker for the final outcome of patients presenting in ER departments with fever.

P47
Eosinopenia as a marker of sepsis and mortality in critically ill patients

A Savitsky, V Rudnov, V Bargin
City Clinical Hospital # 40, Yekaterinburg, Russia

Introduction The idea of using the eosinophil count (EC) as a diagnostic marker for clarifying the nature of systemic inflammatory response syndrome (SIRS) belongs to K Abidi, who showed that EC could be used as a diagnostic criterion of sepsis. There are no published data to define the role of dynamic control of EC in the process of intensive therapy as a prognostic marker and indicator of severity condition in critically ill patients. The aim was to determine the informative value of EC in the development of SIRS as a biomarker of sepsis and indicator of the severity condition and prognosis of outcome in the pathological process.

Methods A total of 143 patients were enrolled in this study who were admitted to the ICU and had SIRS. All patients were divided into a septic group – patients with community-acquired pneumonia, complicated by sepsis – and two SIRS groups of noninfectious genesis – patients who had an acute cerebrovascular accident (CVA) and an acute myocardial infarction (AMI). The absolute EC was measured at admission and in the dynamics on days 3 to 5 of stay.

Results The median EC was 75 cells/mm³ in septic patients on admission, which was significantly lower than in patients with CVA (120 cells/mm³) and AMI (130 cells/mm³). Comparison of EC in septic patients between survivors and those who died showed significant differences (Table 1). Receiver operating characteristic (ROC) analysis determined a value less than 80 cells/mm³ as the optimal diagnostic cutoff value with a high level of confidence in the comparison of septic and noninfectious groups. Area under the ROC curves was 0.94, sensitivity of 80.8%, specificity of 95.6%, $P < 0.0001$. There was a significant increase of EC in survivors, while the EC did not change significantly among those who died in the dynamics. ROC analysis determined the cutoff values of EC, which indicated a high risk of an adverse outcome in septic patients (Table 2).

Conclusion EC may be an additional diagnostic marker which characterizes the nature of SIRS. Eosinopenia associated with prognosis of outcome in critical conditions.

P48
Prevalence and clinical significance of early endotoxin activity in septic shock patients

M Bottiroli¹, R Pinciroli¹, G Monti², M Mininni³, G Casella³, R Fumagalli³
²Anestesia Rianimazione 1, A.O. Niguarda, Milan, Italy; ³Anestesia Rianimazione 1, A.O. Niguarda, Milan, Italy

Introduction The endotoxin activity (EA) assay is a useful test to risk stratify critically ill patients and assess for Gram-negative (GN) infection. However, the prevalence and significance of early high levels of EA in patients with septic shock (SS) has yet to be elucidated.
and prognostic value of the endotoxin activity assay (EAA) of sepsis in Critical Care

Introduction

Usefulness of endotoxin activity assay for early diagnosis of sepsis

P49

Methods

We designed a prospective observational study including adult patients with clinically diagnosed SS. EA was measured on arterial blood by a chemiluminescent assay within the first 24 hours from SS diagnosis. The finding of an EA value ≥0.6 was used as the cutoff for test positivity, as described elsewhere. In addition, laboratory, microbiological and clinical data were collected at inclusion. In-hospital follow-up was also conducted.

Results

A total of 107 consecutive patients were included. The overall median EA was 0.56 (0.44 to 0.71), with 46/107 (43%) patients testing positive for elevated EA (≥0.6). GN species were identified in microbial cultures as the infective etiology in 49/107 (46%) patients, of which 28 (57%) developed bacteraemia. GN infections were associated with higher levels of EA compared with other microbial causatives (0.61 (0.52 to 0.77) vs. 0.52 (0.38 to 0.64), P = 0.021). Patients with EA ≥0.6 showed significantly higher lactate levels (2 (1 to 3) vs. 3.8 (1.7 to 6.4), P = 0.01), Sequential Organ Failure Assessment (9 (6 to 12) vs. 10 (8 to 14), P = 0.04) and inotropic score (20 (5 to 50) vs. 50 (16 to 100), P = 0.003) at inclusion. See Figure 1.

Conclusion

Elevated EA is a common finding in SS patients. In patients developing SS from a GN infection, higher levels of endotoxin activity could be measured within 24 hours. Furthermore, in our study, EA ≥0.6 identified a subgroup of subjects at greater risk for worse clinical outcomes. We therefore propose use of the EA assay for the early identification and risk stratification of SS patients.

P49

Usefulness of endotoxin activity assay for early diagnosis of sepsis

S Sekine, H Imaizumi, K Masumoto, H Uchino

Tokyo Medical University, Tokyo, Japan

Introduction

The purpose of this study was to evaluate the diagnostic and prognostic value of the endotoxin activity assay (EAA) of sepsis in patients with systemic inflammatory response syndrome (SIRS) and organ failure in ICU setting.

Methods

In total, 76 patients with SIRS and organ failure or who were suspected of sepsis during critical care were included. According to the levels of EAA, all patients were classified into three groups (group L, EAA <0.4; group M, EAA ≥0.4 or EAA <0.6; group H, EAA ≥0.6). In order to evaluate the severity of illness, the Acute Physiology and Chronic Health Evaluation II (APACHE II) score, Sequential Organ Failure Assessment (SOFA) score and catecholamine (CA) index were recorded. Blood samples were obtained to measure EAA levels, inflammatory markers (procalcitonin, C-reactive protein and white blood cells), serum lactate level as an indicator of tissue hypoxia, and for blood culture. All patients were followed up for 6 months. APACHE II score, SOFA score, CA index, inflammatory markers, serum lactate levels and blood culture results were examined for diagnosis of sepsis, severe sepsis, septic shock and for prognosis of 30-day mortality. Each value was also compared with EAA levels.

Results

Patient age was 69 ± 9.9 years (male: n = 48, female: n = 25). The total number of samples was 106 (group L/group M/group H: 35/35/36). Twenty-seven specimens were obtained from nonseptic patients and 83 specimens were obtained from septic patients. APACHE II score was highly correlated with SOFA score (P <0.05). In group H, the APACHE II score was significantly higher (22.2 ± 0.8) than that in group M (18.4 ± 0.87) (P = 0.01). The SOFA score in group H was significantly higher (9.9 ± 0.5) than that in group M (7.5 ± 0.6) and group L (7.9 ± 0.6) (P = 0.006). EAA levels were significantly increased in septic patients (septic patients: 0.56 ±0.03, nonseptic patients: 0.42 ±0.05) (P = 0.01) and in the positive blood culture group (positive group: 0.66 ± 0.05, negative group: 0.48 ± 0.03) (P = 0.006). There was no relationship between EAA levels and other inflammation markers or 30-day mortality.

Conclusion

In patients with suspected sepsis and positive blood culture, EAA levels were significantly increased and had strong correlation with severity of disease. This result suggests that EAA indicates the state of sepsis regardless of the possibility of infection in patients with SIRS with organ failure.

Biomarkers in sepsis: a systematic review

F Marniello1, J Marshall2

1Institute of Medical Sciences, Toronto, ON, Canada; 2St. Michael’s Hospital, Toronto, ON, Canada

Introduction

Sepsis is a common reason for admission to ICUs throughout the world. During the past two decades, the incidence of sepsis in the USA has tripled and is now the 10th leading cause of death. As sepsis continues to impact negatively on critically ill patients, it is clear that early diagnosis and effective management could improve patient morbidity and mortality. Numerous studies have attempted to examine biomarkers and their ability to diagnose and prognosticate septic patients. Despite multiple efforts, currently there are no reliable markers that can effectively improve our clinical effectiveness in diagnosing and managing septic patients. The purpose of our systematic review was to evaluate the diagnostic and prognostic value of various biomarkers used in septic patients.

Methods

A systematic search of the literature was performed with MEDLINE, EMBASE, and the Cochrane Central Register of Controlled Trials databases using terminology selected for biomarkers (through to and including November 2013). All articles involving neonates and not in English were excluded. Inclusion was agreed on by two independent reviewers of abstracts or full text. Assessment was based on the biomarker’s ability to diagnose septic patients and its ability to predict mortality.

Results

Of 5,257 articles identified, all abstracts were screened, and 750 full-text articles were selected for review. These included primarily randomized controlled trials, cohort studies and postmortem studies. Of 49 biomarkers examined, 72% of the studies examined procalcitonin. Comparing the serum of septic patients with that of controls, most biomarkers were elevated in septic patients, even though only a few had high sensitivity (>85%) and high specificity (>80%). It was often
difficult to compare study group with control group as the control group patients were usually not healthy controls.

**Conclusion** Overall the heterogeneity of studies, small sample size and the lack of true healthy controls influenced the ability to use the biomarker for prognostication of a septic patient. Furthermore, the lack of healthy control raises the question of redefining selection criteria in order to better study septic patients.

**C-reactive protein and hemogram parameters for the nonsepsis SIRS and sepsis: what do they mean?**

B Guçyetmez1, HK Atalani1, M Berktas1, E Özdem1, N Çakar1
1International Hospital, Istanbul, Turkey; 2Atasehir Memorial Hospital, Istanbul, Turkey; 3Kappa Consulting, Istanbul, Turkey; 4Antalya Memorial Hospital, Antalya, Turkey; 5Acibadem University, Istanbul, Turkey

**Critical Care 2015, 19(Suppl 1):**PS1 (doi: 10.1186/cc14131)

**Introduction** The aim of this study was to investigate the laboratory parameters as an indicator of sepsis. Sepsis is one of the most common reasons of mortality and morbidity in the ICU [1]. Thus, it is important to distinguish sepsis from nonsepsis SIRS. CRP and hemogram parameters may be fast, easy and affordable alternatives in distinguishing sepsis from nonsepsis SIRS. Eosinophil count (EoC), lymphocyte count (LymC) and neutrophil–lymphocyte count ratio (NLCR) are used as sepsis indicators [1,2].

**Methods** A total of 2,777 patients admitted to the ICU of two centers between 2006 and 2013 were evaluated retrospectively. The patients were diagnosed as SIRS(-), nonsepsis SIRS or sepsis at ICU admission by the consensus of two doctors in accordance with 1992 sepsis guidelines [3]. The patients who were under 18 years old, readmitted, immunosuppressive, SIRS(-) and whose laboratory values and outcomes were unknown were excluded. In total, 1,302 patients were divided into two groups as the nonsepsis SIRS group and the sepsis group. The patient’s age, gender, diagnoses (medical, elective and urgent surgery), APACHE II, SOFA, CRP, WBC, neutrophil count (NeuC), LymC, NLCR, EoC, platelet, mean platelet volume, length of ICU stay and mortality were recorded by a third doctor. In the fully adjusted model, WBC, CRP, LymC, NeuC, NLCR and EoC were entered into the model.

**Results** A total of 1,302 patients were categorized as nonsepsis SIRS (816, 62.7%) and sepsis (486, 37.3%). In the sepsis group, age, APACHE II, SOFA, mortality, length of ICU stay, CRP, NLCR and EoC were higher; LymC was lower than in the nonsepsis SIRS group (P <0.001 for each). Likelihood of sepsis (reference to nonsepsis SIRS) increased 2.62 (2.05 to 3.34), 2.02 (1.42 to 2.88) and 1.88 (1.36 to 2.60) times (OR (95% CI)) respectively in mutually adjusted multivariate logistic regression (P <0.001 for each).

**Conclusion** CRP, LymC and NLCR may distinguish sepsis from nonsepsis SIRS. Thus, CRP and hemogram parameters may contribute to early diagnosis of sepsis.

**Serum cholinesterase activity as an early indicator of systemic inflammation**

AR Zivkovic1, K Schmidt1, J Bender1, T Brenner1, S Hofer2
1Heidelberg University Hospital, Heidelberg, Germany

**Critical Care 2015, 19(Suppl 1):**PS2 (doi: 10.1186/cc14132)

**Introduction** Early diagnosis of systemic inflammation, a generalised response to noxious stimuli, is fundamentally important for effective and goal-directed therapy. Various inflammation biomarkers have been used in clinical and experimental practice. However, a definitive diagnostic tool for an early detection of systemic inflammation remains to be identified. Acetylcholine (Ach) has been shown to play an important role in the inflammatory response. Serum cholinesterase (butyrylcholinesterase (BChE)) is the major Ach hydrolyzing enzyme in plasma. The role of this enzyme during inflammation has not yet been fully understood. Here, we describe a correlation between the BChE activity and the early systemic inflammatory response upon traumatic injury.

**Methods** We measured BChE activity in patients with traumatic injury admitted to the emergency room using a point-of-care-test (POCT) system. In addition, we measured levels of routine inflammation biomarkers during the initial treatment period. We used the Injury Severity Score to assess the trauma severity. Data were statistically analyzed using the Friedman test. Correlation analysis was performed using Spearman’s rank correlation test. P <0.05 was considered statistically significant.

**Results** Reduced BChE activity correlated with trauma severity and the resulting systemic inflammation. Compared with serum levels of routinely measured inflammatory biomarkers, changes in the BChE activity were detected significantly earlier, suggesting that the BChE activity might serve as an early indicator of systemic inflammation.

**Conclusion** Our results suggest that BChE activity, measured using a POCT system, might play an important role in the early diagnosis of trauma-induced systemic inflammation.

Sphingosine-1-phosphate is a new biomarker for severity in human sepsis

MS Winkler1, A Nierhaus1, E Mudersbach1, M Holzmann1, A Bauer1, L Robbe1, C Zahrte1, G Daum1, S Kluge1, C Zoeller1

1University Medical Center Eppendorf, Hamburg, Germany; 2University Heart Center, Hamburg, Germany

Introduction During sepsis a leading symptom is capillary leakage caused by endothelial damage, followed by multiorgan dysfunction. Sphingosine-1-phosphate (S1P) is a bioactive lipid with multiple functions. Cellular reactions depend on the S1P concentration in the blood and its binding to five specific G-protein coupled receptors. S1P-regulated functions include: control of endothelial permeability; lymphocyte migration across microvessels depending on an S1P gradient; and control of vascular tone [1]. This study will address the question of whether S1P blood concentrations are associated with sepsis severity.

Methods Following ethical approval we enrolled patients fulfilling the ACCP/SCCM sepsis criteria into three groups (Group A: sepsis; Group B: severe sepsis; Group C: septic shock). A group of 20 healthy donors served as controls. Laboratory data and clinical parameters are presented for day 1. The primary outcome variable was serum S1P concentration (μg/l) quantified by mass spectrometry (Agilent®). The SOFA score was used to describe disease severity.

Results We included 87 patients (32 Group A, 25 Group B, 30 Group C). The serum concentration of S1P (mean ± SD) in the control group was 484.6 ± 152.6 μg/l and significantly higher compared with Group A 239.4 ± 61.3 μg/l, Group B 248.6 ± 93.7 μg/l and Group C 141.6 ± 46.3 μg/l. We observed a negative correlation between S1P and SOFA score (Pearson r = –0.45, P < 0.001, R = 0.2). The median SOFA score in our cohort was 6. We divided the cohort into two groups: SOFA score <6; and SOFA score >6. The sensitivity and specificity of S1P to indicate disease severity by ROC analysis. In our cohort the area under the curve (AUC) for S1P was 0.77 (CI 0.670 to 0.870) and therefore higher when compared with common markers of inflammation (PCT, IL-6, CRP) and procalcitonin (PCT) levels, in early sepsis.

Conclusion Our findings suggest that S1P is a novel marker for severity of sepsis with severe sepsis and septic shock being associated with low levels of S1P. Moreover, blood concentrations of S1P might play a key role in sepsis pathophysiology.

Diagnostic accuracy and clinical relevance of an inflammatory biomarker panel in early sepsis in adult critical care patients

P Bauer1, R Kashyap2, S League, J Park, D Block, N Baumann, A Algeciras-Schimnich, S Jenkins, C Smith, O Gajic, R Abraham

Mayo Clinic, Rochester, MN, USA

Introduction Low awareness, late recognition and delayed treatment of sepsis are still common. CD64 is a marker of the innate immune response upregulated in sepsis. The primary goal of this prospective, double-blind study was to (a) compare the diagnostic accuracy of neutrophil CD64 and other cellular markers, along with C-reactive protein (CRP) and procalcitonin (PCT) levels, in early sepsis.

Methods Adult ICU patients, between 2012 and 2014 were eligible. The eight-color flow cytometric biomarker panel included CD64, CD163, HLA DR, CD15 and others. Diagnostic test results were compared with infection as the reference standard and sepsis as the target condition, using receiver operating characteristic curve analyses. Multivariable logistic regression was used to assess the relationship of sets of markers with the probability of sepsis, adjusting for other patient characteristics.

Results A total of 303 patients were included over a 6-month period (60.4% male, median age 65.2 years). The correlation between capillary or venous blood samples with a measuring range of 0.1 to 10.0 μg/l.

Conclusion Procalcitonin (PCT) is increasingly the standard in the emergency department (ED) for the diagnostic and prognostic workup of patients with suspected infections. Recently, B·R·A·H·M·S PCT direct, a new high-sensitive point-of-care test, has been developed for fast PCT measurement on capillary or venous blood samples with a measuring range of 0.1 to 10.0 μg/l.

Methods This is a prospective, comparative international study conducted in three European EDs. Consecutive patients with suspicion of bacterial infection were included. Duplicate determination of PCT was performed on two distinct B·R·A·H·M·S PCT direct test devices on capillary (fingertip) and venous whole blood (EDTA), and compared with the reference method (B·R·A·H·M·S PCT sensitive Kryptor or Elecsys B·R·A·H·M·S PCT, respectively). The diagnostic accuracy was evaluated by correlation and concordance analyses.

Results A total of 303 patients were included over a 6-month period (60.4% male, median age 65.2 years). The correlation between capillary or venous whole blood and the reference method was excellent: r² = 0.96 and 0.97, sensitivity 88.1% and 93.0%, specificity 96.5% and 96.8%, concordance 93% and 95% respectively at a 0.25 μg/l threshold. No significant bias was observed (−0.04 and −0.02 for capillary and venous whole blood) although there were 6.8% and 5.1% outliers, respectively. B·R·A·H·M·S PCT direct had a shorter time to result as compared with the reference method (25 vs. 147 minutes, difference 122 minutes, 95% CI = 110 to 134 minutes, P < 0.0001).

Conclusion This study found a high diagnostic accuracy and a faster time to result of the PCT direct in the ED setting. The B·R·A·H·M·S PCT direct may allow a more widespread use of PCT tests in outpatient clinics and smaller institutions.

Serum procalcitonin level correlates with endotoxin activity in patients with septic shock

P Adamik, J Smienowicz, D Jakuczyk, B Adamiczkwa-Ciszewicz, T Kaiser, A Küberl

Medical University, Wroclaw, Poland

Introduction Endotoxin, a key component on the outer membrane of Gram-negative bacteria, is considered to be the most important toxin
involved in the development of septic shock, and procalcitonin (PCT) serum concentration has been strongly associated with the severity of sepsis. The effect of elevated endotoxin activity (EA) on PCT serum level, organ function and mortality of patients with septic shock was evaluated on the day of admission to the ICU.

**Methods** ICU patients with diagnosis of septic shock were consecutively added to the study group within the first 24 hours. Serum PCT level and whole blood EA was immediately measured in all patients on admission (n = 157). Endotoxemia was defined as EA >0.4 EAU.

**Results** Endotoxemia was present in 61% of patients (group 1, n = 95, age 66 (57 to 75)), and in 39% of patients EA was low (group 2, n = 62, age 63 (55 to 76)). Median EA was 0.57 EAU (0.46 to 0.67) in group 1 and 0.27 EAU (0.17 to 0.36) in group 2 (P <0.001). The PCT level was six times higher in group 1 than in group 2 (19.6 ng/ml vs. 3.1 ng/ml, P <0.001) and was correlated with EA (P <0.01, R = 0.5). Median APACHE II score was 23 points (16 to 29) in group 1 and 19 (16 to 25) in group 2; but observed difference was not significant. The severity of clinical status estimated by SOFA score was similar in both groups (10 (7 to 13) in group 1 and 11 (8 to 12) in group 2; NS). Forty-six percent of patients in group 1 and 27% in group 2 required renal replacement therapy (P = 0.01). ICU mortality of patients was 41%. The mortality rate was higher in group 1, compared with group 2, and Kaplan–Meier survival analysis-plot (log-rank test) analysis showed statistical significance between the two groups (P = 0.001, log-rank test). A Gram-negative pathogen as the primary source of infection was identified in 64% of patients in group 1 and in 44% in group 2 (P = 0.004); bacteremia was detected in 26% of cases in group 1 and in 12% in group 2 (P = 0.02).

**Conclusion** Septic shock with endotoxemia was associated with biochemical and clinical consequences including a higher PCT level, higher frequency of bacteremia, kidney failure, and death.

**P58 Procalcitonin as prognostic marker in severe sepsis of abdominal origin**

A Gonzalez-Lisorge1, C Garcia-Palenciano1, G Ercole1, T Sansano-Sanchez1, M Campos Aranda1, F Acosta Villegas1

1Hospital Universitario Virgen de la Arrixaca, Murcia, Spain; 2Universidad de Murcia, Murcia, Spain

**Introduction** We evaluated the utility of procalcitonin (PCT) as a marker of outcome in severe sepsis of abdominal origin (SSAO). SSAO is one of the most prevalent pathologies in surgical ICUs (sICUs). Mortality from 19 to 70% has been reported. Biomarkers are basic tools for diagnosis, follow-up and outcome of sepsis. One of the most studied in last decades has been PCT. Its levels and kinetics could be useful to evaluate the outcome of septic patients.

**Methods** We studied all patients admitted to a sICU with SSAO, from 2007 to 2008. Data collected were: PCT levels on days 1, 3 and 7, organ failure and mortality of patients with sepsis, and 40 (59.7%) patients of the other group had sepsis. PCT level, organ function and mortality of patients with sepsis was 41%. The mortality rate was higher in group 1, compared with group 2, and Kaplan–Meier survival analysis-plot (log-rank test) analysis showed statistical significance between the two groups (P = 0.001, log-rank test). A Gram-negative pathogen as the primary source of infection was identified in 64% of patients in group 1 and in 44% in group 2 (P = 0.004); bacteremia was detected in 26% of cases in group 1 and in 12% in group 2 (P = 0.02).

**Conclusion** Septic shock with endotoxemia was associated with biochemical and clinical consequences including a higher PCT level, higher frequency of bacteremia, kidney failure, and death.

**P59 Procalcitonin or lactate clearance, or both, for risk assessment in patients with sepsis? Results from a prospective US ICU patient cohort**

N Braun1, P Schuetz1, R Barutti1, D Amini1

1Kantonsspital Aarau, Switzerland; 2Morton Plant Hospital, Clearwater, FL, USA

**Introduction** Blood lactate level is a routinely used biomarker for management of patients in septic conditions in the ICU. There is a lack of clinical research data comparing lactate with novel sepsis biomarkers, such as procalcitonin, in regard to the diagnostic and prognostic potential. Herein, we investigated the diagnostic and prognostic value of initial lactate and procalcitonin levels and their kinetics within the ICU stay for prediction of positive blood cultures and fatal outcome in a known marker of sepsis and predictors in ICU settings.

**Methods** This is a retrospective, observational cohort study of adult patients with confirmed severe sepsis or septic shock and with at least one procalcitonin and lactate measurement on admission to the ICU of Morton Plant Hospital (Clearwater, FL, USA). Logistic regression models were calculated to assess the association of biomarkers with blood culture positivity and fatal ICU outcome with area under the curve (AUC) as a measure of discrimination.

**Results** The in-hospital mortality rate of the 1,075 included patients (age 68 years) was 23.8% (95% CI = 21.2 to 26.3%) and 18.4% of patients had positive cultures. In regard to the diagnostic value for bacteremic disease, initial procalcitonin had a higher discriminatory value (AUC 0.71) compared with initial lactate levels (AUC 0.52). In regard to prognosis, initial lactate level was the better mortality predictor (AUC 0.69) compared with procalcitonin (AUC 0.55), although both initial levels were significantly lower compared with APACHE III (P >0.05 for both comparisons). When looking at biomarker kinetics, procalcitonin decrease was more strongly associated with fatal outcome compared with initial levels alone (AUC 0.66), but still lower compared with lactate kinetics (AUC 0.73).

**Conclusion** Both biomarkers, procalcitonin and lactate provide diagnostic and prognostic information in ICU patients with sepsis, particularly when looking at biomarker kinetics. An evidence-based protocol incorporating both markers may further improve management of septic patients.
patients with sepsis ($P = 0.400, P = 0.169$). The area under the receiver operating characteristic curve (AUC) for diagnosis of sepsis according to PCT and IL-6 was 0.823, and 0.772 for the other patients group. The diagnostic sensitivity, specificity, positive predictive value, and negative predictive value of PCT for sepsis in other patients group were 79.5%, 81.5%, 86.1%, and 73.3% respectively, with a PCT cutoff value of 0.18 ng/ml. The diagnostic sensitivity, specificity, positive predictive value, and negative predictive value of IL-6 for sepsis in other patients group were 67.5%, 81.5%, 84.4%, and 62.9% respectively, with a IL-6 cutoff value of 74.43 pg/ml.

**Conclusion** PCT and IL-6 is useful predictive markers for diagnosing sepsis in adult patients (<65 years of age) with SIRS in the ED. But these markers are not useful for identification of sepsis in older patients.

**P61**

Procalcitonin levels in patients undergoing left ventricular assist device implantation

M Holek, J Kettner, J Franeková, A Jabor

Institute for Clinical and Experimental Medicine, Prague, Czech Republic

**Introduction** Procalcitonin (PCT) is used for diagnosis of a bacterial infection. Several works described nonspecific elevation of PCT after cardiac surgery with cardiopulmonary bypass (CPB) caused by systemic inflammatory response syndrome (SIRS) with various cutoff values for the presence of the infection (0.47 to 2.47 µg/l). However, in patients undergoing left ventricular assist device (LVAD), implantation data about PCT dynamics are lacking.

**Methods** PCT levels in 25 patients indicated for LVAD were prospectively assessed before surgery and during the postoperative period (days 1, 2, 14 and 30). Values were compared according to the presence of infectious complications (IC) and non-infectious complications such as acute renal failure (ARF) defined as injury by RIFLE criteria or necessity of right ventricular assist device (RVAD). Data were also analyzed utilizing combined endpoints A (ARF, RVAD) and B (IC, ARF, RVAD). Values are presented as median with interquartile range (in µg/l).

**Results** PCT levels were low before surgery (0.16, 0.10 to 0.35), increased significantly within the first (5.72, 2.18 to 9.75; $P < 0.001$) and second (5.94, 2.54 to 11.99; $P < 0.001$) day after operation and decreased on the 14th (0.27, 0.11 to 0.74) and 30th (0.10, 0.06 to 0.19) day. There was no significant difference in PCT values between patients with or without IC as well as with or without RVAD. ARF increased PCT level significantly only 14 days after LVAD implantation (0.68, 0.37 to 1.65 vs. 0.15, 0.34 to 0.34; $P = 0.001$). Subjects with endpoint A had significantly higher PCT values on the second (19.53, 5.66 to 63.12 vs. 3.95, 2.33 to 8.85; $P = 0.033$), 14th (0.55, 0.31 to 1.44 vs. 0.15, 0.0 to 0.34; $P = 0.020$) and 30th (0.19, 0.11 to 0.29 vs. 0.06, 0.05 to 0.13; $P = 0.016$) day after operation. Patients with endpoint B had significantly elevated PCT levels 2 (11.99, 3.23 to 24.16 vs. 3.95, 2.54 to 7.39; $P = 0.027$) and 14 (0.55, 0.28 to 0.90 vs. 0.13, 0.09 to 0.23; $P = 0.005$) days after surgery.

**Conclusion** PCT levels in patients undergoing LVAD implantation rise significantly in the first 2 days after surgery. Interestingly, this elevation is much higher than after routine cardiac surgery with CPB. Recent works suggest that PCT concentrations are affected by SIRS caused by contact with a nonphysiological surface. In the case of LVAD this immunological stimulation is long lasting and even more potent with additional RVAD or ARF treated with renal replacement therapy. In accordance with this hypothesis, our data show that the ability of PCT to detect infectious complication in LVAD patients is limited and its concentrations more probably correlate with postoperative complications in general.

Changes in procalcitonin and presepsin before and after immunoglobulin administration in septic patients

T Ikeeda, S Ogino, T Ueno, H Tanaka, S Suda

Hachioji Medical Center, Tokyo Medical University, Tokyo, Japan

**Introduction** The potentially envisaged actions of intravenous immunoglobulin (IVIg) on severe infectious disease include: virus or toxin neutralizing action; opsonic effect; complement bactericidal activity; and enhancement of sensitivity to antibiotics. In the case of severe infectious disease, antibiotics are often supplemented with administration of IVIg.

**Methods** The changes in sepsis markers (procalcitonin, presepsin, interleukin-6, C-reactive protein) followed by IVIg administration were investigated in severe sepsis or septic shock patients. The subjects were 410 patients admitted to an ICU with a diagnosis of severe sepsis or septic shock and from whom informed consent had been obtained for the present study. IVIg was administered intravenously for 3 days (5.0 g/day) and measurements were undertaken before administration (day 1), on the day after completion of administration (day 4), and on day 7. The items measured were procalcitonin, presepsin, IL-6, and CRP. The effect of IVIg administration on these markers was then studied. The IVIg studied was polyethylene glycol-treated human immunoglobulin injection fluid (2.5 g, 50 ml, one vial).

**Results** The patient APACHE II score were $24.9 \pm 8.2$, the SOFA score $9.1 \pm 3.7$, and the survival rate after 28 days 83.4%. The values before IVIg administration were: procalcitonin $36.0 \pm 463.3$ (median 110) ng/ml, presepsin $4,548 \pm 4,250$ (median 3,337) pg/ml, CRP $15.6 \pm 9.6$ (median 14.7) mg/dl, and IL-6 $13,860 \pm 47,299$ (median 630) pg/ml. All values were thus elevated. On the days after the completion of IVIg administration and on day 7, the level of almost all mediators (procalcitonin, presepsin, CRP, IL-6) decreased significantly. In patients with suspected severe sepsis and septic shock, presepsin reveals valuable diagnostic capacity to differentiate sepsis severity compared with procalcitonin, IL-6, CRP, and WBC. Additionally, presepsin and IL-6 reveal prognostic value with respect to 30 days and 6 months all-cause mortality throughout the first week of ICU treatment [1].

**Conclusion** The results of the present study found significant decreases of procalcitonin, presepsin and IL-6 resulting from 3 days of immunoglobulin administration, but evidence is still limited and this needs to be confirmed in larger studies.

Diagnostic and prognostic performance of PATHFAST Presepsin in patients with SIRS and early sepsis

E Spanuth1, R Carpio2, R Thomae3

1 DiAenneing Gmbh, Heidelberg, Germany; 2 Hospital Nacional Edgaro Rebagliati Martins-EsSalud, Lima, Peru; 3 Mitsubishi Chemical Europe, Dusseldorf, Germany

**Introduction** Presepsin (sCD14-ST) serves as a mediator of the response to infectious agents. First evidence suggested that presepsin may be utilized as a sepsis marker.

**Methods** Presepsin was determined at presentation (T0), after 8, 24 and 72 hours in 123 individuals admitted with signs of SIRS and/or infection. Primary endpoint was death within 30 days. Presepsin was determined using the POC assay PATHFAST Presepsin (Mitsubishi Chemical, Japan).

**Results** Mean presepsin concentrations of the patient group at presentation and of the control group were 1,945 and 130 pg/ml, respectively ($P < 0.0001$). Baseline presepsin differed highly significantly between patients with SIRS, sepsis, severe sepsis and septic shock.

Twenty-four patients died during 30 days. The 30-day mortality was 19.5% in total, ranging from 10 to 32% between the first and the fourth quartile of presepsin concentration. Nonsurvivors showed high presepsin values with increasing tendency during the course of the disease while in surviving patients this tendency was decreasing. See Table 1.

Conclusion Presepsin demonstrated a strong relationship with disease severity and outcome. Presepsin provided reliable discrimination between SIRS and sepsis as well as prognosis and early prediction of 30-day mortality already at admission. Presepsin showed close association with the course of the disease.

Table 1. Presepsin values with increasing tendency during the course of the disease while in surviving patients this tendency was decreasing. See Table 1.

Conclusion CD64 and PCT were a useful biomarker for detecting sepsis for ICU patients with AKI.

P65 Prognostic value of procalcitonin in respiratory tract infections across clinical settings

A Kutz, B Mueller, P Schuetz, for the IPD Study Group
Kantonsspital Aarau, Switzerland

Introduction Whether the inflammatory biomarker procalcitonin (PCT) provides prognostic information across clinical settings and different acute respiratory tract infections (ARI) is poorly understood. Herein, we investigated the prognostic value of admission PCT levels to predict adverse clinical outcome in a large ARI population.

Methods We analyzed data from 14 trials and 4,211 ARI patients to study associations of admission PCT levels and setting specific treatment failure and mortality alone at 30 days. We used multivariable hierarchical logistic regression and conducted sensitivity analyses stratified by clinical settings and ARI diagnoses to assess the results' consistency.

Results Overall, 864 patients (20.5%) experienced treatment failure and 252 (6.0%) died. The ability of PCT to differentiate patients with and without treatment failure was highest in the emergency department setting (treatment failure; area under the curve (AUC): 0.64 (95% confidence interval (CI): 0.61, 0.67), adjusted odds ratio (OR): 1.85 (95% CI: 1.61, 2.12), P < 0.001 – mortality; AUC: 0.67 (95% CI: 0.63, 0.71), adjusted OR: 1.82 (95% CI: 1.45, 2.29), P < 0.001). In lower respiratory tract infections, PCT was a good predictor of identifying patients at risk for mortality (AUC: 0.71 (95% CI: 0.68, 0.74), adjusted OR: 2.13 (95% CI: 1.82, 2.49), P < 0.001). In primary care and ICU patients no significant associations of initial PCT levels and outcome were found. See Figure 1.

Conclusion Admission PCT levels are associated with setting specific treatment failure and provide most prognostic information in ARI in the emergency department setting.

Figure 1 (abstract P65). Multivariate regression analysis for estimation of predictive value of PCT levels on admission stratified by adverse events and mortality in different settings and diagnoses. *Treatment failure, †mortality. ARI, acute respiratory tract infection; ECOPD, exacerbated chronic obstructive pulmonary disease; CAP, community-acquired pneumonia; VAP, ventilator-associated pneumonia; Adj., adjusted; OR, odds ratio; CI, confidence interval.
Introduction The objective of this study was to evaluate the neutrophil to lymphocyte count ratio (NLCR) versus procalcitonin (PCT) in diagnosing bacteremia in the emergency department (ED). The NLCR is a biomarker that appears early in the course of the acute inflammatory response and reaches maximum levels within 4 hours after onset. An elevated NLCR has been shown to correlate to bacteremia at a cutoff level of >10 [1]. It is rapidly analyzed on a full blood cell count at low cost. The lowest recommended cutoff level for PCT is <0.5 mg/ml.

Methods We randomly chose 425 patients from a 9-month epidemiologic study on the incidence of community-onset severe sepsis and septic shock in western Sweden 2011 to 2012. In total, 207 had severe sepsis and 218 had sepsis, mean age 71.2 versus 64.2 years; males 59%. APACHE II was measured on admission and BSI day. The NLCR was analyzed immediately, PCT later on plasma frozen at –80°C. A total of 122/425 patients had bacteremia, 72 (35%) in the sepsis group versus 50 (23%) in the sepsis group. Most common findings were Staphylococcus aureus (n = 33), Streptococcus aureus (n = 24), streptococcal spp. (n = 33) and other enterobacteriaceae spp. (n = 17).

Results The NLCR shows significantly higher sensitivity than PCT at recommended cutoff levels for bacteremia. Interestingly, this is true even for all 207 patients with severe sepsis, irrespective of bacteremia or not. Sensitivity figures with 95% confidence interval: bacteremia (n = 122): NLCR 80% (0.73 to 0.87) versus PCT 66% (0.58 to 0.75), P = 0.01; severe sepsis with bacteremia (n = 72): NLCR 85% (0.77 to 0.93) versus PCT 70% (0.59 to 0.81), P = 0.03; and severe sepsis but no bacteremia (n = 135): NLCR 71% (0.65 to 0.77) versus PCT 61% (0.54 to 0.68), P = 0.03.

Conclusion The NLCR can be used in the ED as a biomarker for bacteremia as well as severe sepsis and seems to perform as well as or even better than PCT in this setting. Rapid response, low cost and no need for extra sampling make it useful as a screening tool.

Introduction The purpose of the study was to assess the prognostic value of pro-adrenomedullin (pADM), C-reactive protein (CRP) and procalcitonin (PCT), lactate (LT), albumin (ALB), cholesterol (CHOL), white blood cell (WBC) and severity score in patients with severe sepsis or septic shock.

Methods A prospective, observational study in adult patients with severe sepsis or septic shock in a polyvalent ICU. Demographics, severity scores (APACHE II and SOFA) and all of the biomarkers were included. Illness severity was assessed by SOFA score on both admission and BSI day. Demographic, clinical, and laboratory data including PCT and CRP levels, as well as the white blood cell (WBC) count on the day of the BSI were recorded. PCT was measured by an electrochemiluminescence analyzer and CRP by the tholosimetric method (Roche, Switzerland).

Results A total of 64 ICU patients (mean age 58 ± 18 years, 39 males) with BSIs were included. SOFA score was 9 ± 4 on ICU admission and 8 ± 4 on the day of BSI. In 30 of these patients Candida spp. were isolated in blood culture (candidemia group) whereas the remaining 34 had a bacterial etiology of BSI (bacteremia group). Serum PCT concentrations remained within normal ranges in most patients with candidemia whereas a wide range was observed in patients with bacteremia. Mean values of PCT and CRP levels were higher in the bacterial than in the candidemia BSI group: 18.5 ± 32.2 versus 0.73 ± 1.40 ng/ml, P < 0.001 and 17.7 ± 10.3 versus 8.9 ± 8.0 mg/dl, P = 0.001, respectively. There was a significant difference in WBC count between the two groups: 19.46 ± 10.174 versus 11.000 ± 5.440, P < 0.001 for the bacteremia and candidemia BSI group, respectively. A ROC curve analysis of the predictive ability of PCT showed an AUC of 0.79 (P < 0.001). When a cutoff point of 0.40 ng/ml was selected using Youden's J statistic, a low value of PCT had in our sample a negative predictive value of 0.76 and a likelihood ratio (negative) of 0.30.

Conclusion A low serum PCT value could be considered as a diagnostic marker in distinguishing between BSIs of candidal or bacterial origin in ICU patients with varying severity of sepsis.

Low serum iron is a risk factor for ICU-acquired bacteremia: study of a large cohort database
S Fernandes1, D Bruno2, J Morgado3, C Calle4, C Ferreira4
1Centro Hospitalar Lisboa Norte CHLN, Lisbon, Portugal; 2Hospital Fernando Fonseca, Lisbon, Portugal; 3Centro Hospitalar de Lisboa Central, Lisbon, Portugal; 4Instituto Português de Oncologia, Lisbon, Portugal; 5National Institute of Legal Medicine and Forensic Sciences, Coimbra, Portugal

Introduction Bloodstream infections in the ICU are a major trigger of morbidity and mortality. Several risk factors for bacteremia have been previously identified, such as presence of a central venous catheter or invasive ventilation [1,2]. Iron is a key element for bacteria growth, and its metabolism is extensively altered by inflammation. We aim to determine whether iron deficiency is a risk or protective factor for bacteremia in the ICU.

Methods We performed a retrospective analysis of patients included in the MIMIC-II database, an ICU database that collected data from patients admitted to the medical, surgical, coronary and cardiac surgery ICU of Boston's Beth Israel Deaconess Medical Center during a period of 7 years. We performed logistic regression models to assess the association between iron and bloodstream infection.

Results We included 3,980 patients, 2,988 with low serum iron (<60 ng/ml) and 992 with normal/high serum iron (≥60 ng/ml). During their first stay in the ICU, 351 (8.82%) patients developed bloodstream infections. Low serum iron was associated with increased odds of bloodstream infection (OR: 1.37; 95% CI: 1.04 to 1.80). After adjusting for age, gender, Simplified Acute Physiology Score, presence of central venous catheter, ICU type, transfusions performed before iron measured, neoplastic disease, diabetes mellitus, hepatic disease, congestive heart failure and ferritin levels, low levels of iron were still associated with an increased odds of bacteremia (OR: 1.41; 95% CI: 1.03 to 1.9). In contrast, low serum iron was associated with a decreased risk of death in the hospital (adj OR: 0.73; CI: 0.57 to 0.95).

Conclusion Low serum iron increases the risk of bloodstream infection in the ICU, and should be considered as a risk factor to stratify patients’ risk of bacteremia during ICU stay.

References
Methods After ethics committee approval, patients admitted to the ICU, older than 18 years, who were thought to have a central venous catheter (CVC) for more than 48 hours, and whose first catheter was inserted in the ICU were included in the study. Staff were educated before the study and periodically during the study. Catheter care and insertion were applied according to the guidelines. The study was planned as three sequences. In the first group, catheter care was made with a sterile gauze pad. In the second and third groups, catheter care was made with chlorhexidine gluconate impregnated dressing. Also in the third group, a silver-coated needleless connector was inserted into the tip of venous catheters.

Results Totally 105 patients were included in the study and every group included 35 patients. There was no difference between groups when evaluating reasons for catheter insertion. There was no statistically significant difference according to emergent or elective catheterization, trying times, or catheter insertion side (P > 0.05). CRBSI was determined in two patients in group 1, in one patient in group 2, and in no patient in group 3. In group 1 it was observed on the 4th and 11th days. In group 2 it was observed on the 18th day after catheterization. Before the study, a statistically significant decrease was determined in CRBSI in two patients in group 1, in one patient in group 2, and in no patient (was assigned in CRBSI ratios in Groups 2 and 3 (4.84/1,000, 2.22/1,000, Municipal Hospital, Osaka, Japan; 7Sendai City Hospital, Miyagi, Japan; 8Kobe City Medical Center General Hospital, Hyogo, Japan; 9National Hospital Organization Kyotanabe Medical Center, Kyoto, Japan; 10Kyuusyu University Hospital, Fukuoka, Japan; 11Nippon Medical School Chiba Hokusoh Hospital, Tiba, Japan Critical Care 2015, 19(Suppl 1):P73 (doi: 10.1186/cc14153)

Introduction The current CDC guidelines for the prevention of intravascular catheter-related infections skin preparation with a greater than 0.5% chlorhexidine with alcohol solution before central venous catheter (CVC) or peripheral arterial catheter (AC) placement. However, few studies investigated the superiority of 1% alcoholic chlorhexidine gluconate (1% CHG) over either 0.5% alcoholic chlorhexidine gluconate (0.5% CHG) or 10% aqueous povidone iodine (10% PVI) for the prevention of catheter colonization. The aim of this study is to compare the effectiveness of three skin antiseptic solutions for the prevention of intravascular catheter colonization.

Methods This multicenter prospective randomized controlled trial was conducted in 15 Japanese ICUs from December 2012 to March 2014. Patients over 18 years of age undergoing CVC and AC placement in the ICU are randomized to have one of three skin antiseptic preparations before catheter insertion. After removal of the catheter, the distal tip is cultured using semiquantitative or quantitative techniques. The incidence of catheter colonization and catheter-related bloodstream infection (CRBSI) is compared between the three groups.

Results A total of 997 catheters were placed, including 339 catheters using 1% CHG, 329 using 0.5% CHG, and 329 using 10% PVI. The median duration of catheter indwelling in the entire population was 3.7 days with an interquartile range of 2.0 to 6.7 days, with no significant difference between the groups (P = 0.36). Thirteen catheters (5.1%) in the 10% PVI group were positive for catheter-tip colonization, whereas six catheters (2.2%) in the 1% CHG group and five catheters (1.9%) in the 0.5% CHG group were positive (P = 0.07). The probability of catheter colonization was significantly higher in the 10% PVI group than each CHG groups (P = 0.028, log-rank test). The incidence of catheter colonization and CRBSI is compared between the three groups.

Conclusion In this randomized controlled trial comparing the effectiveness of three cutaneous antiseptic solutions for the prevention of catheter colonization, either 0.5% or 1.0% CHG was superior to 10% PVI.

P74 Catheter-associated bloodstream infections in an ICU of a university hospital in Wroclaw, Poland: an international nosocomial infection control consortium’s findings

W Duszyńska1, VD Rosenthal1, A Litwin1, E Woznica1, A Kubler1
1University Hospital, Wroclaw, Poland; 2International Nosocomial Infection Control Consortium, Buenos Aires, Argentina Critical Care 2015, 19(Suppl 1):P74 (doi: 10.1186/cc14154)

Introduction Catheter-associated bloodstream infections are serious but potentially possible to reduce complication of treatment in the ICU. The aim of the study was to evaluate the frequency and etiology of central line-associated bloodstream infections (CLA-BSI) in ICU patients according to the International Nosocomial Infection Control Consortium (INICC) project.

Methods A prospective, observational study was conducted in the 20-bed ICU of the University Hospital in Wroclaw from January 2011 to November 2014. CLA-BSI were diagnosed and evaluated according to protocols standardized by the INICC. The density of CLA-BSI/1,000 central line-days, the incidence index/100 admissions to the hospital, the central line utilization ratio (CL-UR) as well as the microbiological profile of CLA-BSI were evaluated. The results were compared with our earlier published data and with the findings of international reports.

Results Among 1,746 ICU patients, CLA-BSI were diagnosed in 69 cases. The incidence index was 3.88/100 admissions to the ICU. CLA-BSI were diagnosed in 18% of the overall number (381) of device-associated healthcare-associated infections. Central line was used in 91.4 ± 4.4% of patients during 19,819 patient-days and 18,155 central line-days. The median density of CLA-BSI/1,000 central line-days was 3.88/3.77/3.36 and 0.0 accordingly in years 2011/2012/2013 and 2014 (from January to November). The main pathogens of CLA-BSI were CN Staphylococci (22%), Staphylococcus aureus (21%), and Enterobacteriaceae (29%). In this study, the density of CLA-BSI was about 50% lower (2.75 (2.0 to 6.06)) than in our previous study and in the INICC’s report (2014), but higher than in the CDC’s NHSN (2012) report.

Conclusion The implementation of the infection control program and preventive interventions for patients with central venous catheters improved the safety and quality of healthcare in the ICU by reducing CLA-BSI rate.

Reference
not easy to avoid. It is important to know what happens to neutropenic patients admitted to the ICU because of sepsis from any source, in whom catheter infection cannot be excluded.

Methods A retrospective, cohort, descriptive study was carried out between January 2013 and November 2014. Epidemiology data were collected from all neutropenic patients admitted to the ICU who came from hemato-oncology services and had an implanted central venous catheter. Microbiology results and data related to the catheter removal were described.

Results A total of 15 patients were included, mean age was 53 years old and 66% were male. The implanted catheter was removed in 80% of patients. Platelet transfusion was needed in 100% of patients before catheter removal and no complication was observed during catheter removal or in the insertion of a new one. In 53% of patients, catheter infection was confirmed a posteriori.

Conclusion Removal of an implanted central venous catheter from neutropenic patients admitted to the ICU due to sepsis from any source can be beneficial for this kind of patient as it was found that in more than 50% of patients catheter infection was confirmed a posteriori.

P76

Effect of insertion route on risk of central line-associated bloodstream infection in critically ill patients

R Alhubail, N Hassan

KFSSH-D, Dammam, Saudi Arabia

Introduction Femoral, jugular or subclavian central venous catheterization (CVC) is routinely performed during the care of the critically ill. These invasive procedures contribute to additional morbidity, mortality, and costs derived from the interactions between traumatic, infectious and other complications. The aim of this study is to determine whether the subclavian, jugular or femoral central venous access (CVA) routes have an effect on the incidence of CLABSI in critically ill patients and to compare between these routes regarding major complications and ICU mortality.

Methods A retrospective observational study in a medical and surgical ICU in a tertiary care hospital on adult patients admitted from January 2010 to December 2013. The study enrolled 845 patients divided into 283 internal jugular CVC (IJ), 270 subclavian CVC (SCC) and 287 femoral CVC (FC) in which the catheters were inserted in the ICU by experienced physicians with at least 50 previously successful trials of central line insertion, using CVC bundle checklist. ICU length of stay, incidence of complications, APACHE II score adjusted severity and mortality were calculated for each group.

Results Patient and catheter characteristics including the duration of catheterization were similar in all groups. The rate of CLABSI in the IJC, SCC and FC groups was 5.8 versus 7.2 versus 4.45 per 1,000 catheter-days respectively with \( P = 0.35 \). ICU mortality was 134 (47%) cases of the ICU group, 108 (39%) cases of the SCC group and 113 (39%) cases of the FC group. There was no significant difference between the three groups of CVC in the incidence of CLABSI rate in the critically ill patients, and a slight increase in ICU mortality in the IJC group compared with the other two groups. Pneumothorax occurred in six (2.2%) cases of SCC and 11 (3.8%) cases of IJC with no significant difference between the two groups as the P value was 0.3.

Conclusion Site of insertion of CVC does not appear to affect the rate of CLABSI among critically ill patients. Pneumothorax was recorded in SCC and IJC groups with no statistical preference to either group.

P77

Role of neutrophil extracellular traps against soft tissue infections

N Yamamoto1, M Ojima2, S Hamaguchi1, T Hirose2, R Takegawa2

Division of Infection Control and Prevention, Osaka University Graduate School of Medicine, Suita, Japan; 2Osaka University Graduate School of Biomedical Sciences, Nagasaki, Japan

Introduction Neutrophils work as the frontline of defense against infections and neutrophil extracellular traps (NETs) are one of the immune systems to suppress dissemination of infection by the netted chromatin decorated with antibacterial molecules. It was reported that NETs play an important role in various kinds of infections such as pneumonia. However, there is no report on NETs in patients of soft tissue infections. In this study, we evaluated NET production in pus and clarified the role of NETs as a host defense in patients of soft tissue infections.

Methods This study was conducted in the ICU of the Trauma and Acute Critical Care Center at Osaka University Hospital. We collected pus from the patients of soft tissue infections at the time when drainage or debridement was performed and when clinical improvement was observed. The smears of pus specimens were examined by immunohistochemistry to visualize the major NET components: DNA, neutrophil elastase, and histone H1. Concurrently, the patients' clinical data and laboratory data of blood were recorded to analyze the relationship with NET production.

Results A total of five patients were included in this study and drainage of abscess or debridement of infection site was performed in all of the cases. Four patients of them were diagnosed as necrotizing soft tissue infections by Clostridium spp. (n = 1) and Bacteroides spp. (n = 3) and the other was diagnosed as cervical abscess by Streptococcus spp. In all cases, no NETs but neutrophils were identified in the first pus; however, NETs appeared in the later smears as the patients' condition was getting better.

Conclusion These results suggested that NETs also worked as an immune system against soft tissue infections. Drainage or debridement of infection focus might promote NET production.

Use of nanotechnology-based surface antiseptic solutions in the ICU

Y Kuplay, N Akgun, C Agalar, H Aydýn, O Alýcý, G Turan

FSM Teaching and Research Hospital, Istanbul, Turkey

Introduction In our study, we aimed to compare the application of benzalkonium chloride (BC) – a nanotechnology-based product – for 24-hour periods and didecyl dimethyl ammonium chloride (DDAC) for 12-hour periods regarding efficiency in application of surface antiseptics in the ICU.

Methods Two different areas with eight beds at both sides of a common corridor in the ICU were named as areas A and B. BC was applied in area A with 24-hour periods and DDCA was applied in area B with 12-hour periods for surface cleaning. Samples were taken from a total of 20 different surfaces including nurse-station desks, phones, keyboards, beds, bedside monitors and ventilators by the same infection control nurse every 24 hours from area A and every 12 hours from area B for 7 days. Swab samples were cultured on 5% sheep bloody agar and McConkey agar in the laboratory. Then the cultured mediums were incubated at 35 to 37°C in an aerobic environment for 18 to 24 hours. NCSS (Number Cruncher Statistical System) 2007 and PASS 2008 Statistical Software (UT, USA) programs were used for the statistical analysis.

Results There were no statistical differences between two groups (Table 1).

Conclusion The effect of a good surface disinfectant should begin immediately and it should have a long-lasting disinfecting effect on the surface. DDAC is an efficient disinfectant used in medicine and the food industry to protect the surfaces. However, it may cause severe skin itching. BC, which is a nanotechnology-based product, leaves its active metabolites on the surface; it is applied by constituting a spongy layer. Since the efficiency of BC lasts for 24 hours and it is applied to perform cleaning with 24-hour intervals, we think that it is preferable with regards to workforce gain and cost.

P79
Reduction of deep surgical site infections in cardiac surgery by introducing a multimodal infection control program
A Rutten, JP Ory, L Jamaer, A Van Assche, J Dubois
Jessa Ziekenhuis, Hasselt, Belgium

Introduction Deep surgical site infections (DSSI) are a major complication after cardiac surgery with a high mortality rate and reported incidences between 0.5 and 5%. Implementing a comprehensive infection control program (ICP) reduces this incidence [1]. The incidence in our hospital varied from 3.1 to 3.8%, which was considered too high. We evaluated the impact of introducing a multimodal ICP on the incidence of DSSI.

Methods We noticed a too high incidence of DSSI after cardiac surgery during an observational 3-year period (Figure 1). In February 2013 we introduced a bundle of interdisciplinary infection control measures. Medical and nursing staff of all involved departments took part in developing and implementing these guidelines. Besides emphasizing the importance of existing guidelines (antiseptic shower, hair removal by clipper, strict hand hygiene, prophylactic antibiotics, limiting OR traffic, tight glycemic control (80 to 110 mg/dl), and so on), new strategies were introduced. The most important new strategies were nasal decolonization with mupirocin twice daily 48 hours perioperatively, preoperative antiseptic skin preparation twice (chlorhexidine gluconate 0.5%), applying topical skin adhesive to the sternal wound postoperatively and in the case of CABG procedures maintaining a strict barrier between the vein harvesting procedure and the chest procedure.

Results We observed a significant reduction in DSSI rates in cardiac surgery following implementation of a multimodal ICP from 3.1% in 2010 down to 0.23% in November 2014 (Figure 1).

Figure 1 (abstract P79). Incidence of DSSI.

Conclusion Implementing a multimodal ICP significantly reduced the incidence of DSSI in our hospital but it remains difficult to identify which interventions were most effective.

Effect of chlorhexidine and urinary catheter infection prevention in a Brazilian coronary ICU
GM Plantier1, CE Bosso1, BN Azevedo1, AC Correa1, AL Silva1, V Raso1
1Instituto do Coração de Presidente Prudente, Brazil; 2Faculdade de Medicina – UNOESTE, Presidente Prudente, Brazil; 3Santa Casa de Presidente Prudente, Brazil

Introduction Urinary catheter insertion is a common procedure in ICUs and can be an important cause of infection in the hospital environment [1,2]. We aimed to analyze the effect of chlorhexidine on long-term urinary catheter insertion and urinary tract infection (UTI) during a 5-year period in patients admitted to a coronary ICU.

Methods Analysis of patients admitted to a coronary ICU of a medium-sized hospital in Brazil from January 2010 to May 2014. The institutional protocol of periprocedural antisepsis was changed from iodine-based antiseptic to chlorhexidine in 2012. The UTI diagnosis was based on urine culture (>10^4 colony-forming units per ml of urine) associated with at least one clinical/laboratory abnormality (fever >38°C, urinaria urgency, increased urinary frequency, dysuria, or suprapubic or lumbar pain). The UTI rate represents the urinary tract infections associated with long-term urinary catheter (patient with UTI associated with long-term urinary catheter divided by patients with long-term urinary catheter x 1,000).

Results The urinary tract infection rates were 4.8 (year 2010: patients-day^-1 (n: 2,511), long-term urinary catheter-day^-1 (n: 1,455), device usage rate (958%)), 4.4 (year 2011: patients-day^-1 (n: 2,529), long-term urinary catheter-day^-1 (n: 1,140), device usage rate (45%)), 0.0 (year 2012: patients-day^-1 (n: 2,660), long-term urinary catheter-day^-1 (n: 783), device usage rate (29%)), 0.0 (year 2013: patients-day^-1 (n: 2,573), long-term urinary catheter-day^-1 (n: 960), device usage rate (37%)), and 0.0 (year 2014: patients-day^-1 (n: 1,070), long-term urinary catheter-day^-1 (n: 444), device usage rate (42%)).

Conclusion The use of chlorhexidine in the periprocedural antisepsis of urinary catheterization contributed to the decrease of urinary tract infections associated with long-term urinary catheter in patients admitted to the coronary ICU.

Effect of daily bathing with chlorhexidine on hospital-acquired bloodstream infection in critically ill patients: a meta-analysis of randomized controlled trials
E Choi1, J Park1
1Yeungnam University College of Medicine, Daegu, South Korea; 2Uijeongbu St. Mary’s Hospital, Uijeongbu, South Korea

Introduction Whole-body skin decolonization with chlorhexidine in critically ill patients reduces multidrug-resistant bacterial colonization, and catheter-related bloodstream infection (BSI). We performed a meta-analysis of randomized controlled trials to determine whether daily bathing with chlorhexidine decreased hospital-acquired BSIs in critically ill patients.

Methods We searched the MEDLINE, EMBASE, and Cochrane Central Register of Controlled Trials databases to identify randomized controlled trials that compared daily bathing with chlorhexidine and a control (daily bathing with soap and water or nonantimicrobial washcloths, or implementing serial MRSA screening and isolation) in critically ill patients. The primary outcome was hospital-acquired BSIs. Secondary outcomes were adverse effects of chlorhexidine and the incidence of identified pathogens.

Results This meta-analysis included four studies. The overall incidence of hospital-acquired BSIs was significantly lower in the chlorhexidine group compared with the control 0.80 (95% CI, 0.71 to 0.90; P < 0.001; I^2 = 29.4%). Gram-positive (RR = 0.59, 95% CI, 0.44 to 0.79, P = 0.000; P = 46.0%) and MRSA-induced (pooled RR = 0.64; 95% CI, 0.47 to 0.88, P = 0.006; P = 0.0%) bacteremias were significantly less common in the chlorhexidine group. Chlorhexidine did not affect Gram-negative bacteremia or fungemia. The overall incidence of adverse events, such as skin rashes, was similar in both groups.
Conclusion Daily bathing with chlorhexidine was associated with a reduction in the rates of hospital-acquired BSIs without significant complications in critically ill patients. It also decreased the incidence of Gram-positive hospital-acquired BSIs, especially MRSA.

Introduction Hand hygiene is the single most effective but least practiced action in breaking the chain of transmission of microbes. Studies have shown a correlation between the compliance of hand hygiene and its impact on the health outcome.

Methods A quasi-experimental study was done in three level III ICUs of a tertiary care hospital in Kolkata (January to April 2014). Data were collected on existing hand hygiene compliance rate, ventilator-associated pneumonia (VAP) rate, catheter-related bloodstream infection (CRBSI) rate, catheter-related urinary tract infection (CAUTI) rate, and average ICU length of stay in the abovementioned units. Root cause analysis was done and interventions were developed to improve hand hygiene compliance and was implemented (July to October 2014). Comparison was done between preintervention and postintervention periods.

Results In the preintervention period (January to April 2014) the hand hygiene compliance among the caregivers was found to be 40%, VAP rate (8.27), CRBSI rate (3.42), CAUTI rate (5.27), SMR (1.14) and average ICU length of stay was 6 days ± 5.85 SD (median 4.5). Interventions were developed and implemented as follows: education and awareness—road shows; positive reinforcement; secret watch nurse; e-ICU—electronic surveillance; ring the bell once every hour—baseline hand hygiene; visual reminders; availability of alcohol-based hand rub, soap and water and sinks; random hand swabs; and compliance audits. In the postintervention period (July to October 2014) data showed a significant improvement in the hand hygiene compliance (75%). Further analysis showed an association with decrease in the incidence of VAP rate (4.71), CAUTI rate (3.51), CRBSI rate (2.65), SMR (1.05) and average ICU LOS 5.05 days ± 4.03 SD (median 4).

Conclusion Improved hand hygiene compliance can be attributed to decreased incidence of VAP, CRBSI, CAUTI, SMR and average ICU LOS. This does definitely impact the overall clinical outcome. However, continued surveillance of hand hygiene compliance and regular audits is of utmost importance to make the change sustainable.

Introduction Multidrug-resistant organism (MDRO) infections in critically ill patients are often life-threatening. To prevent nosocomial infections of MDRO, we made an infection control bundle in our ICU in 2013. In this study we evaluated the effect of our infection control bundle to prevent nosocomial MDRO transmission and infection.

Methods Our infection control bundle consists of preemptive contact precaution to all care, active surveillance culture and isolation of patients with MDRO. This bundle was applied to all patients admitted to our ICU since 2013. The study period to evaluate the effects of the bundle was from April 2012 to March 2014, and we divided it into two periods; first period (before introduction of the bundle) and second period (after introduction of the bundle). We compared the incidence of nosocomial transmission and infection of MDRO between the two periods. MDRO was defined as bacteria that were resistant to more than three kinds of antibiotics. Nosocomial transmission was defined when MDRO was detected later than 48 hours after admission. Nosocomial infection was diagnosed according to the National Nosocomial Infection Surveillance Manual.

Results Admission to the ICU comprised 363 patients in the first period and 380 patients in the second period. The incidence of transmission was decreased from 48 (13.2%) to 21 (5.5%) in methicillin-resistant Staphylococcus aureus (MRSA), from 16 (4.4%) to 8 (2.1%) in multidrug-resistant Acinetobacter baumannii. The incidence of nosocomial infection by MDRO was also decreased from 23 (6.3%) to 17 (4.5%) in pneumonia, from five (1.4%) to two (0.3%) in urinary tract infection, and from 12 (3.3%) to one (0.3%) in surgical site infection. The incidence of antibiotic use for MDRO infection was decreased from 41 (11.3%) to 24 (6.3%) in anti-MRSA antibiotics, and from 19 (5.2%) to eight (2.1%) in carbapenems.

Conclusion Introduction of infection control bundle in the ICU reduced the incidence of nosocomial MDRO transmission and infection, which resulted in the reduction of anti-MRSA antibiotics and carbapenems use in critically ill patients.

Introduction Good hand hygiene (HH) is critical to infection control in the ICU. Electronic HH surveillance systems are purported to improve HH practices. Such a system was recently trialed in our ICU. The system is based on radiofrequency transponders in three locations; bracelets worn by ICU personnel; on all HH product dispensers; and above each patient’s bed. By correlating input from these three sources the system detects whether HH was performed before and after each patient contact. In the event that HH is not performed, the bracelet alerts the user (by vibration) in real time. This study represents a clinical validation of the system.

Methods ICU staff (nurses and physicians) were followed by a trained observer over 60-minute periods. Each movement and contact during the period was documented. HH opportunities were determined according to WHO criteria and actual HH performance recorded. Observer and electronic data were compared for number of opportunities, HH performance and compliance. A satisfaction questionnaire was distributed to all users. Pair student’s t test was used for comparison of the observer and electronic data.

Results Observations were made over 56 time periods that included 836 HH opportunities and 485 occasions when HH was performed. The observer recorded 10.9 ± 7.6 HH opportunities/hour compared with 6.8 ± 6.9 for the electronic system (p < 0.001). HH performance occurred on 8.7 ± 3.9 occasions/hour versus 6.0 ± 3.1 occasions/hour as recorded by the electronic system (p < 0.001). Overall HH compliance was 62.5 ± 17.7% versus 72 ± 21.0% respectively (p = 0.523). On comparison of specific observation periods, there was poor correlation between compliance as recorded by the observer and electronic system (r = 0.03, P = 0.915). Satisfaction questionnaires were completed by 41 personnel. Satisfaction with the system was low or very low for 21/41 (61%). System inaccuracy (either bracelet alerts without cause, or lack of bracelet alerts when HH was required) was the most common reason for dissatisfaction (3/41, 76%), followed by physical discomfort from the bracelet (18/41, 44%).

Conclusion The electronic HH system consistently underestimated both HH opportunities and HH performance. The main reason for dissatisfaction with the system was inaccuracy of bracelet alerts. These data suggest that for an electronic system to be accepted by ICU staff, it has to be highly accurate and comfortable for the user.

Introduction The use of intravascular catheter devices is often associated with serious bloodstream infections due to microbial contaminations. To minimize risk of such infections NIOSH recommends...
the use of closed system transfer devices (CSTDS). To evaluate the microbial tightness of CSTDS we developed two methods which simulate the bioburden in ambient air of operating rooms and ICUs. Methods: The methods simulate airborne and touch contamination. We tested the microbial tightness of the integrated Safeflow® valve of a Mini-Spike® which is used for drug admixture. The airborne contamination was done in an exposure chamber in which a nebulizer distributed defined B. subtilis spore aerosols [1]. A Mini-Spike® was inserted into a vial of 0.9% sodium chloride solution (NaCl). A nebulizer with a suspension of 4.8 x 10^5 CFU spores of B. subtilis per ml was used to generate an aerosol for 1 minute. The volume of B. subtilis suspended nebulized per minute was 0.278 ml. This corresponds to 1.34 x 10^4 aerosolized spores in the exposure chamber, which has a volume of 0.24 m³ (5.6 x 10^10 CFU per m³ air). The used concentration was 100 times higher than the microbial burden found in hospitals [2]. After nebulization the valve was disinfected and NaCl was withdrawn into a syringe at certain time intervals. The NaCl was incubated on tryptic soy agar at 37°C for 48 hours. Results were documented as CFU. For touch contamination, a Mini-Spike® was attached to a vial of NaCl. The valve of the Mini-Spike® was contaminated with 10^7 CFU Staphylococcus aureus. The subsequent procedure was done as described above. Results: Out of nine tested valves, none showed transmission of B. subtilis spores after airborne contamination. Three out of nine tested valves were contaminated with S. aureus after touch contamination. Conclusion: Our study shows that both methods are suitable for evaluating the microbial tightness of CSTDS.

A survey of UK acute clinicians’ knowledge of personal protective requirements for infectious diseases and chemical, biological, and radiological warfare agents
AR Bond¹, A Buckingha², J Schumacher³
¹Guy’s and St Thomas’ NHS Trust, London, UK; ²St George’s Healthcare NHS Trust, London, UK.

Introduction: We conducted a survey to assess clinicians’ knowledge of personal protective equipment (PPE) requirements for infectious diseases and biochemical warfare agents. A safe level of PPE is essential when treating patients with highly infectious diseases or those contaminated with hazardous substances. The recent Ebola virus disease (EVD) outbreak in West Africa has highlighted that, although uncommon, contagious diseases with high mortality rates can be a threat to healthcare systems at local, national, and international levels [1]. Chemical, biological, radiological or nuclear (CBRN) contamination presents similar risks.

Methods: A validated, hand-delivered, multiple-choice questionnaire [2] was used to assess intensive care, emergency medicine, and anesthetics specialist registrars’ knowledge of respiratory and skin protection needed during a resuscitation scenario with advanced life support. Participants selected the PPE required for the biological hazards: EVD, severe acute respiratory syndrome (SARS), inhalational anthrax, plague and smallpox; and the biochemical hazards: sarin, hydrogen cyanide, phosgene and mustard gas (dichlorodiethyl sulphide). Responses were compared with UK national recommendations and a previous survey in 2009 [2].

Results: Ninety-eight clinicians (anesthetics n = 21, emergency medicine n = 21, intensive care medicine n = 26) completed surveys. The best knowledge (76% correct) was for SARS, with less knowledge for anthrax, plague, EVD, and smallpox (60%). We found limited knowledge for chemical warfare agents (20 to 30%). Sixty to 80% of all incorrect responses were over-rated. There was no difference in knowledge compared with previous published results [2].

Conclusion: Despite national and regional training since previous surveys [2], the results indicate that further training on PPE is required for clinicians treating patients exposed to infectious diseases and CBRN agents, ideally in a simulation setting. Further research into whether the required levels of PPE are readily available to clinicians would be pertinent.

Methods We present a descriptive study in an ICU between the years 2001 and 2013 on the incidence of patients with cutaneous mucormycosis. Sociodemographics, comorbidities and laboratory data were recorded. Clinical data were collected to calculate the APACHE score. The main outcome was to analyze the epidemiological characteristics of patients with cutaneous mucormycosis and mortality.

Results Seven patients were identified with cutaneous mucormycosis between the years 2001 and 2013. The mean age of patients was 52 ± 4, with an APACHE score of 19 ± 9, and 57% died. All patients were admitted for trauma-related injury suffering blast, abrasive injuries or burns. Mortality among patients with signs of sepsis was 100%, and only in one of them was empirically antifungal therapy started; in the others antibiotic treatment was directed. Among patients without signs of sepsis, the survivor was treated with amputation where mucoral infection was isolated. Procalcitonin rose in all patients with signs of sepsis.

Conclusion Cutaneous mucormycosis is less common than other clinical forms, most frequently seen in immunocompetent patients but potentially lethal if treatment is not rapid. Patients at risk are those with disruption of the normal protective cutaneous barrier. In these patients, if signs are of sepsis it is very important to suspect the possibility of infection by Mucor and initiate empiric antifungal treatment immediately to avoid high mortality. Surprisingly, in our series, determination of procalcitonin showed high levels in spite of not having value in fungal infection.

P89 Low-pathogenicity mycoplasma species induce immunoparesis and are highly prevalent amongst patients with ventilator-associated pneumonia

TJ Nolan1, N Gadzy2, TP Hellyer3, K Templeton4, R McMullan2, J McKenna1, A Conway Morris5
1University of Edinburgh, UK; 2NHS Lothian, Edinburgh, UK; 3Newcastle University, Newcastle, UK; 4Queens University, Belfast, UK; 5University of Cambridge, UK

Introduction Ventilator-associated pneumonia (VAP) remains a significant problem within ICUs. There is a growing recognition of the impact of critical-illness-induced immunoparesis on the pathogenesis of VAP, but the mechanisms of this immunoparesis remain incompletely understood. We hypothesised that, because of limitations in their routine detection, Mycoplasma species are more prevalent amongst patients with VAP than previously recognised, and that these organisms potentially impair immune cell function.

Methods Two cohorts [1,2], totalling 159 patients, were recruited from 12 UK ICUs; all patients had suspected VAP and undergo bronchoscopy and bronchoalveolar lavage. VAP was defined as growth of organisms at >10⁴ CFU/ml on conventional culture. Thirty-six healthy donors underwent lavage for comparison. Samples were tested for Mycoplasma species (Mycoplasma and Ureaplasma spp.) by PCR, and positive samples underwent sequencing for speciation. Additionally, healthy donor monocytes and macrophages (MDM) were exposed to Mycoplasma salivarium and their ability to respond to lipopolysaccharide and undertake phagocytosis was assessed.

Results Mycoplasmataceae were found in 48% of patients with VAP, compared with 14% of patients without VAP (P < 0.0001). Patients with sterile lavage had a similar prevalence to healthy donor lavage (10 vs. 8%, P = 0.54). The commonest organism identified was M. salivarium. Human blood monocytes and MDM incubated with M. salivarium displayed impaired cytokine responses to lipopolysaccharide and MDM demonstrated impaired phagocytosis.

Conclusion This study demonstrates a high prevalence of Mycoplasmataceae amongst patients with VAP, with a marked lower prevalence amongst patients with suspected VAP in whom subsequent cultures refuted the diagnosis. The commonest organism found, M. salivarium, is able to profoundly impair the functions of key immune cells and thus suggests that Mycoplasmataceae may contribute to VAP pathogenesis.

References
Gram-positive bacteria (n = 24, 30%); Staphylococcus aureus (n = 16, 20%), Enterococcus faecalis (n = 4, 5%), Staphylococcus epidermidis (n = 3, 4%), Gram-negative (n = 43, 53%); klebsiella sp. (n = 13, 16%), Pseudomonas aeruginosa (n = 7, 9%), Escherichia coli (n = 7, 9%) and fungi (n = 5, 6%); candida sp. (n = 2, 3%). Candida albicans (n = 1, 1%); Candida dublina (n = 1, 1%). The commonly prescribed antimicrobials were piperacillin/tazobactam (n = 32, 40%), vancomycin (n = 30, 37%), polymyxin B (n = 23, 28%), cefepime (n = 16, 20%), meropenem (n = 12, 15%), cefuroxime (n = 8, 10%), ciprofloxacin (n = 6, 7%), tigecycline (n = 6, 7%), ampicillin (n = 5, 6%), clindamycin (n = 4, 5%), chloramphenicol (n = 4, 5%), oxacillin (n = 4, 5%) and others (n = 32, 28%). There was 75% (n = 46) infection during hospitalization in the unit. Approximately 32% of infections were caused by multidrug-resistant pathogens, although there was efficiency of 81% in the proper use of initial antimicrobials.

**Conclusion** We conclude that infection is prevalent even in CICU, and that the microbiological profile is quite diverse, as well as the antibiotics. This allows us to better understand the profile of this kind of unit.

**P93**
Is carriage of multidrug-resistant organisms a risk factor for nosocomial infections in an infectious diseases ICU?
M Lupu1, M Florea2, L Herbelt3, A Petrovan4, A Binder1, A Todor1, A Cioara1, A Coaria1
1University of Medicine and Pharmacy, Cluj-Napoca, Romania; 2Teaching Hospital of Infectious Diseases, Cluj-Napoca, Romania; 3Ian Chiricuta Institute of Oncology, Cluj-Napoca, Romania

**Introduction** The objective was to evaluate whether asymptomatic carriage of methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant enterococci (VRE) and extended-spectrum beta-lactamase producing Gram-negative bacilli (ESBL-GN) on admittance to the ICU of the University Hospital of Infectious Diseases Cluj-Napoca, Romania is a risk factor for infection due to these multidrug-resistant organisms (MDRO) during hospitalization.

**Methods** A prospective study during a 6-month period (June to November 2014), including all adult patients admitted to our ICU. All patients were screened on admittance for nasal MRSA, intestinal VRE and ESBL-GN carriage. Patients admitted with any localization of infections due to these organisms were excluded. Patients were monitored for developing nosocomial infections due to MDRO during hospitalization. We evaluated previous colonization as a risk factor for future infections. We used bioMerieux selective chromogenic media for MDRO for screening and Vitek2Compact for identification. Statistical analysis was performed with chi-square test and univariate analysis.

**Results** From 119 screened adult patients, 65 women (54.6%), average age 67 years, we had at screening on admittance into the ICU: 14 positive MRSA (11.8%), 63 positive ESBL-GN (52.9% – 41 strains of Escherichia coli, 26 strains of Klebsiella sp., 11 strains of Proteus mirabilis and one strain of Enterobacter cloacae) and 35 positive VRE (29.4% – 33 strains of Enterococcus faecium and two strains of Enterococcus faecalis) without concomitant infection with these MDRO. The average duration of ICU stay was 7.32 days. During hospitalization, 14 patients (11.8%) developed nosocomial infections due to MDRO. Colonization with MDRO preceded nosocomial infections in: one of four patients with MRSA-positive blood cultures (P = 0.96), seven of eight patients with ESBL-GN infections (P = 0.10) and three of four patients with VRE urinary tract infections (P = 0.14). Although not statistically significant, owing to the low number, most patients who developed infections with ESBL-GN had previous intestinal colonization.

**Conclusion** The carriage of MDRO in ICU-admitted patients is important, especially for ESBL-GN. The incidence of nosocomial infections with MDRO in the ICU is high. ESBL-GN intestinal colonization could be a risk factor for nosocomial infections but further studies are needed to confirm this.

**P94**
Patient epidemiology in a level II hospital ICU and how main nosocomial infections affect morbidity and mortality
M Muñoz1, E Yuste1, O Moreno1, R Fernandez2, R Ramirez3
1Hospital Universitario San Cecilio, Granada, Spain

**Introduction** We describe the type of patient and the main nosocomial infections in a level II hospital ICU unit, 18 beds (12 polyvalent-general, six intensive).

**Methods** We used the ENVIN-HELICS database and made statistical calculations for all patients admitted to the ICU between 1 October 2012 and 30 September 2013 using SPSS v15.

**Results** Patients admitted (1,126); 65.1% were male; mean age 61.72 (SD ±15.8); CI (60.7 to 62.7); mean APACHE II 12.6 (SD ± 8.42), CI (12.12 to 13.11); and a mean time stay of 4.84 days (SD ± 26). In total, 60.9% were provided from the community. A total of 44.1% were coronary, 2.84% trauma and 53.02% medical- surgical patients. A total of 29.8% had antibiotic therapy in the ICU, 20% had it before incoming. In total, 18.38% were treated with artificial airway (MV, tracheostomy). In total, 54.09% used a urinary catheter and 38.8% needed a central venous catheter. Fifteen percent of patients had some kind of surgery before
admission; 4.8% required the extrarenal depuration technique. In total, 497 patients (44.1%) were coronary, 49.5% male, mean age 66.18 (SD ±12.6), CI (64.88 to 67.48); mean APACHE II 19.74 (SD ±6.1), CI (9.1 to 10.3); and a mean time stay of 3.62 days (SD ±4.7), CI (3.1 to 4.1). Mortality in this group was 3.7%. In 61.9% of cases the diagnosis of admission was AMI, 16% arrhythmia and 11.6% unstable angina. Of patients, 629 were polyvalent (55.8%), 53.85% male, mean age 58.05 (SD ±17.2), CI (56.7 to 59.4); mean APACHE II 14.6 (SD ±9.1), CI (13.8 to 15.3); and a mean time stay of 4.64 days (SD ±7.7), CI (4 to 5.25). Mortality was 11.6%. In 33.2% the cause of income was digestive, 23.2% acute or chronic exacerbated respiratory failure, 12.4% severe sepsis/septic shock and 10.1% postoperative cardiovascular surgery. The incidence density (ID) of catheter-related bacteremia was 5.5, 92.8% from the fourth day of ICU admission; ID of ventilator-associated pneumonia (VAP) was 5.94, 88.9% since the fourth day; and ID of urinary tract infections (UTI) related to urinary catheter was 2.88, 80% of them since the fourth day. From all patients who developed intra-ICU infections, mean APACHE II in admission was 21.3 (SD ±9.6) with a mean time stay of 23.4 days (SD ±12.9) and a mortality percentage of 19.6%.

Conclusion In our ICU the main cause of admission was the polyvalent patient, who is younger and has more severity with not much difference in mean time of stay compared with the coronary patient. The intra-ICU infections provide an increase of morbi-mortality risk and consumption of resources.

P95
Emergence of isolates that are intrinsically resistant to colistin in critically ill patients: are we selecting them out?
MN Sivakumar, M Hrisham, V Nandakumar, T Gopinathan
Koval Medical Center and Hospital, Coimbatore, India

Introduction Poor infection control practices along with irrational usage of antibiotics lead to emergence of multidrug-resistant (MDR) organisms. Increasing use of colistin for treating MDR infections leads to selection of organisms that are intrinsically resistant to colistin. There are limited Indian literatures which evaluated the incidence of intrinsically resistant isolates to colistin in critically ill patients. Our study aimed to investigate the incidence of true pathogen or colonizer with the prior antibiotic exposure and patient’s clinical outcome.

Methods The prospective, cross-sectional study was carried out from March 2013 to April 2014. Clinical samples included culture positivity for isolates intrinsically resistant to colistin from patients who were admitted to the ICU or had a prior ICU stay in the same admission.

Results A total of 93 unusual Gram-negative rods were isolated from 76 patients. This included 19.4% (n = 18) Serratia marcescens, 12.9% (n = 12) Stenotrophomonas maltophilia, 14% (n = 13) Burkholderia cepacia, 24.7% (n = 23) Proteus mirabilis, 17.2% (n = 16) Morganella morganii, 9.7% (n = 9) Elzabethkingia meningoseptica and 2.1% (n = 2) Providencia species. A total of 68.4% (n = 52) patients had prior exposure to either colistin or carbapenem or both. In total, 71% (n = 66) of the total isolates from patients had previous antibiotic exposure. Among the total 93 intrinsically resistant isolates to colistin, 37.6% (n = 35) of isolates from all clinical sources (endotracheal, pus, urine and blood samples) were true pathogens and the remaining 62.3% (n = 58) were colonizers. There was a statistically significant increase in length of ICU stay and duration of hospitalization in the presence of true pathogen.

Conclusion Selection pressure due to extensive use of higher antibiotics may lead to emergence of intrinsically resistant isolates, which narrows the therapeutic options in the ICU. Our study emphasizes the paramount importance of establishing clinical relevance of these organisms before treating them as true pathogens. This calls for judicious use of higher antibiotics, implementation of an antibiotic stewardship program and strict infection control practices.

In vitro antimicrobial susceptibility of fosfomycin against organisms isolated from various clinical specimens: a multicentre trial from Kolkata
A Chakraborty, S Roy, S Chakraborty, A Datta, A Kar
Medica Superspeciality Hospital, Kolkata, India

Introduction In the era of rising prevalence of serious infections caused by multidrug-resistant (MDR) organisms and the paucity of in-flow of newer antimicrobial agents, the relatively older antibiotics that had been left out of clinical practice for various reasons are now being increasingly considered as the potential agents to combat such infections. Fosfomycin, known for almost four decades, has a broad spectrum of activity against several Gram-negative and Gram-positive bacteria.

Methods This study, conducted in the Microbiology Department of Medica Superspecialty Hospital between July and November 2014, was aimed at testing the in vitro susceptibility of fosfomycin against isolates identified from various clinical specimens from different parts of Kolkata. After confirming the identity and antibiotic by Microscan Autoscan 4, the isolates were tested for fosfomycin sensitivity by the disk diffusion test. MIC values were interpreted in accordance with the currently recommended Clinical and Laboratory Standards Institute (CLSI) criteria for urinary tract isolates of Escherichia coli and Enterococcus faecalis and the European Committee on Antimicrobial Susceptibility Testing (EUCAST) criteria for Enterobacteriaceae and Staphylococcus aureus.

Results Out of the 1,895 isolates tested, fosfomycin displayed an overall in vitro susceptibility against 90%, but only 64% against MDR strains. Among the MDR organisms nearly 78% of E. coli and 70% of Klebsiella spp. and 40% of MRSA isolates showed provisional MICs in the sensitive range while among the sensitive strains fosfomycin showed around 92% susceptibility. Our study results were comparable with the results obtained from an Indian study published from CMC Vellore in 2013 showing a fosfomycin susceptibility of around 75% among MDR uropathogenic E. coli.

Conclusion Being a broad-spectrum bactericidal agent usable both orally and parenterally with low toxicity profiles and lesser prevalence of cross-resistance with other antimicrobials, fosfomycin can be an alternative to other broad-spectrum agents to treat uncomplicated infections as well as in the case of infections with MDR organisms where treatment options are very few. This study possibly reveals a much-needed solution for the rising carbapenem resistance and also for the treatment of infections with such MDR pathogens, thereby bringing down the length of stay in hospital, cost of therapy and suffering on the part of the patients.

P97
Antibiotic synergy testing for multidrug-resistant Gram-negative pathogens in a Greek ICU
E Douka, E Perivoliot, E Kraniotaki, M Nepka, C Routsi, K Fountoulis, A Skoutelis, S Zakyntinos
Evangelismos General Hospital, Athens, Greece

Introduction The emergence of multidrug-resistant (MDR) pathogens is a major cause of infection-related mortality among critically ill patients. The synergistic effect between commonly used antibiotics against difficult to treat nosocomial MDR Gram-negative strains, if present, could provide a viable option as an alternative therapy. The aim of this study was to investigate the potential of antibiotic synergy against MDR A. baumannii, K. pneumoniae and P. aeruginosa strains, isolated from critically ill patients in a Greek ICU.

Methods We tested 59 A. baumannii, 41 K. pneumoniae and 64 P. aeruginosa strains, isolated during the period 2010 to 2013. All strains were resistant to carbapenem and showed reduced susceptibility or resistance to tigecycline or colistin (MIC >2), in accordance with CLSI guidelines. We evaluated double-drug combinations of carbapenem (CRB)/colistin (COL), tigecycline (TG)/COL, rifampicin (RIF)/COL, CRB/gentamicin (GEN), CRB/amikacin (AMK) for A. baumannii, TG/COL,
CRB/COL, piperacillin–tazobactam (PIP/TAZ)/GEN, CRB/GEN for K. pneumoniae and AMK/PIP/TAZ, AMK/aztreonam (AZT), AMK/cefepime (CEF), AMK/CRB and CRB/COL for P. aeruginosa strains. In order to perform synergy tests, the E-test methodology (BioMerieux, Marcy l’Etoile, France) was used. Synergy was defined as a fraction inhibitory concentration (FIC) index ≤0.5, additive effect 0.5 to 1, indifferent or antagonistic effect >2 (Lorian definition).

Results Against 59 MDR A. baumannii strains, the synergy effect of CRB/COL was 35.9%, RIF/COL 38.9%, CRB/GEN 22%, CRB/AMK 20.3% and TG/CEL 19.3% respectively. Against 41 K. pneumoniae strains, synergy rates were: CRB/COL 43.9%, CRB/GEN 31.7%, PIP/TAZ/GEN 29.2% and TG/COL 24.4% respectively. Against 64 P. aeruginosa strains, synergy rates were: AMK/PIP/TAZ 64.6%, AMK/AZT 64.6%, AMK/CEF 58.3%, CRB/COL 52%, AMK/CRB 25%.

Conclusion The most effective combination for both the A. baumannii and K. pneumoniae strains tested was CRB/COL. The next most effective combination was RIF/COL and CRB/GEN respectively. No competitive effect was observed for RIF/COL combination in all cases tested. The most effective combinations for P. aeruginosa strains were AMK plus PIP/TAZ or AZT or CEF. The next most effective combination was CRB/COL. We recommend implementation of an antibiotic synergy test for MDR pathogens as a routine antimicrobial test in the hospitals’ microbiology laboratories. Especially for critically ill patients, since some combinations seem to excel. Further studies are needed for the correlation of these combinations with clinical efficacy.

P98 Development of antibiotic treatment algorithms based on Gram stain to restrict use of broad-spectrum antibiotics in the treatment of ventilator-associated pneumonia: a retrospective analysis
J Yoshimura, T Kiguchi, A Matsushima, S Fujimi
Osaka General Medical Center, Osaka, Japan

Introduction Ventilator-associated pneumonia (VAP) is a common and serious problem in ICUs. Several studies have been conducted to determine the effectiveness of Gram stain of tracheal aspirates for diagnosing VAP. However, the effectiveness for predicting causative microorganisms and guiding appropriate initial antibiotic therapy has not been evaluated. The purpose of this study is to determine whether Gram stain of tracheal aspirates can guide appropriate initial antibiotic therapy for VAP.

Methods We retrospectively assessed two hypothetical empirical antibiotic treatment algorithms for VAP on a 18-bed ICU. Data on consecutive episodes of microbiologically confirmed VAP were collected over a period of 22 months and divided into a derivation (1 February 2013 to 30 November 2013) and validation (1 December 2013 until 15 November 2014) cohort. We constructed two algorithms in the derivation cohort. One is a local ecology-based algorithm (LEBA), according to clinical risk factors for MDR and susceptibility results in our hospital. The other is a Gram stain-based algorithm (GSBA). The selection of antibiotics on GSBA was directed against pathogens predicted from the results of bedside Gram staining of tracheal aspirates collected just before antibiotic therapy. Subsequently, LEBA and GSBA were retrospectively reviewed and compared with actually prescribed antibiotics in the validation cohort.

Results The first 50 VAP episodes made up the derivation cohort and the subsequent 50 VAP episodes the validation cohort. Antibiotic coverage rates by applying LEBA and GSBA were identical (96% vs. 96%). GSBA proposed more narrow spectrum therapy as compared with LEBA (P <0.001). GSBA recommended carbapenems in significantly less episodes than LEBA (P <0.001) and the same episodes as actually prescribed initial therapy (P = 1). However, there was significant increase of antibiotic coverage rates in GSBA compared with the actually prescribed initial therapy (96% vs. 78%, P = 0.0015).

Conclusion Antibiotic coverage rates on GSBA were comparable with LEBA. The use of GSBA would result in a significant reduction of the administration of broad-spectrum antibiotics. Bedside Gram staining may be useful to guide appropriate initial antibiotic therapy for VAP.

Protective effect of a fecal incontinence management system against bacteremia for out-of-hospital cardiac arrest patients undergoing extracorporeal membrane oxygenation

S Kikuta, R Miki, S Ishihara, S Nakayama
Hyogo Emergency Medical Center, Chuo, Kobe, Hyogo, Japan

Introduction
Recently, extracorporeal cardiopulmonary resuscitation (ECPR) has become a common measure against cardiopulmonary arrest. In cases with ECPR, we usually insert cannulae for extracorporeal membrane oxygenation (ECMO) via the femoral artery and vein. However, the cannulation site is often contaminated by feces due to incontinence. Moreover, patients tend to be compromised by hypothermia due to the target temperature management, so we often experience central line-associated bloodstream infection of patients undergoing ECMO. We investigated the protective effect of a fecal incontinence management system (FMS) against bacteremia in patients undergoing ECMO.

Methods
We studied 41 consecutive patients undergoing ECMO for out-of-hospital cardiac arrest (OHCA) between April 2010 and May 2014. Patients were divided into two groups according to the use or no use of FMS (Flexi-Seal™). Patients who died within 48 hours or whose cannulae for ECMO were removed within 48 hours were excluded. Patients’ characteristics, underlying disease, target temperature management, prophylactic antibiotic use and incidence of bacteremia during admission were recorded and analyzed retrospectively.

Results
Among 41 patients, 15 (37%) underwent FMS. There was no difference in age, sex, underlying disease, target temperature management, and prophylactic antibiotic use between two groups. Mean duration of ECMO was 4 days in both groups. The incidence of bacteremia was none in the group with FMS and five (19%) in the group without FMS. Within five cases of bacteremia, three were caused by enterobacterium.

Conclusion
FMS may be protective against bacteremia for OHCA patients undergoing ECMO.

Methicillin-resistant Staphylococcus aureus in the ICU: risk factors and a predictive model to detect it at ICU admission

F Callejo-Toro, JMI Eros, S Osca-Echeverri, P Olachea, M Palomar, F Alvarez-Lemara, Envin-Helics Study Group
1Hospital Universitario de Burgos, Spain; 2Hospital Clínico Universitario de Valladolid, Spain; 3Hospital de Galdakao-Usansolo, Galdakao, Spain; 4Hospital Arnau de Villanova, Lleida, Spain; 5Hospital del Mar, Barcelona, Spain

Introduction
Being capable of predicting MRSA on ICU admission is crucial to enhance infection control and to avoid inappropriate empirical treatment. Two objectives were studied: to describe risk factors for MRSA colonization/infection (MRSA-C/I) once admitted to the ICU; and to develop a predictive model at ICU admission, based on easy-to-obtain admission factors.

Methods
Data were collected prospectively from 69,894 patients admitted consecutively (stay >24 hours) to 147 Spanish ICUs participating in the National Surveillance Study of Nosocomial Infections in ICU registry (ENVIN) during April to June 2006 to 2010. Univariable and multivariable analysis was performed for both objectives but we used only easy-to-obtain variables for the predictive model exclusively from those admitted in 2010 (n = 16,950; 2/3 for analysis and 1/3 for subsequent validation).

Results
In the 2006 to 2010 period, 1,046 were C/I by MRSA (note that relative risks are not included due to space limitations). First objective: previous antibiotic, APACHE II score >18, skin-soft tissue or posturgical superficial skin infections, trauma or medical patient, age >65 (especially >75), urinary catheter and admitted from a long-term care facility were independent risk factors for MRSA-C/I in ICU. Multicolonization increased significantly the risk of MRSA-C/I and immunodeficiency and gender male emerged as protective factors.

Conclusion
Independent risk factors for MRSA-C/I at ICU admission could not be based merely on clinical–demographic risk factors. Taking into account local particularities and combining risk factors with a rapid laboratory test might be the most effective way forward.

Novel influenza A antibodies reduce severity of secondary pneumococcal pneumonia after influenza infection in mice

KF Van der Sluijs, F Van Someren Greve, MD De Jong, MJ Schultz, NP Juffermans
Academic Medical Center, Amsterdam, the Netherlands

Introduction
Secondary bacterial pneumonia after influenza infection can cause severe disease with a high mortality. Recently, a new group 2 influenza A antibody (AT10_002) has been developed, which binds to multiple H3 and H7 subtypes. In a mouse model of primary influenza infection, treatment with AT10_002 as a fusion antibody protects against lethal infection, and reduces loss of bodyweight [1]. We hypothesized that treatment with AT10_002 reduces weight loss, lung injury and bacterial outgrowth, in a mouse model of viral infection followed by secondary pneumococcal infection.

Methods
Male C57Bl/6 mice were intranasally inoculated with 400 TCD50 Influenza A (H3N2). Two days after infection, mice were injected with either AT10_002 i.v. (n = 8) or a control antibody (n = 7). After 7 days, both groups were intranasally inoculated with 5×10^5 S. pneumoniae type 3 and were sacrificed 18 hours later. Outcome measures were weight loss, wet lung weight, cell count in bronchoalveolar lavage fluid (BALF), and colony-forming units (CFUs) in lung homogenate. Data are represented as medians, and treatment groups are compared using nonparametric tests.

Results
Mice receiving AT10_002 showed significantly lower weight loss at the time of sacrifice compared with the control group (+1% vs. −12% change in weight; P = 0.0003). Also wet lung weight was lower (68 vs. 96 mg; P = 0.0003), cell counts in BALF were lower (4.9 × 10^5 vs. 7.0 × 10^5 cells/ml; P = 0.0037) and CFUs in lung homogenate were lower (33 vs. 2.5 × 10^4 CFUs/ml; P = 0.0003) compared with controls.

Conclusion
Early treatment with influenza antibody AT10_002 significantly reduces weight loss, lung injury and bacterial outgrowth,
in a mouse model of influenza infection followed by secondary pneumococcal pneumonia.

Prevalence of viral respiratory tract infections in acutely admitted and ventilated ICU patients: a prospective multicenter observational study
F Van Someren Groene1, F Van der Sluijs1, R Molenkamp1, AM Spoelstra-de Man1, OL Cremer1, RB De Wilde1, PE Spronk1, MD De Jong1, MJ Schultz2, NP Juffermans3
1Academic Medical Center, Amsterdam, the Netherlands; 2VU Medical Center, Amsterdam, the Netherlands; 3University Medical Center Utrecht, the Netherlands; 4Leiden University Medical Center, Leiden, the Netherlands; 5Gelse Hospitals, Apeldoorn, the Netherlands

Introduction The prevalence of viral respiratory tract infections in critically ill patients is uncertain, as well as the optimal diagnostic method to detect these. The aim of this study was to assess the prevalence of viral respiratory tract infections in mechanically ventilated patients, in both the upper and lower respiratory tract.

Methods A prospective observational study was performed in five ICUs in the Netherlands. From September 2013 to April 2014, consecutive acutely admitted, mechanically ventilated patients were included, regardless of diagnosis at admission. Nasopharyngeal (NP) swabs and tracheal aspirates (TA) were collected at intubation, and were tested via multiplex RT-PCR for the following viruses: influenza A and B, parainfluenzaviruses, RSV, human metapneumoviruses, bocaviruses, coronaviruses, rhinoviruses, enteroviruses, parechoviruses and adenoviruses. Viral DNA/RNA copies were expressed by crossing-point (cp) values.

Results In total, 1,499 patients were included, of whom 265 patients (18%) had a viral respiratory tract infection with at least one virus. In 17 patients, two viruses were found; two patients had an infection with three viruses. The most prevalent was parainfluenzavirus-3 (5.7%); 17 patients (1.1%) had an infection with influenza. The lowest prevalence of viral infections occurred in September (12%), the highest in October and February (both 26%). Of the patients tested positive in TA, only 46% also tested positive in NP. The median cp values were not significantly different between TA and NP swabs (31.1 vs 31.6, P = 0.75).

Conclusion The prevalence of viral respiratory tract infections is high in unselected ICU patients. Testing tracheal aspirate in combination with nasopharynx greatly increased detection of viruses, and yields similar cp values. Whether these viral infections are associated with prolonged mechanical ventilation and worse outcomes remains to be determined.

P105
Adequate initial antimicrobial therapy as the factor assessing treatment efficacy in human septic shock
P Szturz1, P Folwarczny1, J Scvancar2, R Kula3, P Ševěk1
1University Hospital and Faculty of Medicine Ostrava University, Ostrava, Czech Republic; 2Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic

Introduction The early identification of severe sepsis and septic shock and early implementation of the SSC bundles were associated with reduced mortality [1]. The failure to initiate appropriate antimicrobial therapy increased mortality of septic shock patients [2]. We hypothesized that the parameter ‘Consensus initial antimicrobial therapy with microbial cultures’ correlates with outcome of septic shock patients.

Methods We analyzed 535 consecutive patients with septic shock (sepsis-induced hypotension persisting despite adequate fluid resuscitation) from the EPOSS database (Data-based Evaluation and Prediction of Outcome in Severe Sepsis), which was developed to monitor and assess treatment efficacy in patient with severe sepsis and septic shock. Patients were admitted to participating ICUs (12 hospitals – 17 high-volume care units) in the Czech Republic from 1 January 2011 to 5 November 2013. Patients were divided into two groups: survivors (n = 274) and nonsurvivors (n = 261).

Results Survivors versus nonsurvivors were similar in: age 65.8 (64.2-67.5) versus 66.5 (64.7-68.3) P = 0.583, men 159 (58.0%) versus 160 (62.0%) P = 0.376, APACHE II score 27 (15 to 40) versus 28 (15 to 40) P = 0.737. Statistically significant differences between survivors versus nonsurvivors were found in the parameter ‘Consensus initial antimicrobial therapy with microbial cultures’ 178 (79.5%) versus 128 (58.4%) P <0.001 and in the parameter ‘Administration antimicrobials within the first hour’ 163 (59.9%) versus 171 (70.7%) P = 0.001. Administration of 30 ml/kg crystalloid for hypotension or lactate 4 mmol/l (3 hours) and application of vasopressors (6 hours) were in both groups without statistically significant differences.

Conclusion We found that correct choice of antibiotics improves outcome of septic shock patients. The choice of empirical antimicrobial therapy depends on complex factors related to the underlying disease, susceptibility of pathogens, patient’s history and clinical syndrome. Adequate initial antimicrobial therapy as an important factor of survival along with suitable initial fluid resuscitation and application of vasopressors should be a priority for healthcare in human septic shock.

Source of MDR infections in an ICU: busting the myth
R Agrawal
FEHI, New Delhi, India

Introduction MDR infections in the ICU are not nosocomial all the time, as perceived commonly. We performed a 2-year retrospective study to analyze the source of culture positivity in a medical ICU and to identify which types of infections are more prevalent.

Methods The data of a 35-bed medical ICU were analyzed from November 2012 to October 2014. The source of culture positivity was divided into three groups: patients admitted from the ER to the ICU who were referred from other hospitals or direct admissions, the second group was patients admitted within the hospital but outside the ICU for the first 48 hours, and the third group was ICU-acquired infections. We also analyzed the data for type of infections, whether Gram-negative, Gram-positive or fungal.

Results There were 1,051 cultures positive in a 2-year period. In total, 46.8% (n = 492) of cultures were already positive on admission, which denotes community-acquired and referred patients from other hospitals. A total of 31.1% (n = 327) of cultures were positive from patients admitted to general wards for more than 48 hours and then transferred to the ICU. Twenty-two percent (n = 232) of cultures were ICU-acquired infections. The data show community-acquired and hospital-acquired infections are the bulk of the culture load in an ICU. This could be attributed to increased surveillance and adherence to infection control practices in the ICU which may not be followed stringently in other parts of the hospital. Overuse of broad-spectrum antibiotics in community and primary care hospitals has resulted in a spurt in growth of resistant infections. This has reached an alarming level in developing countries. Out of total cultures positive 78.3% (n = 822) were Gram-negative infections which included community-based and non-ICU infections.

Conclusion Antibiotic stewardship and strict adherence to infection control protocols in hospitals and guidelines for general practitioners can significantly reduce the load of resistant organisms in the ICU. This may eventually improve patient outcomes and help in preserving the antibiotics for future generations.

Concordance between a new molecular real-time approach and traditional culture in suspected VAP patients
M Clavel1, O Bardaud1, V Moucardel1, MC Ply1, E Karam1, F Meynier1, B François for Valibi Study Group2
1Hospital Dupuytren, Limoges, France; 2UMRS-1092, Hospital Dupuytren, Limoges, France; 3bioMérieux SA, Grenoble, France; “Service de Réanimation, Brivz, France; 4Inserm, Limoges, France
Introduction Early microbiological documentation may reduce attributable mortality and excessive use of broad-spectrum antibiotics in ventilator-associated pneumonia (VAP). Using bronchoalveolar lavage (BAL) and endotracheal aspirates (ETA), we studied a new molecular biology-based approach to detect and quantify bacteria in less than 3 hours. This prospective multicenter trial aimed at comparing the microbiological results obtained using this molecular protocol (easyMAG® system) and semiquantitative culture in suspected VAP.

Methods ETA and BAL samples were consecutively collected during 10 months in adult patients in four ICUs of France. The molecular method includes a preprocessing liguefaction for ETA before DNA extraction. DNAs were extracted using the easyMAG® system. Real-time PCR (qPCR) was run using the ABI7500FastDx PCR instrument. The results presented here concern: Staphylococcus aureus, Pseudomonas aeruginosa and Enterobacteriaceae. Quantification was performed using qPCR standard curves, by converting the cycle threshold to CFU/ml.

Results A total of 125 suspected VAP were included from 122 patients. In total, 125 BAL and 107 ETA were collected. Sex ratio (M/F) was 76%, and CPIS ≥2 was calculated in 74.6% of the suspected patients. Mean ventilation duration before sampling was 6 days. Seventy-eight percent and 65% of the BAL and ETA culture were positive respectively. Correlations between molecular method and culture on BAL and ETA are reported in Table 1.

Table 1 (abstract P107). Concordance between qPCR and culture on BAL/ETA in VAP patients

<table>

Use of Cepheid Xpert Carba-R® for rapid detection of carbapenemase-producing bacteria in critically ill, abdominal surgical patients: first report of an observational study
A Cortegiani1, VRussotto1, P Capuano1, G Tricoli2, DM Geraci2, A Ghodousi1, LSaporto1, G Graziano1, A Giarratano1
University of Palermo, Italy
Introduction Xpert Carba-R® (Cepheid®, USA) is a PCR-based assay for rapid (<1 hour) detection of bacteria carrying carbapenem-resistance genes (KPC, NDM, VIM, OXA-48, IMP-1). The aim of the study is to compare PCR with microbiological cultures in critically ill, abdominal surgical patients.

Methods We performed an observational study at University Hospital ‘P. Giaccone’ Palermo. We enrolled abdominal surgical patients admitted to the ICU with suspected abdominal sepsis or developing sepsis during the ICU stay. We obtained two rectal swab specimens and two drainage samples to perform PCR assay and classic culture tests. We used Cohen’s K to test concordance of results. We considered concordant those results of positive detection of carbapenemase-producing bacteria by both methods (even if a polymeric growth was observed by cultures) or negative results by both methods. Concordance was studied for rectal swab and drainage specimens. Antibiotic susceptibility testing was performed through a semiquantitative method.

Results Eight complete samples sets were collected from seven patients. Seven rectal swab specimens were negative for both PCR and cultures. In one patient a positive culture from carbapenem-resistant P. aeruginosa was detected from the rectal swab resulting negative to PCR. In one patient a positive culture from carbapenem-resistant A. baumannii was detected by culture during result negative to PCR. In two cases a positive result was observed from both PCR and cultures of rectal swab and drainage specimens. Vm and KPC genes were detected in one case and A. baumannii and K. pneumoniae with carbapenem resistance were isolated from cultures. A KPC gene was detected by PCR in the other case, and K. pneumoniae with carbapenem resistance was isolated from cultures. In all other cases a negative result was observed by both PCR and cultures. Cohen’s K of 0.71 (95% CI: 0.21 to 1) was observed for rectal swab and drainage specimens.

Conclusion We need more data to evaluate the performance of PCR for rapid detection of carbapenemase-producing bacteria from rectal swab and drainage of critically ill surgical patients even though its concordance with cultures seems to be good.

P109
Use of an electronic medical record system to improve antimicrobial stewardship
P Allan, M Newman, J Collinson, L Bond, W English
Royal Cornwall Hospital NHS Trust, UK
Introduction Antimicrobial resistance constitutes a growing global threat, driven in part by inappropriate antimicrobial prescribing [1]. Most hospitals implement antibiotic policies to promote antimicrobial stewardship. This audit examined the Royal Cornwall Hospital Trust (RCHT) Critical Care Department’s compliance with the current standard defined in our local antimicrobial policy. This states that all antimicrobial prescriptions are to have an indication and review date recorded [2]. Sequential strategies to improve compliance were introduced prior to re-auditing the effects.

Methods The RCHT Critical Care Department utilizes the Phillips Care Vue electronic patient record. Data from this system were interrogated at three stages to assess our compliance with the trust’s antimicrobial policy. The first data interrogation was performed prior to any intervention, and reflected baseline antimicrobial prescribing habits. The second data interrogation was performed during a period of active antibiotic stewardship promotion. The third data interrogation was performed following the addition of a care bundle to the prescribing module of Care Vue. This daily tick-box prompt reminded clinicians to check that all antimicrobial prescriptions had an indication and review date recorded. The records of all of the patients admitted to the critical care department during the periods of data interrogations were assessed for antimicrobial indication and review date transcription.

Results From the first data interrogation, antimicrobial prescriptions had an indication and review date transcription in 57% and 60% of cases respectively. Following the awareness campaign, the indication and review date transcription rate increased to 78% and 85% respectively. A daily electronic prompt was then added to our care bundle list. The final data interrogation, performed after this intervention, demonstrated that the transcription rates for both the indication and the review date had increased to 96%.

Conclusion We have demonstrated that the use of a daily prompt within an electronic patient record can greatly improve compliance in recording the indication and review date for all antimicrobials. These data support the widespread implementation of an electronic prescribing system where daily reminders are integrated in an effort to improve compliance with antimicrobial stewardship.
P110
Factors associated with survival of ICU patients with pneumonia caused by multidrug-resistant Gram-negative bacteria
M Georgioudou, E Pappa, E Papandreu, H Pavlou, M Eftekarpoulou
KAT-EKA General Hospital Kifisia, Athens, Greece

Introduction
Multidrug-resistant (MDR) bacterial pneumonia is associated with significant morbidity and mortality in severely ill ICU patients. The assessment of factors associated with the onset and clinical course of MDR pneumonia may improve treatment effectiveness. The purpose of this study is to identify factors associated with outcome in mechanically ventilated patients with ventilator-associated pneumonia (VAP) caused by MDR bacteria.

Methods
We studied retrospectively all mechanically ventilated patients treated in the ICU of KAT General Hospital in Athens from 1 January 2011 to 31 December 2013 and showed ventilator-associated pneumonia from MDR Gram-negative bacteria. Standard demographic and clinical data, the causative organisms and outcome were recorded. For statistical significance, chi-square and Student tests were used.

Results
A total of 102 mechanically ventilated patients, 75 men and 27 women, were included in the study. All patients showed VAP caused by MDR bacteria. They were stratified by outcome into survivors and nonsurvivors. ICU mortality was 55%. Gender, cause of admission, the causative microbe, colonization of bronchial secretions and secondary bacteremia had no correlation with outcome. Age and APACHE II score were higher in nonsurvivors (P < 0.01 and P < 0.05, respectively). The time-onset of pneumonia after admission was longer in patients with VAP caused by Klebsiella or Pseudomonas than those with VAP caused by acinetobacter (P < 0.01). Patients with Klebsiella or Pseudomonas pneumonias needed more time on mechanical ventilation than those with pneumonia from acinetobacter (P < 0.01).

Conclusion
VAP caused by MDR bacteria is a leading cause of ICU death. Age and APACHE II score are significant risk factors of death.

Epidemiological cohort study of systemic antifungal therapy for suspected or confirmed invasive candidiasis in the ICU: the Amarcand2 study
CHU Estaimbourg, Clermont-Ferrand, France; 2Paris Diderot University/Bichat Hospital, Paris, France; 3Rennes University Hospital, Rennes, France; 4Cochin University Hospital, Paris, France; 5Amiens University Hospital, Amiens, France; 6Montpellier University Hospital, Montpellier, France; 7Necker University Hospital, Paris, France; 8Saint-Louis University Hospital, Paris, France; 9Tourcoing University Hospital, Tourcoing, France

Introduction
Prescription of antifungal treatments (AFT) in ICUs in case of suspected or confirmed invasive candidiasis (SIC or CIC) has been challenged by different guidelines. The study aimed to describe the epidemiology of the invasive candidiasis (IC), analyze the criteria for the AFT prescription and its changes during patient follow-up.

Methods
A prospective observational multicenter cohort study. Consecutive adult patients with SIC or CIC and treated with systemic AFT were included between October 2012 and September 2013 in 104 French ICUs.

Results
In total, 870 patients were included and 835 evaluable, the IC was confirmed at study inclusion for 291 and suspected for 544 patients. Eventually, the IC was confirmed for 403/835 patients (peritonitis: 177; candidemia: 141; deep candidiasis: 61; mixed infection sites: 24). Candida albicans was the main pathogen (67%), then C. glabrata (14%). At inclusion, CIC were treated with caspofungin (Cas); 55%, and fluconazole (Flu); 34%, whereas these antifungals were administered to 46% and 45% of SIC, respectively. Patients with SIC were more severe than those with CIC. The two main criteria for initiating empirically an AFT were a central venous catheter (79%) and severe septic shock (70%). The rate of change of the initial AFT was higher in the CIC group (49%) than in the SIC group (33%, P < 0.0001). In the CIC group, it was mostly for changing the antifungal agent (de-escalation Cas → Flu in half of the patients) based on mycological tests results. In the SIC group, the AFT was modified almost as often for changing the drugs (including 22% de-escalation Cas → Flu) as for stopping the AFT. The 28-day mortality of candidiasis was 42% in cases of C. glabrata, 40% in cases of C. albicans, and 20% in cases of C. parapsilosis. Among survivors, the median duration of treatment was 17 to 21 days according to the infection site in cases of CIC, and 10 days in cases of SIC.

Conclusion
French ICU patients are treated with antifungal agents selected according to the candidiasis severity, contrary to ESCMID guidelines which recommend initiating with echinocandins regardless of severity. As recommended, the therapy was secondarily adapted to microbiological results.

Micafungin concentrations 100 mg daily in plasma and burn eschars in patients with severe burn injuries
A Agrifoglio1, MJ Asensio1, M Sánchez1, B Galván1, E Herrera1, L Cachafeiro2, E Perales3, S Luque1, A García de Lorenzo1
1La Paz/IdiPAZ University Hospital, Madrid, Spain; 2Hospital del Mar, Barcelona, Spain

Introduction
Micafungin (MCF) is an echinocandin agent with broad activity against Candida spp., which are frequently isolated in blood and eschar cultures of burned patients, who present different pharmacokinetics (PK) characteristics. Due to the limited information about its PK, we investigate MCF levels in plasma and burn eschar tissue in this population.

Methods
A PK study of MCF at standard dosage (100 mg/day). Cmax (end of the infusion) and Cmin (before next dose) plasma levels of MCF were obtained after first dose and at steady state (days 4 and 5 of therapy); and on day 5 in eschars (1 to 3 hours after infusion). They were measured by HPLC. Spearman’s rho test was used for bivariate correlations between MCF exposure and patient’s clinical factors.

Results
There were 10 patients (eight men; age: 18 to 77 years). Patients’ characteristics and PK are shown in Table 1. A high interindividual variability was observed in the concentrations of MCF. Peak plasma concentrations after the first and repeated doses of MCF were inversely correlated with % burned TBSA (Spearman’s r = −0.695 and −0.750 (P <0.05, respectively), but not with the time from burn injury. MCF concentrations in burn eschars were not correlated with % burned TBSA. MCF was well tolerated. One patient had candidemia. The crude mortality was 40%.

Conclusion
This is the largest PK study of 100 mg daily of MCF in severely burned critically ill patients. The inverse correlation between MCF exposure and % burned TBSA suggests that patients with large burned TBSA may need higher doses of MCF. Nevertheless, MCF levels in plasma and burn eschar tissues after the first and multiple doses were above the MIC90 against most clinically important Candida species.

Tedizolid Clearance by in vitro continuous renal replacement therapy model
SJ Lewis, L Switaj, BA Mueller
University of Michigan, Ann Arbor, MI, USA

Introduction
Tedizolid is an oxazolidinone antibiotic approved to treat acute bacterial skin and soft tissue infection and is under investigation...
for treatment of nosocomial pneumonia, common in critically ill patients with acute kidney injury. There are limited data on tedizolid disposition in continuous renal replacement therapy (CRRT). This study’s purpose was to assess continuous hemofiltration (CHF) and continuous hemodialysis (CHD) influence on tedizolid clearance.

Methods Validated, bovine blood-based, in vitro CHF and CHD models were used with six new HF 1400 (polysulfone) and six new Multiflow 150 (AN 69) hemodiafilters. Tedizolid’s transmembrane clearances (CLTM) during CHF and CHD were assessed by measuring sieving (SC) and saturation (SA) coefficients at various ultrafiltrate (Quf) (1, 2, 3 l/hour) and dialysate flow rates (Qd) (1, 2, 3 and 6 l/hour), using a blood flow rate (Qb) of 200 ml/minute. Tedizolid adsorption was tested in a 1 l recirculating CHF model at Quf of 2 l/hour and Qb of 200 ml/minute over 4 hours. Adsorption (%) was calculated after correcting for the flow rate (Qb) of 200 ml/minute. Urea was added as a control in all experiments. For each assay, run in triplicate, one 200 mg tablet of tedizolid phosphate was crushed, dispersed in water, drained under gravity through one of two types of NG tubes (type 1, Kangaroo Nasogastric Feeding Tube, 10 Fr 43” (109 cm); type 2, Salem Sump Dual Lumen Stomach Tube, 18 Fr/CH (6.0 m) 48” (122 cm)), and collected for tube passage. The prespecified limit for tedizolid phosphate in recovery samples was 90 to 110% of the dose. Limits were also specified for levels of certain impurities.

Results Urea SC and SA were ~1 in all experiments. In CHF, mean tedizolid SC ranged from 0.52 to 0.57 for HF1400 and from 0.50 to 0.54 for M150. CLTM did not differ between filter types for Quf of 1, 2, and 3 l/hour. In CHD, mean tedizolid SA ranged from 0.46 to 0.56 for HF1400 and from 0.38 to 0.44 for M 150. Tedizolid CLTM with the HF1400 was higher than M150 values at Qd of 6 l/hours (P<0.02). Tedizolid exhibited irreversible adsorption within 10 minutes. See Figure 1.

Conclusion Tedizolid’s CLTM is dependent on hemodiafilter type and Qd for CHD and Quf in CHF. At conventional CRRT rates, tedizolid CLTM appears modest relative to total body clearance and is unlikely to require dose adjustments. CRRT adsorption in the clinical setting is likely less than what we observed in this in vitro, continuously recirculating blood model.

Stability of crushed tedizolid phosphate tablets for nasogastric tube administration
G Kennedy1, J Osborn1, S Flanagan1, N Alsaday2, S Bertolami2
1Cubist Pharmaceuticals, Lexington, MA, USA; 2Cubist Pharmaceuticals, San Diego, CA, USA

Introduction Tedizolid phosphate, a novel oxazolidinone antibacterial prodrug recently approved by the US Food and Drug Administration for the treatment of acute bacterial skin and skin structure infections, is available as oral (that is, tablets) and intravenous formulations. The clinical pharmacokinetics of tedizolid, the active moiety of tedizolid phosphate, are similar when orally administered tedizolid phosphate is given as powder in a capsule or as tablets. This suggests that crushing tablets prior to administration is unlikely to alter tedizolid pharmacokinetics, provided no drug is lost during administration. To determine whether the expected dose of tedizolid phosphate can be delivered via nasogastric (NG) tube in critically ill patients who have difficulty swallowing, this study evaluated the stability and recovery of tedizolid phosphate 200 mg tablets after crushing, dispersion in water, and passage through an NG tube.

Methods For each assay, run in triplicate, one 200 mg tablet of tedizolid phosphate was crushed, dispersed in water, drained under gravity through one of two types of NG tubes (type 1, Kangaroo Nasogastric Feeding Tube, 10 Fr 43” (109 cm); type 2, Salem Sump Dual Lumen Stomach Tube, 18 Fr/CH (6.0 m) 48” (122 cm)), and collected for recovery analysis by high-performance liquid chromatography with UV detection. To analyze the chemical stability of the crushed tablet dispersed in water, the aqueous preparation was assayed initially after refrigeration and again after 4 hours at room temperature, without NG tube passage. The prespecified limit for tedizolid phosphate in recovery samples was 90 to 110% of the dose. Limits were also specified for levels of certain impurities.

Results The average and individual recovery values of tedizolid phosphate were within 90 to 110% of the 200 mg dose when crushed tablets, dispersed in water at room temperature, were transferred through the 2 NG tubes (type 1: 95.8%; type 2: 93.6%). There was difficulty swallowing, this study evaluated the stability and recovery of tedizolid phosphate 200 mg tablets after crushing, dispersion in water, and passage through an NG tube.
Conclusion The stability and recovery of tedizolid phosphate were not influenced by crushing the tablets and passing through an NG tube. Therefore, administration of crushed tedizolid phosphate tablets to patients is unlikely to alter the pharmacokinetics of tedizolid compared with whole tablets.

Antiviral prophylaxis inhibits cytomegalovirus reactivation in critical illness
NJ Crowley1, A Owen1, J Millar1, SC Shiels1, RL Woolley2, NJ Ives2, H Osman1, P Moss1, JF Bion1
1University Hospital Birmingham, UK; 2University of Birmingham, UK

Introduction Reactivation of latent cytomegalovirus (CMV) can lead to viremia or CMV disease and has been detected in up to 30% of critically ill patients without prior history of immune suppression. However, the clinical importance of this observation remains unclear. We report a proof-of-concept randomised controlled trial of two antiviral drugs in intensive care patients to determine their impact on CMV reactivation.

Methods We conducted a single-centre randomised controlled study of high-dose valaciclovir or low-dose valganciclovir prophylaxis, as compared with standard care, in CMV seropositive patients in the ICU at Queen Elizabeth Hospital Birmingham, UK. Patients were excluded if CMV seronegative. Study participants randomised to a study drug received either 450 mg valganciclovir daily enterally (or ganciclovir if CMV seronegative). Study participants randomised to a study drug...

Adsortion of amikacin during continuous venovenous haemofiltration in a swine model of acute renal failure

**Introduction** In vitro studies suggest that there is significant adsorption of amikacin, netilmicin, gentamicin and tobramycin to polyacrylonitrile haemofilter. This occurs rapidly and has the potential to substantially reduce the peak aminoglycoside concentration, which will will reduce efficacy [1]. However, whether significant adsorption occurs in vivo is unknown. We therefore carried out a controlled in vivo study of the effect of amikacin adsorption by polyacrylonitrile filters during haemofiltration, using a porcine model of acute renal failure.

**Methods** A porcine model of acute renal failure was created by bilateral ligation of the renal arteries and veins. Eight pigs underwent haemofiltration using a 0.6 m² polyacrylonitrile filter, blood flow 200 ml/minute, ultrafiltration rate 1,000 ml/hour. All ultrafiltrate was returned to the pigs via a separate venous catheter so that any elimination of amikacin by haemofiltration could only be due to adsorption. Another eight pigs underwent sham haemofiltration in which blood was pumped through a haemofilter circuit without a haemofilter and without ultrafiltration. Both groups of pigs were given intravenous amikacin, 15 mg/kg body weight over 30 minutes, and blood samples were taken from the arterial limb of the haemofilter circuit at 0, 5, 10, 15, 20, 25, 30, 40, 50, 60, 75, 90, 105, 120, 150 and 180 minutes after the start of the amikacin administration to assay amikacin concentrations.

**Results** Post-distribution peak concentration of amikacin was slightly, but significantly, lower in the CRRT group than that in sham group (55.0 ± 4.5 vs. 61.1 ± 5.9 mg/l, P <0.05).

**Conclusion** This study shows that the effect of adsorption by polyacrylonitrile haemofilters on in vivo amikacin peak concentrations is small, and less than would be expected from in vitro data.

**Acknowledgements** This work was supported by a grant from the Hong Kong Research Grants Committee, CUHK 4644/08M.

PK/PD of single-dose amikacin in emergency department patients with severe sepsis/shock: should we apply the ICU-based higher loading dose?

**Introduction** Studies in the ICU showed that a single amikacin dose of ≥25 mg/kg should be used in conditions of increased distribution volume (Vd) such as severe sepsis/shock [1]. However, no data are available for emergency department (ED) patients in the early phase of sepsis/septic shock. The purpose of this study was to determine whether a single amikacin dose of 25 versus 15 mg/kg results in PK/PD target attainment for ED patients.

**Methods** ED patients with severe sepsis/shock were randomly treated with a single amikacin dose of 25 versus 15 mg/kg. Blood samples were collected at +1 (peak), +6 hours and +24 hours (trough) after the start of infusion. Primary outcome was PK/PD target attainment defined as a peak/MIC >8, corresponding with both actual MIC values documented from isolated pathogens, as well as EUCAST susceptibility breakpoints for Enterobacteriaceae and P. aeruginosa; that is, 8 mg/l. Non-compartmental analysis was used to calculate PK parameters.

**Results** During a study duration of 20 months, 50 patients were enrolled in each dosing regimen resulting in 100 peak concentrations, 92 and 88 +6 hours and +24 hours concentrations respectively. Target attainment using local MIC values (median 2 mg/l, documented in 56 isolated Gram-negative pathogens) was achieved in 95% in both groups (P = 0.98). Using EUCAST susceptibility breakpoints, the target was attained in 76% versus 40% in the 25 versus 15 mg/kg group, respectively (P < 0.0001). Single-dose PK parameters are displayed in Table 1 and compared with the ones reported in the ICU [1].

**Table 1 (abstract P118)**

<table>
<thead>
<tr>
<th>PK parameter</th>
<th>15 mg/kg ED</th>
<th>25 mg/kg ED</th>
<th>25 mg/kg ICU</th>
</tr>
</thead>
<tbody>
<tr>
<td>Peak (mg/l)</td>
<td>58 (47 to 70)</td>
<td>91 (72 to 105)</td>
<td>73 (62 to 90)</td>
</tr>
<tr>
<td>Trough (mg/l)</td>
<td>6 (3 to 12)</td>
<td>5 (3 to 15)</td>
<td>7 (2 to 15)</td>
</tr>
<tr>
<td>Vd (l/kg)</td>
<td>0.1 (0.3 to 0.5)</td>
<td>0.4 (0.2 to 0.6)</td>
<td>0.4 (0.3 to 0.5)</td>
</tr>
<tr>
<td>Cl (ml/minute)</td>
<td>1.6 (1 to 2.5)</td>
<td>2.2 (1.4 to 3)</td>
<td>1.9 (1.3 to 3.5)</td>
</tr>
</tbody>
</table>

**Conclusion** The EUCAST-based PK/PD target was only attained in 76% of patients treated with 25 mg/kg. However, in contrast to ICU patients, the majority of ED patients are treated for community-acquired infections, so MIC values are significantly lower than the EUCAST susceptibility breakpoints, warranting PK/PD target attainment in both 25 and 15 mg/kg dosing regimens when local epidemiology is taken into account.

Introduction Amikacin Inhale is an integrated drug–device combina
tion in development by Bayer HealthCare through a collaboration with Nektar Therapeutics, to improve clinical outcome in intubated and mechanically ventilated patients with Gram-negative pneumonia. It is available in two configurations: on-vent for intubated patients and hand-held for extubated patients to complete aerosolized antibiotic therapy. Amikacin Inhale is a smart system that consists of the pulmonary drug delivery system with a vibrating mesh nebulizer and the specially formulated Amikacin Inhalation Solution (400 mg every 12 hours for 10 days). The objectives of this study were to evaluate the performance of the Amikacin Inhale hand-held configuration with supplemental O₂ concentration supplied at different flow rates and in different orientations. We hypothesize that the delivered dose of amikacin will not significantly change with increased O₂ flow rate or varying orientation.

Methods In the hand-held configuration of Amikacin Inhale, amikacin is aerosolized into a holding chamber. Amikacin aerosol is inhaled with ambient air entering the bottom of the chamber through the inhalation valve. Supplemental O₂ may be supplied through the O₂ port and mixes with ambient air entering through the inhalation valve. O₂ concentration and delivered dose at the mouthpiece exit were characterized in vitro at various O₂ flow rates (2 to 10 l/minute). O₂ concentrations were measured every minute until the end of dosing. A ventilator was connected to the set up to simulate patient breathing. The delivered dose was measured at the exit of the mouthpiece. Drug distribution within the test setup compartments was analyzed using HPLC. The in vitro delivered amikacin dose was also measured at nebulizer orientations of 0° and 45° (n = 3 per orientation) using a simulated breathing profile with no supplemental O₂.

Results The mean O₂ concentration ranged from 36 to 70% over 2 to 10 l/minute and was ≥40% at ≥3 l/minute. O₂ concentrations were measured every minute until the end of dosing. A ventilator was connected to the set up to simulate patient breathing. The delivered dose was measured at the exit of the mouthpiece. Drug distribution within the test setup compartments was analyzed using HPLC. The in vitro delivered amikacin dose was also measured at nebulizer orientations of 0° and 45° (n = 3 per orientation) using a simulated breathing profile with no supplemental O₂.

Conclusion Amikacin Inhale was shown in vitro to be suitable for extubated patients who require supplemental O₂. The delivered dose was independent of supplemental O₂ and device orientation.

P121 Early preventive administration of inhaled tobramycin in severe polyantrauma

A Kuzovlev, A Shabanov, T Chemenkaya, V Moroz, A Goloubev
V A Negovsky Research Institute of General Reanimatology; Moscow, Russia; NV Skif этаf Skaff aty Research Institute; Moscow, Russia

Introduction Nosocomial pneumonia (NP) occurs in 30 to 50% of multiple trauma patients. It is mostly caused by multiresistant Gram-negative bacteria. Use of inhaled antibiotics as adjuncts to systemic antibiotics presents a great outlook for the prevention of NP in multiple trauma patients. The aim of the study was to evaluate the efficacy of early administration of inhaled tobramycin (IT) as an adjunct to systemic antibiotics for the prevention of NP in polyantrauma.

Methods Fifty-four ICU mechanically ventilated patients with multiple trauma (ISS >30; car accident 55.6%; fall 29.6%; train accident 11.1%; domestic 3.7%) were enrolled in the single-center randomized trial. Groups were comparable in ISS, age, sex, type of trauma, and blood loss. Patients were randomized into two groups: Group 1 (n = 27), addition of IT to systemic antibiotics (ciprofloxacin 800 mg/day; metronidazol 1,500 mg/day); Group 2 (n = 27), only systemic antibiotics (same regimen). Inhaled tobramycin (300 mg twice daily via nebulizer) and systemic antibiotics were administered within the first 24 hours after ICU admission. After obtaining the results of bronchoalveolar lavage microbiology, the antibiotic regimen was switched according to the sensitivity. The primary outcome measure was new onset of NP and duration of ICU stay. Microbiological, X-ray, CPIS, signs of sepsis and oxygenation index were used as objective indicators of the clinical progress. The secondary outcome measure was 30-day mortality. Diagnosis of NP was made according to the standard clinical and CPIS criteria. The data were statistically analyzed by SPSS 11.5 (M, o–Neman–Keuls test; chi-square-test P <0.05).

Results Preventive administration of IT as an adjunct to systemic antibiotics was associated with a lower incidence of NP in group 1 (group 1 33.3%, group 2 66.7%, χ² = 6,000; P = 0.014) and a shorter duration of ICU stay (group 1 8.0 ± 4.6 days vs. 17.1 ± 18.4 days, P = 0.03). The mortality did not differ between groups: 11.1% in group 1 and 22.2% in group 2 (P ≥0.99). On day 3 Acinetobacter spp. (30.5%), K. pneumoniae (22.0%), B. cepacia (13.2%) and P. aeruginosa (34.3%) were detected in BAL, there were no differences between groups. In group 1 CPIS remained stable and APACHE II decreased. CPIS and APACHE II were lower in group 1 on day 5 (P = 0.0004).

Conclusion Early administration of IT as an adjunct to systemic antibiotics is effective in prevention of NP in multiple trauma patients: it promotes decrease of NP incidence and decrease of ICU stay.

P122 Intrathelial administration of colistin, vancomycin and amikacin for central nervous system infections in ICU neurosurgical patients

P Alexandr, S Georgiou, V Chantziara, E Chinou, V Karagiannisa, G Michaloudis
Saint Savvas Oncology Hospital, Athens, Greece

Introduction Central nervous system (CNS) infections in ICU patients after neurosurgery are a difficult and life-threatening complication demanding immediate action. In many cases intravenous (i.v.) administration of antibiotics is not sufficient; thus, intrathecal (i.t.) administration is required.

Methods From January 2013 to November 2014 all cases with CNS infections were recorded. Inclusion criteria were the presence of fever ≥38.5°C, increased inflammatory markers, compatible lumbar puncture (LP) findings (increased number of polymorphonuclear leukocytes, increased protein and low glucose compared with serum levels) and no evidence of other site of infection. All subjects were receiving appropriate i.v. antibiotic treatment based on cultures. Intrathecal administration of 300,000 iu colistin, 25 mg vancomycin and 25 mg amikacin was performed taking under consideration that neurosurgical patients in the ICU have CNS infection attributed to Gram-negative bacteria or/to Staphylococcus species.

Results Overall, nine cases with CNS infection were recorded aged from 22 to 74, all males. LP was performed between the second and 17th day (average 8.3 days) and the CSF analysis showed 40 to 6,000 cells – mainly PMNs, protein 161 mg% to 287 mg% and glucose from 3 to 58 mg/dl. They were all colonized with Acinetobacter baumannii sensitive only to colistin. CSF cultures were negative for all patients besides one, who grew A. baumannii. Of those, seven (77%) were receiving i.v. colistin, eight (88%) carbapenems, and eight (88%) glycopeptides, all in combination with other antibiotics. Median i.t. administration time was 9.1 days. All patients responded to i.v. and i.t. antibiotics but there was one case in which fever relapsed and increased number of cells in subsequent LP was observed which was attributed to colistin, which was withdrawn. All these patients survived, and were discharged to the ward.

Conclusion Patients treated with the abovementioned regime showed clinical and biochemical improvement. The above drug combination turned out to be successful in neurosurgical ICU patients with CNS infection.

Efficacy and safety of heparin in patients with sepsis: a systematic review and meta-analysis

R. Zarychanski, AM Abou-Setta, S Kanji, AF Turgeon, A Kumar, DS Houston, E Rimmer, BL Houston, L McIntyre, AE Fox-Robichaud, PC Hebert, DJ Cook, DA Ferguson

University of Manitoba, Winnipeg, MB, Canada; Ottawa Hospital Research Institute, Ottawa, ON, Canada; Université Laval, Québec City, QC, Canada; University of Toronto, ON, Canada; McMaster University, Hamilton, ON, Canada; Centre Hospitalier Universitaire de l’Université de Montréal (CHUM) – Hôpital Notre-Dame, Montreal, QC, Canada

Introduction Septic shock is characterized by systemic inflammation coupled with upregulation of coagulation. Heparin is an inexpensive and widely available anticoagulant with anti-inflammatory properties. The objectives of our study were to evaluate the efficacy and safety of heparin in patients with sepsis, septic shock or disseminated intravascular coagulation (DIC) associated with infection.

Methods We included randomized controlled trials from MEDLINE, EMBASE, CENTRAL, Global Health, Scopus, Web of Science, the International Clinical Trials Registry Platform (inception to April 2014), conference proceedings, and reference lists of relevant articles. Two reviewers independently identified and extracted trial-level data from randomized trials investigating unfractionated or low molecular weight heparin administered to patients with sepsis, severe sepsis, septic shock or DIC associated with infection. Internal validity was assessed in duplicate using the Risk of Bias tool. Our primary outcome was mortality. Safety outcomes included hemorrhage, transfusion and thrombocytopenia.

Results We included nine trials enrolling 2,637 patients. Eight trials were of unclear risk of bias and one was classified as having low risk of bias. In trials comparing heparin with placebo or usual care, the risk ratio for death associated with heparin was 0.88 (95% CI = 0.77 to 1.00, P = 0.0, 2477 patients, six trials). In trials comparing heparin with other anticoagulants, the risk ratio for death was 1.30 (95% CI = 0.78 to 2.18, P = 0%, 160 patients, three trials). In trials comparing heparin with placebo or usual care, major hemorrhage was not statistically significantly increased (risk ratio 0.79, 95% CI = 0.53 to 1.17, P = 0%, 2392 patients, three trials). In one small trial of heparin compared with other anticoagulants, the risk of major hemorrhage was significantly increased (2.14, 95% CI = 1.07 to 4.30, 48 patients). Important secondary and safety outcomes, including minor bleeding, were sparsely reported.

Conclusion Heparin in patients with sepsis, septic shock, and DIC associated with infection may be associated with decreased mortality; however, the overall impact remains uncertain. Safety outcomes have been under-reported and require further study. Large randomized trials are needed to evaluate the efficacy and safety of heparin in patients with sepsis, severe sepsis, and septic shock.

Use of intravenous immunoglobulin to treat sepsis in a general ICU

Y Drakeford, J Kelly, P Morgan, J Melville, A Holland

Surrey and Sussex Healthcare NHS Trust, Redhill, UK

Introduction Sepsis is a major cause of admission to the ICU, and a leading cause of death for ICU patients. Intravenous immunoglobulin (IVIg) is gaining increased in the treatment of some patients with sepsis, although the evidence for this remains controversial. The use of IVIg is regulated due to its high cost, and prescription guidelines have been revised by the NHS, coordinated by the National Demand Management Programme for Immunoglobulin.

Methods We conducted a retrospective audit of pharmacy records of IVIg prescriptions issued to ICU patients with severe sepsis and septic shock from 2009 to 2014 against national prescription guidelines. Microbiology results were examined to support prescriptions, and admission APACHE II scores and unit outcomes were examined.

Results From 2009 to 2014, 644 patients were admitted to the ICU with severe sepsis and septic shock, with a mortality rate of 41%. Seventeen patients received IVIg. Of these, eight patients met the national guidelines for prescription, with a mortality rate of 25%. Nine patients did not meet the national guidelines for prescription, with a mortality rate of 44%. The difference in mortality rates between the two groups did not reach statistical significance (P = 0.6). There was no significant difference in APACHE II scores between the two groups. There was also no difference in mortality between those receiving IVIg and those who did not. We also found no difference in those receiving single or double doses of IVIg.

Conclusion The use of IVIg does not appear to affect mortality in sepsis. There was also no statistical benefit or harm demonstrated by using IVIg. This also holds true whether IVIg is given either according to the guidelines or not; however, stricter adherence to the guidelines does have financial implications.

Adjust prenisone therapy for patients with community-acquired pneumonia: a randomized, placebo-controlled multicenter trial

1 University-Hospital Basel, Switzerland; 2 Medical University Clinic, Kantons spitale Aarau, Switzerland; 3Kantons spitale Basel/Liestal, Liestal, Switzerland; 4Kantons spitale Basel/Bruderholz, Bruderholz, Switzerland; 5Burgspital, Solothurn, Switzerland; 6Inselspital, Bern University Hospital, Bern, Switzerland; 7Hôpital du Jura, Site de Delémont, Delémont, Switzerland; 8Voilier SA, Basel, Switzerland

Introduction Clinical trials yielded conflicting data about the benefit of adding systemic corticosteroids for community-acquired pneumonia (CAP). We evaluated whether short-term corticosteroid treatment reduces time to clinical stability in patients hospitalized for CAP.

Methods This randomized, placebo-controlled multicenter trial compared prednisone 50 mg for 7 days with placebo in patients hospitalized with CAP. The primary endpoint was time to clinical stability. Results Overall, 802 patients were randomized in seven Swiss hospitals from December 2009 to May 2014. Time to clinical stability was shorter in the prednisone group compared with placebo (3.0 vs. 4.4 days, HR = 1.33, 95% CI = 1.15 to 1.50, P < 0.001). The prednisone group as compared with the placebo group had a shorter time to hospital discharge (6 vs. 7 days (HR = 1.19, 1.04 to 1.38, P = 0.012) and a shorter duration of intravenous antibiotic treatment (4 vs. 5 days (difference, –0.89 days, –0.20 to –1.57 days), P = 0.011). All-cause mortality, ICU stay, recurrent pneumonia and rehospitalization rate were similar in both groups. Incidence of pneumonia-associated complications until day 30 tended to be lower in the prednisone group (2.8% vs. 5.6%, OR = 0.49, 0.23 to 1.02, P = 0.06). The prednisone group had a higher rate of in-hospital hyperglycemia needing insulin treatment (19.4% vs. 10.9%, OR = 1.96, 1.31 to 2.93, P = 0.001). Other adverse events compatible with corticosteroid use were rare and similar in both groups.

Conclusion Prednisone treatment for 7 days in hospitalized patients with CAP shortens time to clinical stability, time to hospital discharge and duration of intravenous antibiotic treatment without an increase in complications.

Pharmacokinetics, safety and tolerability of human recombinant alkaline phosphatase in healthy volunteers

E Peters, J Arendts, P Tiessen, A Van Elsas, P Maseneeuw, P Pickkers

1 Radboudum, Nijmegen, the Netherlands; 2 AM-Pharma, Brunik, the Netherlands; 3PRA Health Sciences, Zuidlaren, the Netherlands

Introduction Clinical trials showed renal protective effects of bovine intestinal alkaline phosphatase in critically ill patients with
sepsis-associated acute kidney injury (AKI) [1,2]. Recently, human recombinant AP (recAP) was developed as a pharmacological attractive replacement. We conducted a phase I clinical trial to evaluate tolerability, safety and pharmacokinetics of recAP in healthy volunteers.

Methods In a randomized, double-blind, placebo-controlled phase I trial, healthy volunteers received via a 1-hour i.v. infusion a single dose of recAP (200, 500, 1,000 or 2,000 U/kg; n = 33) or multiple doses of recAP (500 or 1,000 U/kg; n = 18) on three consecutive days (n = 18). Serum recAP concentrations, AP activity levels and anti-drug antibodies were measured, and safety parameters were monitored.

Results RecAP administration resulted in a terminal elimination half-life and plasma clearance of 49 to 58 hours and 2.8 to 3.4 l/hour after single ascending doses, respectively, and 63 to 66 hours and 3.1 to 3.8 l/hour after multiple ascending doses. Peak recAP concentrations and AP activity levels were reached at the end of the 1-hour infusion and showed a rapid decline with about 10% of the maximum concentration remaining at 4 hours and less than 5% at 24 hours post start. Although the maximal concentration and total systemic exposure of recAP and AP activity increased slightly more than dose proportionally this is of no significance in the estimated therapeutic dose range. RecAP treatment was generally well tolerated and anti-drug antibodies could not be detected in serum.

Conclusion AP is characterized by a long serum terminal half-life, by stable serum AP levels and did not exert any safety concerns when administered to healthy volunteers. These results pave the way to investigate the potential of recAP as a new treatment option for sepsis-associated AKI in a phase II clinical trial, which will start at the end of 2014 [Clinical Trial Register:NCT02182440].

P127 Rat polymyxin B hemoperfusion model: preventive effect on renal tubular cell death in a rat cecal ligation and puncture model

T Masuda1, C Mitaka2, M Khin Hnin Si2, K Kido2, Y Qi2, T Uchida2, S Abe2, T Miyasho3, M Tomita4

1Tokyo Medical and Dental University, Tokyo, Japan; 2Tokyo Medical and Dental University Graduate School, Tokyo, Japan; 3Rakuno Gakken University, Hokkaido, Japan; 4Tokyo Medical and Dental University Hospital of Medicine, Tokyo, Japan

Introduction Direct hemoperfusion with a polymyxin B immobilized column (PMX-DHP) adsorbs endotoxin and has been used for the treatment of septic shock [1]. However, the mechanisms of action behind PMX-DHP are not fully understood. Therefore, the purpose of this study was to elucidate mechanisms of action behind PMX-DHP in a rat model of cecal ligation and puncture.

Methods Sprague–Dawley rats were anesthetized and were mechanical ventilated after tracheostomy. The right internal carotid artery was cannulated with a catheter for continuous measurement of the arterial pressure and heart rate. The right femoral vein was cannulated with a catheter for infusion of saline (10 ml/kg/hour) during the study period. The rats were randomized into three experimental groups: cecal ligation and puncture (CLP) + dummy column (Dummy-DHP) group (n = 10), CLP + PMX-DHP group (n = 10), and sham group (n = 4). Four hours after CLP, Dummy-DHP or PMX-DHP was performed for 1 hour. Blood was drawn from the right internal carotid artery, perfused through PMX column or dummy column, and returned to the right femoral vein. The heart rate, mean arterial pressure, arterial blood gases, and plasma concentrations of creatinine, lactate, potassium, and cytokines (IL-6 and IL-10) were measured at baseline and at 4, 5, and 8 hours after CLP. At the completion of the experiment, the rats were killed by overdose of pentobarbital. The kidney, liver, and lung were harvested, and histopathologic examinations of these organs were performed.

Results Hypotension and metabolic acidosis occurred in the CLP + Dummy-DHP group, whereas hemodynamics and acid–base balance were better maintained in the CLP + PMX-DHP group. Plasma concentrations of lactate, creatinine, potassium, and cytokines were significantly higher in the CLP + Dummy-DHP group than in the CLP + PMX-DHP group at 8 hours. Renal tubular cell death was observed in the CLP + Dummy-DHP group, but not in the CLP + PMX-DHP group.

Conclusion PMX-DHP improved hemodynamics, acid–base balance, and creatinine levels through reducing cytokines and renal tubular cell death in a rat model of cecal ligation and puncture. These findings suggest the preventive role of PMX-DHP in the development of sepsis-related acute kidney injury.

P128 White blood cell counts have an impact on septic patient outcome followed by polymyxin-B immobilized fiber with direct hemoperfusion

H Tanaka, T Ikeda, S Ono, S Suda, T Ueno
Tokyo Medical University, Hachioji Medical Center, Hachioji, Japan

Introduction The mortality rate of severe sepsis and septic shock is varied and high (25 to 70%). In our institute, the indication for polymyxin-B immobilized fiber with direct hemoperfusion (PMX-DHP) has been that circulatory failure (systolic blood pressure <90 mmHg or required catecholamines and high lactacidemia) continued despite following early goal-directed therapy by the Surviving Sepsis Campaign guidelines 2012.

Methods This study included 80 patients with severe sepsis or septic shock due to abdominal infection retrospectively. These subjects were divided into two groups: those with WBC counts <4,000 (L-group: 64 patients) and those with WBC counts >12,000 (H-group: 16 patients).

Results The mortality rate of 28 days in the L-group was 32.8%, and was 18.8% in the H-group. Mean arterial pressure increased significantly (P <0.01) in the H-group compared with the L-group. WBC counts in the L-group increased and in the H-group decreased (P <0.01) during PMX-DHP treatment. Platelet counts in both groups decreased significantly (P <0.01). There was no significant difference between before and after PMX-DHP in IL-6 levels. On the other hand, IL-1ra decreased significantly before and after PMX-DHP. Also, IL-6 and IL-1ra in the L-group were significantly higher than those in the H-group at the start of PMX-DHP. Statistical analysis was performed using the chi-squared test for background factors, with Wilcoxon’s rank-sum test for comparison within a group, and Mann–Whitney’s U test for comparison between groups. The significance level was set at P <0.05.

Conclusion The mortality rate of the L-group tended to be higher than that of the H-group. Inflammatory and anti-inflammatory cytokines in the L-group were higher than those of the H-group. These results indicate that leukopenia (WBC <4,000) in severe sepsis patients leads to more severe outcome and hypercytokinemia than leukocytosis (WBC >12,000) in severe sepsis patients.
exchange therapy may improve thrombotic microangiopathy [1]. The purpose of this observational cohort study is to describe whether there is an association between use of plasma exchange therapy and outcome in the Turkish TAMOF network.

Methods We performed a retrospective cohort analysis in patients with TAMOF at three different pediatric ICUs comparing those who received plasma exchange (+) plus standard therapies with those who did not receive plasma exchange (−) and only received standard therapies.

Results Among the 42 TAMOF patients enrolled, all had a primary or secondary sepsis diagnosis. Fifteen received plasma exchange therapy (PE(+)) group and 27 received standard medical treatment without plasma exchange (PE(−) group). The mean age was 17.69 months (8.24 to 54.22) in the PE(+) group, and 13.46 months (6.47 to 20.55) in the PE(−) group. Age (P = 0.232), gender (P = 0.206), thrombocyte count (P = 0.09), OFI score (P = 0.111) and Pelod score (P = 0.177) on admission were not statistically different between groups. The overall 28-day mortality was higher in the PE(−) group 70.37% compared with 26.67% in the PE(+) group (univariate P = 0.006; multivariate controlling for Pelod, OFI, PRISM scores and neurological failure P = 0.048). Length of stay was increased in the PE(+) group (P = 0.004).

Conclusion The positive association found between use of plasma exchange therapy and improved survival supports the potential of this therapy in Turkish children with TAMOF. The positive, although less so, associated treatment effect observed after controlling for illness severity provides further rationale for performing a randomized controlled trial in the pediatric Turkish TAMOF network. Sample size calculations call for a 100-patient trial with a pre hoc interim analysis after enrollment of 50 TAMOF patients.

Clinical experience of using a novel extracorporeal cytokine adsorption column for treatment of septic shock with multiorgan failure
P Sathe, P Sakhavalkar, S Kumar, S Choudhary
Ruby Hall Clinic, Pune, India

Introduction Severe sepsis and multiorgan failure (MOF) are major causes of death in the ICU. The extracorporeal cytokine adsorption column (ECAC; CytoSorb®, CytoSorbents Corporation, USA), a critical care focused therapeutic device, results in rapid in vitro and in vivo elimination of several key cytokines and prevents organ failure. Use of ECAC in patients with sepsis is a new area of research with insufficient data to promote large prospective RCTs. Studies published to date have shown promising results. We report our clinical experience with ECAC for severe sepsis/septic shock/MOF patients.

Methods A retrospective evaluation of ECAC in patients admitted to a tertiary ICU from November 13 to October 14 to analyze: clinical safety; outcome in the Turkish TAMOF network.

Results Nineteen ICU patients (14 men, five women; 24 to 72 years; average ICU stay 10 days; average ventilator days 9) with APACHE II >17 (except one with dengue shock syndrome), SOFA score ≥11 (n = 16) and the majority having infection largely in the lung (n = 8; alone or with UTI and blood infection) followed by the abdomen (n = 4), UTI (n = 3) and others (n = 4) were given ECAC (total ECAC = 31). Predicted mortality (PM) was >40% in 16, >30% in two and <30% in two (two infections) patients. Duration of therapy was 6 hours (no. of ECAC = 18) and 8 hours (n = 4; no. of ECAC = 5) for the majority of patients. Overall, four patients (two with tropical infections and two with PM >40%) survived; three of them had were ECAC early (<24 hours of admission). The majority of patients (n = 11) who died could be given ECAC only once. Of patients who died, seven were given ECAC late (>24 hours), APACHE scores before and after ECAC therapy were available for eight patients who died; APACHE score decreased >5 points in five patients after single application of ECAC.

Conclusion ECAC can be used as adjuvant therapy in treatment of severe sepsis/septic shock/MOF. Our patients had high PM and four could be saved with use of ECAC. We could expect a better outcome if ECAC was used early (<24 hours) during treatment. However, future well-designed studies are needed to clarify the role of ECAC in patients with MOF/septic shock.

P131
Effectiveness of polymyxin B immobilized fiber hemoperfusion in patients with septic shock due to Gram-negative bacillus infection: the PMXHP study
N Saito, K Sugiyama, T Ohnuma, T Kanemura, N Nasu, Y Yoshidomi, H Adachi, H Koami, Y Tsujiito, A Tsuchiki, Y Wagaatsu, T Miyumi
1 Chiba Hokuso Hospital, Nippon Medical School, Chiba, Japan; 2 Tokyo Metropolitan Bokuto Hospital, Tokyo, Japan; 3 Saitama Medical Center, Jichi Medical University, Saitama, Japan; 4 National Hospital Organization Disaster Medical Center, Tokyo, Japan; 5 Urasoe General Hospital, Okinawa, Japan; 6 Saga University Hospital, Saga, Japan; 7 Saga University Hospital, Saga, Japan; 8 Yamagata Prefectural Central Hospital, Yamagata, Japan; 9 Tsukuba Medical Center Hospital, Ibaraki, Japan; 10 University of Tsukuba, Ibaraki, Japan; 11 University of Occupational and Environmental Health, Fukuoka, Japan

Introduction Mortality from septic shock in the ICU remains high, ranging from 30 to 50%. In particular, Gram-negative bacilli (GNB) account for 40% of the causative bacteria of severe sepsis, which progresses to multiorgan failure due to significant inflammation. Hemoperfusion with polymyxin B-immobilized fiber (PMX) adsorbs endotoxin and can reduce the inflammatory cascade of sepsis due to GNB. However, the clinical efficacy of this treatment has not been demonstrated. We aimed to verify the efficacy of endotoxin adsorption therapy by using PMX.

Methods We retrospectively evaluated 387 patients who received a broad-spectrum antimicrobial treatment for septic shock due to GNB between January 2009 and December 2012 in the ICU of 10 Japanese tertiary hospitals. After alignment of the treatment time phase for each patient, we divided the patients into two groups according to whether PMX treatment was performed within 24 hours after ICU admission (PMX group: n = 129 and non-PMX group: n = 258). The primary endpoint was 28-day mortality.

Results The mean (SD) age and SOFA scores on ICU admission were 72.5 (12.5) years and 10.0 (3.4), respectively. The infection site was intra-abdominal (47.0%), pulmonary (17.6%), and urinary tract (27.8%). Two-thirds of all patients had bacteremia due to GNB. No difference in 28-day mortality was observed between the two groups (PMX: 33.9% vs. non-PMX: 33.1%, P = 0.87). In the Cox regression analysis adjusted for age, sex, and facilities, the PMX treatment (hazard ratio = 0.87; 95% confidence interval, 0.53 to 1.43) did not improve the outcome.

Conclusion No difference in mortality rate was observed after adjustment for the endotoxin adsorption therapy with PMX in the patients with septic shock due to GNB.

P132
Impact of evolving cardiac catheterisation services on admissions to a regional ICU
EA Gorman, D Trainor
Royal Victoria Hospital, Belfast, UK

Introduction National UK audit data demonstrate cardiac catheterisation services, including percutaneous coronary intervention and noncoronary interventions, are increasing [1-3]. National mortality rates post cardiac catheterisation are also increasing, reflecting an increasing proportion of sicker patients undergoing interventional procedures [3]. National audit procedures do not evaluate patients admitted to intensive care post cardiac catheterisation. We aimed to
evaluate the impact of an evolving regional cardiac catheterisation service on a regional intensive care unit (RICU) serving a population of 1.8 million.

Methods A retrospective review was carried out. Patients admitted from the regional cardiac catheterisation laboratory to the regional ICU, between September 2009 and September 2014, were identified using validated RICU admission records. Clinical data were extracted from computerised patient records.

Results A total of 170 patients were identified (representing 2.9% of critical care admissions during this time). Baseline characteristics: 71.7% male, median age 66 (IQR 55 to 74), median APACHE score 18 (IQR 15 to 23). Seventy-one patients (41.7%) had an APACHE score >20. Fifteen patients (8.8%) were aged >80 years. Admissions increased yearly – 20 in 2010, 26 in 2011, 35 in 2012, 47 in 2013, 37 at the end of the third quarter of 2014 (projected 59 admissions by year end 2014). Median length of stay was 3.5 days (IQR 1.9 to 7.2). Average length of stay reduced yearly (9.14 days in 2010 to 5.01 days in 2014), ICU bed-days per year remained static over the 5-year period. Critical care and hospital mortality rates were 33% and 39% respectively. There was a trend towards increasing mortality yearly, and with increasing age and APACHE score.

Conclusion An evolving cardiac catheterisation service is having a significant impact on intensive care services within a regional centre. Increasing mortality trends in this critical care population reflects post-cardiac catheterisation mortality trends nationally. We suggest intensive care admissions post cardiac catheterisation should be included in the national audit, to allow forward planning of intensive care services and to promote quality improvement within this population.

Impact of the introduction of e-learning prior to a basic transthoracic echo course
P Madhivathanan1, S Jain1, D Walker1
1Barts Health NHS Trust, London, UK; 2Homerton University Hospitals NHS Foundation Trust, London, UK; 3University College London Hospitals NHS Foundation Trust, London, UK

Introduction Focused Intensive Care Echo accreditation is a nationally approved pathway for training and accreditation in basic transthoracic echocardiography (TTE) in the UK. Recently, an e-learning module, the Intensive Care Echo and Basic Lung Ultrasound (ICE-BLU), has been introduced to facilitate TTE learning [1]. Previous work from our group has shown that incorporating simulation-based teaching elements into a basic TTE course improves candidates’ satisfaction [2]. We assessed the impact of introducing the ICE-BLU e-learning programme prior to our simulation-based basic TTE course.

Methods Prior to the August 2014 course, all candidates were required to complete the ICE-BLU e-learning module. On the morning of the course, the candidates completed a questionnaire to assess the impact of the e-learning module. The survey included questions on the quality of content, user friendliness, whether the content was pitched at the right level and any problems faced whilst accessing the e-learning module. We also analysed candidates’ feedback from our January and August 2014 courses (Figure 1).

Results The response rate of the survey was 100%. Eighty per cent of candidates completed the e-learning module. The e-learning module was rated high by most candidates (80%). However, nearly one-half of the candidates faced problems accessing the module, online. Analysis of candidates’ feedback (from the January and August 2014 courses) revealed that candidates’ overall impression was better with the introduction of e-learning prior to the course.

Conclusion Our survey has shown that the e-learning initiative was welcome by the candidates. We conclude that introduction of e-learning prior to a simulation-based basic TTE course enhances candidates’ satisfaction and feedback.

Diagnostic concordance of emergency doctor-performed bedside ultrasonography versus specialist-performed echo-Doppler ultrasonography in the diagnosis of deep venous thrombosis of lower limbs
DL Ly-Pen1, JP Penedo Alonso2, MS Sánchez Perez2, FR Roldán Moll2, MZ Zamorano Serrano2, LD Díaz Vidal2, SJ Justo2
1Southend University Hospital, Westcliff-on-Sea, UK; 2Hospital Universitario Ramón y Cajal, Madrid, Spain; 3Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Madrid, Spain

Introduction Deep venous thrombosis (DVT) is an increasing major cause of mortality and morbidity. There is a need for quick, easy, cheap, convenient and reliable diagnostic tools. The objectives were to ascertain the diagnostic concordance of emergency doctor-performed ultrasound (EDUS) of the lower extremities with specialist doctor-performed (radiologist or vascular surgeon) echo-Doppler (SDED), in the diagnosis of DVT, and to identify possible causes of nonconcordance.

Methods A prospective, multicentre study. Adult patients (>18 years old) with clinical suspicion of DVT, with high or moderate risk (on Wells scoring), or low risk with increased D-dimer levels, were eligible for the study. Emergency doctors performed two EDUS in femoral and popliteal areas (these results were blinded). After this, echo-Doppler was performed by specialist doctors. Both procedures were done within 24 hours of each other. The final result was considered nonconcordant if one or both of the EDUS did not match with the SDED. These SDED were used as reference (as standard clinical practice).

Results From September 2013 to September 2014, a total of 328 patients were enrolled. Fifty-one investigators from seven hospitals performed the EDUS. Each patient had the EDUS (femoral and popliteal areas) and SDED (also in femoral and popliteal areas). Of 328 pairs of US studies, 37 were nonconcordant between EDUS and SDED. Two EDUS were incomplete, so the concordance analysis was performed with 326 US studies, with 35 discordant. The percentage of agreement between EDUS and SDED was 89.26%. The kappa index was 0.76 (95% CI = 0.69 to 0.84), and this means a substantial agreement.

Conclusion There is substantial agreement between EDUS and SDED in the diagnosis of DVT, in routine clinical practice. This confirms the results of previous papers. The largest nondiagnostic concordance in thrombus occurs in the early performances of emergency doctors,
especially until the fifth performance. After the sixth one, the incidence of mismatches falls dramatically. It seems advisable to mentor the training programmes with at least five shadowed performances in order to lower the incidence of mistakes.

Cardiac abnormalities in patients with septic shock detected by speckle tracking echocardiography

PY Ng1, WC Sin, AK Wong, WM Chan

1Queen Mary Hospital, Hong Kong; 2Grantham Hospital, Hong Kong

**Introduction** Sepsis-induced myocardial dysfunction is a well-recognized condition and confers worse outcomes in septic patients. However, the diagnostic criteria remain poorly described. Echocardiographic assessment by conventional parameters such as left ventricular ejection fraction (LVEF) is often affected by ongoing changes in preload and afterload conditions. Novel echocardiographic technologies such as speckle tracking imaging have evolved for direct assessment of the myocardial function. In this study, we investigate the measurement of myocardial strain by speckle tracking imaging for the diagnosis of sepsis-induced myocardial dysfunction.

**Methods** This is a prospective, case–control study at a university-affiliated tertiary care adult medical ICU. Consecutive patients admitted with a diagnosis of septic shock meeting the international consensus criteria were included. Patients with other causes of myocardial dysfunction were excluded. They were compared with age-matched, gender-matched, and cardiovascular risk-factor-matched controls, who were admitted to hospital for sepsis but did not develop septic shock. Conventional echocardiographic parameters, as well as speckle tracking imaging of myocardial function, were obtained within 24 hours of diagnosis. Offline analyses of endocardial tracings were performed by two independent operators.

**Results** From January 2014 to December 2014, 32 patients with septic shock (study group) and 20 patients with sepsis but no septic shock (control group) were recruited. The baseline characteristics were similar. Conventional echocardiographic measurements, including LVEF (59.53% vs. 60.67% in the control group, P = 0.450) and fractional shortening (31.98% vs. 32.98%, P = 0.323), did not differ between the two groups. The study group had a greater degree of myocardial dysfunction measured by left ventricular global longitudinal strain (–14.6 vs. –17.6, P = 0.005, with a less negative value implying worse myocardial contractility). The hemodynamic profiles (cardiac index 3.49 l/minute/m² vs. 3.41 l/minute/m², respectively, P = 0.323) did not differ statistically.

**Conclusion** This is a first study in the adult population to show that the use of speckle tracking imaging can diagnose significant sepsis-induced myocardial dysfunction, which was not otherwise detectable by conventional echocardiography.

**P136**

Evaluating the effect of sepsis and septic shock on myocardial functions by echocardiography and serum biomarker level in peripheral veins and coronary sinus

M Soliman1, A Alazab, RE Hossainy, M Nirmalan, H Nagy

1Cairo University, Cairo, Egypt; 2University of Manchester, UK

**Introduction** Sepsis is a leading cause of death in critically ill patients despite the use of modern antibiotics and resuscitation therapies. Biomarkers and cardiovascular changes have an important place in this process. Myocardial depression occurs in 40% of septic patients. Twenty markers (group I) with sepsis or septic shock were included and 10 patients (group II) served as the nonseptic group. Group I morbidity and mortality at day 28 in the ICU were targeted as the endpoint. Laboratory investigations, APACHE IV, SAPS II and SOFA scores were calculated. Biomarkers IL-1α, IL-1β, IL-6, IL-10, TNFα, CRP, NT-proBNP and troponin level were estimated on admission and day 7 in the peripheral vein (PV) and coronary sinus (CS). Transthoracic echocardiography and tissue Doppler imaging was done on admission and on day 7.

**Results** Comparing group I versus group II, the mortality rate was 45%, and there was a statistically significant difference for temperature (P = 0.001), HR (P = 0.001) and WBC count (P = 0.01) on admission. Upon comparing survivors versus nonsurvivors in group I there was a statistical difference in HR on day 7 (P = 0.02), successful vasopressor withdrawal (P = 0.02), P/F ratio (P = 0.02) and ScvO2 on day 7 (P = 0.03). Regarding IL-1α, IL-1β, TNFα and troponin I there was no statistical significant difference between groups I and II but IL-6, IL-10 and CRP showed statistically significant difference on admission PV and CS. Pro-BNP shows statistically significant difference in all CS samples between septic and nonseptic groups. Regarding echo upon comparing the survivors versus nonsurvivors, E’/d/t on day 0 shows a statistically significant difference between both groups. SAPS II and seventh-day SOFA are good predictive scores for mortality in sepsis.

**Conclusion** Diastolic dysfunction was seen in 90% of patients. Fever, HR, and WBC counts are still good early indicators for diagnosis of sepsis. Vasopressor withdrawal on the seventh day was a good predictor for survival. Admission serum IL-6, IL-10 and CRP from PV were better indicators for sepsis than IL-1, pro-BNP and troponin I. Admission TNFα and seventh-day IL-6 levels were highly prognostic for mortality. CS samples proved that NT pro-BNP is a good indicator for sepsis diagnosis and a good predictor for survival. TNFα from CS samples was also a good predictor of mortality. SAPS II and a slower E’/d/t on admission was a good predictor of mortality.

**Reference**

and VTI may be good markers of sepsis severity and mortality in newly admitted patients. In addition, further studies are warranted to assess the role of CI and VTI as therapeutic targets.

**Speckle tracking imaging for evaluation of effects of positive end-expiratory pressure level on right ventricular function**

M Türker, A Pirat, A Camkiran Firat, B Pirat, A Sezgin, G Arslan

Baskent University, Ankara, Turkey

**Introduction**

Positive end-expiratory pressure (PEEP) is commonly used to correct hypoxemia in the ICU. However, PEEP may impair right ventricular functions by increasing its afterload. Speckle tracking imaging (STI) is a new echocardiography strain analysis technique that provides direct assessment of myocardial contractility during systole and diastole. The aim of this study was to evaluate the effects of different PEEP levels on right ventricular functions by using STI in patients undergoing coronary artery bypass grafting surgery.

**Methods**

After ethics committee approval and patients’ written consent, we prospectively analyzed 20 CABG surgery patients. After initiation of mechanical ventilation and before sternotomy, 5, 10, and 20 cmH₂O PEEP were applied in 5-minute intervals consequently. After stabilization at each PEEP level, four-chamber and two-chamber images of the right ventricle were recorded using TEE. The right ventricle diameter, velocity, longitudinal strain, SR, and fractional area change (RVFAC) were calculated and evaluated from the recorded images.

**Results**

The mean age of study patients (85% male) was 59.7 ± 10.5 years. Intraoperative mean, systolic, and diastolic arterial blood pressures and heart rate were similar at the three PEEP levels. Compared with 5 and 10 cmH₂O PEEP, mean RVFAC significantly decreased at 20 cmH₂O PEEP (P < 0.001). Right ventricle velocity reduced with incremental PEEP increases (P < 0.05). Mean SR values decreased at 20 cmH₂O PEEP when compared with 5 cmH₂O PEEP (P = 0.03). Mean right ventricle diameter measurements decreased with incremental PEEP increases; however, this decrease was significantly different between 20 cmH₂O PEEP and other two PEEP levels (P = 0.01). The mean right ventricle strain value significantly decreased at 20 cmH₂O PEEP when compared with other two PEEP levels (P < 0.001 for both).

**Conclusion**

Compared with 5 and 10 cmH₂O PEEP levels, right ventricle functions in terms of strain, SR, right ventricle diameter, and RVFAC were significantly impaired at 20 cmH₂O PEEP level.

**PEEP at which LS disappeared or reappeared were compared using the Wilcoxon signed-rank test to assess the influences of anatomical side and PEEP increase or decrease. The values of PEEP at disappearance of LS for the right lung were not statistically significantly different from the left lung (P = 0.844 for increases, P = 0.938 for decreases). The values of PEEP at which LS disappeared obtained during increases were not statistically significantly different from values obtained during decreases (P = 1.000 for left lung, P = 0.875 for right lung: Figure 1). From data pooled from both sides and protocols, the median value of PEEP at which LS disappeared as a false positive sign of pneumothorax was 25 cmH₂O (interquartile range = 20 to 30 cmH₂O). At PEEP = 10 cmH₂O, no patient showed absence of LS, whereas at PEEP = 35 cmH₂O, all patients showed absence of LS (Figure 2).

**Conclusion**

According to this study, higher PEEP levels correlate with disappearance of LS without pneumothorax. Absence of LS in patients with high PEEP should be interpreted with caution and other signs of pneumothorax should be sought before therapeutic interventions are attempted.

**Lung ultrasound in quantifying lung water in septic shock patients**

L De Geer, A Oscarsson, M Gustafsson

Linkoping University Hospital, Linkoping, Sweden

**Introduction**

Quantification of lung ultrasound (LUS) artifacts (B-lines) is used to assess pulmonary congestion in emergency medicine and cardiology [1,2]. We investigated B-lines in relation to extravascular lung-water index (EVLWI) from invasive transpulmonary thermodilution in septic shock patients. Our aim was to evaluate the role of LUS in an intensive care setting.

**Methods**

Twenty-one patients admitted with septic shock to a general ICU underwent LUS of eight zones, four per hemithorax, within 24 hours after ICU admission. EVLWI was calculated simultaneously by transpulmonary thermodilution using a pulse-contour continuous cardiac output system, and NT-proBNP and clinical data were collected. Two physicians blinded to other data independently quantified the number of B-lines. Spearman’s rho was used to test the correlation of B-lines to EVLWI and clinical data, and linear regression and Bland–Altman analysis were used to assess the agreement between B-lines and EVLWI. Interobserver variability was tested using Bland–Altman analysis and intraclass correlation coefficient (ICC).

**Results**

Fourteen patients (67%) were male, the median age was 62 years (IQR 55 to 68) and eight (38%) patients had cardiac comorbidities. In median, SAPS 3 was 64 (IQR 60 to 74), ICU length of stay was 3 days (IQR 2 to 8) and seven patients (33%) died within 30 days of ICU admission. All patients were mechanically ventilated and treated according to
P141

Variations in near-infrared spectroscopy-derived oxygen downslope during a vascular occlusion test in critically ill patients: relationship with outcome

A Donati, E Damiani, A Canesi, V Monaldi, E Montesi, P Pelaia
Università Politecnica delle Marche, Ancona, Italy

Introduction

Near-infrared spectroscopy (NIRS) with a vascular occlusion test (VOT) can be used to extrapolate information regarding the tissue oxygen extraction rate. We explored the meaning of variations in tissue oxygen saturation downslope ($\Delta{}S\text{To}_2$) during a VOT in critically ill patients.

Methods

In this prospective observational study, NIRS (thenar eminence) was applied every day in 93 patients admitted to the ICU. A VOT was performed using a 40% $\Delta{}S\text{To}_2$ target. The slope of the desaturation curve was assessed separately for the first part ($\Delta{}S\text{To}_2$ Down1) and the last part ($\Delta{}S\text{To}_2$ Down2) of the curve and the difference between Down2 – Down1 was calculated.

Results

No significant differences were seen in $\Delta{}S\text{To}_2$ Down1 or Down2 between ICU survivors ($n = 76$) and ICU nonsurvivors ($n = 17$) over the first 10 days in the ICU, while Down2 – Down1 was higher in ICU nonsurvivors (Figure 1). Patients in the upper quartile of mean Down2 – Down1 showed the highest 90-day mortality ($P = 0.014$).

Conclusion

ICU nonsurvivors tended to show a flattening in the last part of the desaturation curve during a VOT, suggesting a reduced tissue oxygen extraction. This may depend on microvascular dysfunction and/or cellular hypometabolic status.

Figure 1 (abstract P141).

Figure 1 (abstract P142).

Conclusion

Hyperoxia induces an early decrease in microvascular perfusion, which appears to go back to normality at return to normoxia.

P143

Near-infrared spectroscopy for assessing the tissue oxygen extraction rate during sepsis: relationship with outcome

A Donati, E Damiani, C Scorcella, S Tondi, S Ciucani, P Pelaia
Università Politecnica delle Marche, Ancona, Italy

Introduction

Microcirculatory dysfunction impairs tissue oxygenation during sepsis. We applied near-infrared spectroscopy (NIRS) to evaluate the tissue oxygen extraction rate in sepsis and its relationship with outcome.

Methods

A prospective observational study; 14 septic patients underwent NIRS monitoring (thenar eminence) with a vascular occlusion test (using a 40% $\Delta{}S\text{To}_2$ target) at admission to the ICU.
Healthy volunteers \((n = 27)\) were studied as controls. The slope of the desaturation curve was assessed separately for the first \((\text{StO}_2\text{ Down1})\) and the last part \((\text{StO}_2\text{ Down2})\) of the curve and the difference between, \text{Down2} – \text{Down1}, was calculated.

**Results** \(\text{StO}_2\text{ Down1}\) was lower in healthy volunteers as compared with septic patients \((P < 0.05)\); no difference was seen between ICU survivors \((n = 7)\) and nonsurvivors \((n = 7)\). \(\text{StO}_2\text{ Down2}\) was similar between healthy volunteers and ICU survivors, while it was higher in nonsurvivors \((P < 0.01\) vs. healthy). ICU nonsurvivors showed higher \text{Down2} – \text{Down1} as compared with ICU survivors \((P < 0.01\), Figure 1). 

**Conclusion** Tissue oxygen extraction was reduced in septic patients. Nonsurvivors showed a flattening in the last part of the desaturation curve during a VOT, while the first part of the \text{StO}_2\text{ downslope} did not show any difference between survivors and nonsurvivors. This may reflect a tissue hypometabolic status, which may be better elicited in the final part of the ischemic challenge.

Prospective nonrandomized observational study of the use of an impedance threshold device in patients with spontaneous respiration and hemodynamic instability

C Pantazopoulos\(^1\), T Floros\(^1\), N Archontoulis\(^1\), D Xanthis\(^2\), D Barouxis\(^2\), N Iacovidou\(^2\), T Xanthos\(^2\)

\(^1\)Laiko General Hospital of Athens, Greece; \(^2\)University of Athens, Medical School, Athens, Greece

**Introduction** The use of an impedance threshold device (ITD) in cardiac arrest victims has been shown to increase the systolic arterial pressure (SAP) by increasing venous return \([1]\). There are limited studies concerning the use of ITD in patients with spontaneous respiration and hemodynamic instability. The purpose of this study is to evaluate changes of hemodynamic parameters with the use of ITD in patients with spontaneous respiration and hemodynamic instability.

**Methods** A 5-month prospective nonrandomized observational study that included 50 adult patients with spontaneous respiration and hypotension in the emergency room and the wards of multiple causes except trauma. After measurement of the SAP and verification of hypotension \((\text{SAP} \leq 90 \text{ mmHg})\), a mask-style ITD was added. Hemodynamic parameters were evaluated every 1 minute and for 10 minutes after the intervention. Endpoint of the study was a change of patient’s SAP after application of ITD.

**Results** The SAP of patients that were included in the study increased 15 to 22 mmHg \((P < 0.05)\). Heart rate remained unchanged. Eighty percent of patients declared good to very good tolerance from ITD application.

**Conclusion** In this observational study of patients with spontaneous respiration and hypotension, ITD increased the SAP, while it seems that it was well tolerated by patients. Additional and larger studies will be needed in the future in order to investigate the benefits of ITD when used to patients with spontaneous respiration and hemodynamic instability.

Lactate in the burn patient

EH Herrero, M Sánchez, L Cachafeiro, A Agrifoglio, B Galván, MJ Asensio, A García de Lorenzo

Hospital La Paz, Madrid, Spain

**Introduction** Severe burns result in rapid loss of intravascular volume due to development of a severe capillary leak and hypovolemic shock. It is widely accepted that traditional markers, such as blood pressure and urinary output, are useful but do not sufficiently reflect global perfusion, regional microcirculation or reversal shock. Blood lactate concentration is widely used in ICUs as a reliable prognostic marker of global tissue hypoxia. Our aim is to determine whether the percentage of lactate clarified in the first 24 hours is valid as a guide for resuscitation.

**Methods** We prospectively studied 143 consecutive burn patients admitted to our Burn Unit. Sociodemographics and comorbidities data were recorded. Clinical data were collected to calculate the Acute Burn Severity Index. Resuscitation according to the Parkland formula was guided by a urinary output of 0.5 to 1 ml/hour and the results of monitoring the blood pressure. Crystalloid solution (Ringer’s acetate) was given exclusively during the first 24 hours. Early surgical excision of burn eschar and early coverage of excised burn wounds with autografts was performed. Initial and subsequent serum lactate levels were measured to calculate lactate clearance according to the formula: lactate basal – lactate at 24 hours / lactate basal × 100. The primary outcome was mortality.

**Results** During a period of 2 years we studied 143 patients; their mean age was 46.98 ± 19.38 years, mean TBSA burn injury of the study population was 22.82 ± 20.25. The flame was the most frequent mechanism. A total of 83 patients were in mechanical ventilation and 13.6% of them developed ARDS. The mortality range in the study group was 17%. Serum lactate at admission ≥2 mmol/l was associated with 31.3% mortality versus 6% in patients with a serum lactate at admission <2 mmol/l \((P < 0.05)\). Length of time to lactate normalization variable is associated with mortality \((P < 0.02)\). The average lactate normalization time was 4.6 days in nonsurvivors while in survivors it was 2.02 days. A relation does not exist between the lactate clearance and mortality in all patients.

**Conclusion** The length of time to lactate normalization in the severe burn patient is a marker of survival and a simple parameter to guide the endpoint of resuscitation; however, the percentage of lactate clarified in the first 24 hours is not valid.

**P146**

Blood lactate normalization following venoarterial ECMO institution for refractory cardiogenic shock

M Bottiroli, D Decaria, T Maraffi, S Nonini, F Milazzo, R Paino

Anestesia Rianimazione 3, A.O. Niguarda, Milan, Italy

**Introduction** Venoarterial (VA) ECMO is used to support patients with refractory cardiogenic shock (CS). Elevated lactate level (>2 mmol/l)
an indicator of end-organ hypoperfusion. We hypothesize that the lactate (LAC) normalization had prognostic value in this cohort of patients.

**Methods** We performed a retrospective observational study on patients admitted to the ICU for refractory CS from January 2010 to November 2014. Patients with postcardiotomy and/or post-transplant CS were excluded. Demographics, clinical, hemodynamic and biochemical values were collected. LAC was measured on arterial blood before ECMO institution (LAC0) and after 48 hours (LAC48). Lactate clearance was calculated as follows: (LAC0 – LAC48) / LAC0 × 100. Data were analyzed by comparative statistic; sensitivity and specificity were tested with ROC.

**Results** Twenty-three patients underwent VA ECMO for refractory CS in the study period. Etiologies of CS were: 11 acute myocarditis, five acute myocardial infarction and seven acute decompenation of chronic cardiomyopathy. The median time of ECMO was 10 days (4 to 15). Thirteen patients died during hospital stay and 10 survived. Three patients were bridged to LVAD and two to heart transplant; eight were bridged to recovery. The main cause of ICU death was multiple organ dysfunction (12/13). Nonsurvivors showed significantly higher LAC0 (5.2 to 6.0) vs. 8 (5 to 11), P = 0.021. Lactate clearance at 48 hours was not significantly different between survivors and nonsurvivors (79%, 95% CI = 67 to 86 vs. 60%, 95% CI = 32 to 72, P = 0.08). However, LAC48 was predictive for ICU mortality (AUC 0.82; 95% CI = 0.64 to 1.0; P = 0.011). ROC curve analysis identified the accuracy was highest by setting the lactate <2 mmol/l. Patients that did not normalize lactate (LAC <2 mmol/l) after 48 hours despite hemodynamic restoration had poorer outcome at 30 days, as is shown in the Kaplan–Meier curve (Log rank P = 0.006) (Figure 1).

**Conclusion** Failing to normalize patient's LAC in the first 48 hours of VE ECMO assistance for CS is a predictor of ICU mortality. Targeting LAC level <2 mmol/l at 48 hours post ECMO institution might be a reasonable goal for these patients.

**Introduction**

Inotropes and vasoactive drugs in septic shock are commonly used to maintain cardiac output, tissue perfusion and oxygenation. We undertook this study with the purpose of evaluating an inotropic score as a predictor of mortality and morbidity among children who diagnosed septic shock.

**Methods** A multicenter retrospective chart review was performed in two pediatric ICUs. A total of 93 children with septic shock were recruited. Hourly doses of following inotropes were recorded for the first 48 hours after admission: dopamine, dobutamine, adrenaline and noradrenaline. The inotropic score for every hour, minimum, maximum and mean values for the first 24 hours, and subsequent 24 hours were calculated. In our analysis, the inotropic score was calculated as described by Wernovsky. We expanded this formula to include norepinephrine as follows: Wernovsky Inotrope Score = dopamine dose (μg/kg/minute) + dobutamine dose (μg/kg/minute) + 100 × epinephrine dose (μg/kg/minute). Our adjusted inotropic score = Wernovsky Inotrope Score + 100 × norepinephrine dose (μg/kg/minute).

**Results** Forty-two of 93 patients died. Age and sex were not different between survivors and nonsurvivors. Significantly higher mean and maximum inotropic score for the first 24 hours and first 48 hours were found in nonsurvivors than those of survivors (P < 0.05). Using 15 as a cutoff point for predicting mortality, the sensitivity and specificity were 69.76% and 50.98% respectively. The association between Prism scores and minimum, mean and maximum inotropic scores were statistically significant for 0 to 24 hours, 25 to 48 hours and 0 to 48 hours. Mean 0 to 24 hours and maximum 0 to 48 hours inotropic scores were weakly associated with prolonged ICU stay (P = 0.047, P = 0.042 respectively). There were no significant relationships between inotropic scores and receiving mechanical ventilation.

**Conclusion** The mean and maximum inotropic scores in the first 24 hours and 0 to 48 hours are an independent predictor of mortality in critically ill children with septic shock.
Conclusion SI is independently associated with 30-day mortality in a broad population of ED patients. Old age, hypertension and β-/Ca2+ channel-blockers weaken this association, but the association remains prognostic. SI ≥1 suggests substantial risk of 30-day mortality in all ED patients.

P149 Risk factors for severe vasodilatory shock after cardiac surgery

A Almeida, F Galas, J Fukushima, E Almeida, A Gerent, E Osava, C Park, R Nakamura, A Leme, M Sundin, R Kalil Filho, F Jatene, L Hajar
Heart Institute, São Paulo, Brazil

Introduction Vasodilatory shock is a well-known complication in patients who undergo cardiac surgery with cardiopulmonary bypass (CPB) and its occurrence is associated with higher morbidity and mortality. Despite that, clinical characteristics of vasoplectic shock and its spectrum of severity are poorly described. The aim of this study was to compare patients who developed mild to moderate vasoplectic shock with patients who developed a severe form and to identify predictive factors for the severe form of vasoplectic shock.

Methods We performed an observational study in 300 patients who underwent cardiac surgery with CPB and presented within the first 24 hours after surgery with refractory hypotension and used a vasopressor agent. Severe vasoplectic shock was defined as a requirement of norepinephrine higher than 1 μg/kg/minute or the use of two or more vasopressors. Baseline characteristics, laboratory, clinical and intraoperative data, such as amount of fluids, bleeding, blood transfusion, inotropes and length of CPB were collected at ICU admission. Logistic regression was performed using severe vasopletic shock as the outcome.

Results There were 46 (15%) patients who develop the severe form of vasoplectic shock within 24 hours after cardiac surgery. In a univariate analysis, patients with the severe form were more likely to be older, to receive more blood transfusion and inotropic agents, to have higher levels of serum lactate, lower hemoglobin concentration and lower SvO2 at the end of the procedure, lower cardiac output index, higher heart rate and higher levels of reactive C protein at ICU admission. These patients also experienced more postoperative organ dysfunction, had a longer length of ICU stay and higher mortality. There were no differences between patients regarding amount of fluids and length of CPB. In a multivariate analysis we identify age (OR = 1.04, 95% CI = 1.01 to 1.08, P = 0.016), intraoperative use of epinephrine (OR = 5.49, 95% CI = 2.42 to 12.43, P < 0.001), higher serum lactate at the end of the procedure (OR = 1.04, 95% CI = 1.01 to 1.06, P = 0.001) and intraoperative blood transfusion (OR = 5.06, 95% CI = 2.19 to 11.69, P < 0.001) as predictive factors for the severe form of shock.

P150 Preoperative treatment with levosimendan helps to evaluate myocardial reserves in cardiac surgical patients with chronic heart failure

A Eremenko, M Babaev, S Fedulova, S Dzemeshkevish
FSBSI Petrowsky NRCS, Moscow, Russia

Introduction The aim of the study was to assess the possibility of preoperative levosimendan (LS) administration in myocardial reserve evaluation and choice of the method of surgical treatment in patients with chronic heart failure (CHF).

Methods LS was used in 107 (female and male) patients (mean age 53 ± 3 years) as a component of CHF therapy to prepare them for the surgical intervention (2 to 4 days before surgery). In total, 44.9% of the patients had CHF caused by noncoronarogenic dilated cardiomyopathy and 55.1% by ischemic cardiomyopathy. Indication for LS therapy was left ventricular ejection fraction (EF) ≤35% (28 ± 6%). Seventy percent of patients had mitral insufficiency (MI), grades II to IV, 63% tricuspid insufficiency (Trl), grades II to III, 84% pulmonary hypertension (PH), 47% arterial hypertension, grades II to III, and 27% of the patients had left ventricular aneurysm. Mean level of BNP was 1,803 ± 124 pg/ml. LS was administered as i.v. infusion in doses of 0.025 to 1.1 μg/kg/minute without previous bolus injection. Mean duration of infusion was 27.5 ± 5.3 hours. After infusion all patients underwent control assessment of values. All patients were operated: 25 (23.3%) underwent reverse cardiac remodeling, 63 (58.9%) myocardium revascularization (MR) with mitral or aortic valve replacement, 17 (15.9%) MR and/or resection of left ventricular aneurism and two (1.9%) heart transplantation.

Results Heterogeneity of LS effects was registered in a number of values. The most significant positive effect which allowed one to evaluate myocardial reserve was demonstrated by decrease of PPA (93.5% of patients) and increase of EF (77.6% of patients). The most significant changes were also noted in decrease of TrI, PH and MI (in 53.2%, 36.6% and 36% of patients, respectively). In 69.2% of patients with noncoronarogenic dilated cardiomyopathy the effect of LS exposure was marked. In the majority of patients with ischemic cardiomyopathy the effect was moderate. In case of the absence of LS-positive effect, perioperative use of mechanical circulatory support was considered.

Conclusion Preoperative use of LS allows one to evaluate myocardial reserves and prepare high-risk patients with CHF for surgery. Our findings may serve as one of the additional criteria to choose the type of surgical treatment: reconstructive surgery (with or without perioperative mechanical circulatory support) or heart transplantation.

P151 Levosimendan versus dobutamine in cardiac surgery

MD Delgado-Amaya, EC Curiel-Balsera, CJ Joya-Montosa
Hospital Regional de Málaga, Spain

Introduction Early studies suggested a significant increase in survival in patients treated with levosimendan compared with dobutamine or placebo (LIDO, RUSSLAN and CASINO trials). However, two subsequent studies (SURVIVE and REVIVE II) have not confirmed these findings.

Methods A prospective observational study of all patients undergoing cardiac surgery at Malaga’s Regional Hospital from March 2009 to March 2013. We analyzed patients who used levosimendan compared with those that used dobutamine in the first hours after cardiac surgery. In which neither of these two drugs were used or surgical cases that arrived at the ICU with both inotropics. We analyzed demographic variables as well as clinical complications in the ICU and overall perioperative mortality of patients. We performed a second analysis using the propensity score, obtaining the probability of patients being treated with either drug, pairing each patient who received levosimendan with its nearest neighbor receiving dobutamine. Results We collected 875 patients: 331 received one of the two drugs, 50 received both drugs and 494 did not receive any drug. ICU mortality was 7.2% (levosimendan group) and 12.5% (dobutamine group), P = 0.1. After adjustment for severity and type of surgery, the use of levosimendan in the postoperative period was not a protective factor for ICU mortality (P = 0.18, OR = 0.5, 95% CI = 0.18 to 1.3). In the matched sample, mortality was 7.4% (levosimendan group) and 5.9% (dobutamine), P = 0.73. After logistic regression adjusted for severity, measured with EuroSCORE and type of surgery, levosimendan was not a protective factor for ICU mortality (P = 0.8, OR = 1.2, 95% CI = 0.26 to 5.45).

Conclusion In our environment, we have observed differences in the use of levosimendan compared with dobutamine (higher rate of men undergoing CABG, diabetes and worse EF). After homogenizing the sample of patients by propensity score, an effect on mortality is discarded and we observed a significant need for use of norepinephrine and a nonsignificant trend for prolonged mechanical ventilation and renal failure requiring renal replacement therapy, both probably related with the greatest need for vasopressors observed.
P152
Levosimendan: use, cost-effectiveness and outcome in a tertiary cardiothoracic centre
A Ranjan, N Bhudia, I McGovern, C Walker, L Kuppurao
Royal Brompton & Harefield NHS Foundation Trust, Harefield, London, UK

Introduction Levosimendan was originally developed for the treatment of decompensated heart failure in situations for which conventional therapy is not sufficient. It is an effective calcium-sensitising drug with vasodilatory and inotropic effects and improves cardiac contractility. Trials have shown positive outcome benefit with the use of levosimendan [1]. We reviewed the usage of levosimendan at our institution and outcome of these patients.

Methods We reviewed the use of levosimendan at Harefield from January 2013 through December 2013. Patient demographics, logistic EuroSCORE (Figure 1), diagnosis, surgical or intervention details, inotropic support, dosage and duration of levosimendan use, length of stay in the ICU, cost (Table 1) and patient outcome were collected.

Results Levosimendan was used in 30 patients, 23 (77%) male and seven (23%) female. Median age was 69 (59 to 72.8). Levosimendan was used post cardiac surgery, post angioplasty and in patients with ventricular assist devices (VAD) and extracorporeal membrane oxygenator (ECMO). Most of the patients received a standard regimen of 12.5 μg administered at a dose of 0.1 μg/kg/minute for 24 hours. Concurrent noradrenaline was used in most of the patients ranging from 0.02 to 0.2 μg/kg/minute. The median length of stay in the ICU was nine (6 to 14.3) days for survivors and 23.5 (7.5 to 36) days in nonsurvivors. Sixteen patients (55%) survived and were discharged from the hospital.

Conclusion We have successfully used this drug in high-risk patients during the perioperative period with good results without major complications. Levosimendan seems to reduce catecholamine requirement, the need for mechanical circulatory support, and the duration of critical care, which can justify the cost of this drug. It can be also useful in weaning patients from short-term VAD and ECMO. Larger studies are required in this area.

Levosimendan in the emergency department: a useful tool to improve cellular perfusion
G Devia, J Torres, S Lopez
Hospital Universitario Mayor, Bogotá, Colombia

Introduction Levosimendan is an inotropic seldom used in emergency departments (EDs). It has shown improved mortality in patients with shock [1] with few adverse effects [2]. This work denotes the experience of levosimendan use in the ED of Hospital Universitario Mayor between 2012 and 2014.

Methods We present a retrospective study which analyses the effect, after 24 hours, of levosimendan administration on perfusion parameters of 166 ED patients. Patients had to have shock diagnosis of any cause. Differences between the initial and final mean value of the following parameters were evaluated: lactate, central venous oxygen saturation (SvO2) and venoarterial difference of CO2 (DvaCO2). Data were stratified according to levosimendan categories (initial or rescue).

In addition, association between different variables with mortality was sought. Differences were considered statistically significant at probability levels below 0.05.

Results There were no differences in APACHE II values between patients who received levosimendan as initial therapy from those who received it as a rescue measure. A total of 41 patients fulfilled lactate normalization requirements (lactate <2.0 or clearance >50%) (Table 1). Forty-four patients reached normal values of SvO2 and 37 patients of DvaCO2 after levosimendan initiation. There were no associations between the normalization of lactate, SvO2 and DvaCO2 and different types of shock. Twenty-nine patients who received initial therapy with levosimendan normalized their lactate values and 12 who received it as a rescue therapy (P<0.05). Sixty-three patients developed hypotension, and none had adverse effects requiring discontinuation of the drug.

Hospital mortality was 47.7%. Variables associated with mortality in the study group were lactate value at admission (OR = 1.3, 95% CI = 1.0 to 1.7), the use of vasopressin after start levosimendan (OR = 7.5, 95% CI = 1.9 to 28.6) and the use of norepinephrine before starting (OR = 10.8, 95% CI = 1.9 to 60.7).

Conclusion Levosimendan use in the ED, as initial or rescue therapy, normalizes lactate values and improves the SvO2 after 24 hours, without an increase in adverse effects.

Milrinone role in treatment of septic shock
V Tomicic, L Zouein, J Espinoza, S Ugarte
Clinica Indisa, Santiago, Chile

Introduction The inotropic agents used in the ICU are dobutamine and milrinone; unfortunately, they have shown significant side effects when used for myocardial depression during septic shock. Our objective is to describe Mn behavior in septic shock.

Figure 1 (abstract P152). Logistic EuroSCORE of all patients.

Conclusion Levosimendan use in the ED, as initial or rescue therapy, normalizes lactate values and improves the SvO2 after 24 hours, without an increase in adverse effects.

Table 1 (abstract P153). Perfusion variables before and after levosimendan

*P<0.01. McNemar test.
Methods We reviewed 72 clinical records of patients with diagnosis of septic and mixed shock who received Mn through January to December 2013. Demographic, hemodynamic, metabolic and gasometric data were recorded before and after Mn infusion. The PICCO monitoring system was used. Data were expressed as mean and standard deviation. The statistical analysis used Student’s t test. P < 0.05 was considered significant.

Results Seventy-two patients were studied: 36.5% were women, mean and SD of age, APACHE II, mechanical ventilation days and long ICU stay were 67.3 ± 16 years, 18.5 ± 5.9 points, 14.9 ± 12.9 and 24.5 ± 21.9 days, respectively. A total 20.3% of the patients received dobutamine. Thirty-nine percent presented mixed shock. Global mortality was 23%. After Mn infusion: cardiac index (CI) increased: 3.1 ± 1 to 3.3 ± 1.1, cardiac rate increased: 82.4 ± 14.4 to 88.3 ± 18 and ScvO₂ increased: 71.1 ± 10.3 to 76.1 ± 7.3 (P < 0.05). PaCO₂, arteriovenous difference and lactate were reduced: 7.36 ± 3.3 to 6.04 ± 3.6 and 18.7 ± 14.9 ± 3.1 ± 9.1 (P < 0.05). CVP, MAP, RVSI, VSTI, EVLWI and base excess showed no significant difference. Mn initial average dose was 0.35 ± 0.13. NE before and after Mn infusion showed no significant difference: 0.11 ± 0.20 versus 0.12 ± 0.22.

Conclusion Mn optimizes cardiovascular performance in septic shock and mixed shock, without affecting hemodynamic variables and global tissue perfusion. In addition, we observed that the IC, ScvO₂, PaCO₂ arteriovenous difference and lactate are related variables.

Arrhythmia incidence and risk factors in critically ill patients
G Tasdemir, N Kilebek Girgin, A Aydin Kaderli, E Cizmeci, R Iscimen, F Kahveci, A Aydinlar
Uludag University Medical Faculty, Bursa, Turkey

Introduction Cardiac arrhythmias may be observed at any time during the ICU stay. The prognosis may suffer due to these arrhythmias. In our study, we aimed to evaluate incidence and risk factors of arrhythmias occurring in patients in the ICU.

Methods Patients treated in the ICU were included in the study if they fulfilled the following: age >18, no cardiac valvular disease, no cardiac surgery in the recent 6-month period, no history of myocardial infarction (MI), need for mechanical ventilation, and one or more organ failure. Demographic, hemodynamic and laboratory parameters, APACHE II score, presence of sepsis, acute renal failure, MI, and VIP during the ICU stay were recorded. Therapies used for arrhythmia and response to therapies were also recorded.

Results Two hundred and fourteen patients were included in the study. Twenty-six percent (n = 56) of patients had arrhythmias. Incidence was higher in females (P = 0.045). Average age of arrhythmic patients was 69 (19 to 86), and they were older than nonarrhythmic patients (P < 0.001). APACHE II scores were higher in arrhythmic patients (P = 0.001).

Conclusion Older age, higher APACHE II scores, trauma, CVE, VIP and sepsis increases arrhythmia risk in critically ill patients. Atrial fibrillation is the most frequent type of arrhythmia (53%), and the most frequently used medication was diltiazem (28.5%). The patients who had arrhythmias had a longer ICU stay (P = 0.021). The mortality rate for all patients was 48.1%. There was no statistically significant relationship between arrhythmia and mortality (P > 0.05).

Pulmonary hypertension, right ventricular dysfunction and acute heart failure: a portentous consortium
HD Michalopoulou, HM Michalopoulou, P Statmatis, E Kostetos, D Statmatis
Metaxa Hospital, Athens, Greece

Introduction Pulmonary hypertension and right ventricular dysfunction (RVD) are frequently encountered in patients with acute heart failure. We sought a better understanding of the coupling between RVD and pulmonary hypertension in the setting of acute decompensated heart failure (ADHF) as it might improve the prognostic stratification and influence the survival rates.

Methods Echocardiography was performed in 329 patients with ADHF and right ventricular function was assessed by measuring the right ventricular fractional area, and a right ventricular ejection fraction (RVEF) <35% was taken as the cutoff value for RV systolic dysfunction. The systolic pulmonary pressure (PASP) was calculated from the tricuspid regurgitation signal applying the modified Bernoulli equation, adaptive threshold for low amplitude QRS detection; QRS filter with an extended frequency range; management of VT alarm priorities.

Conclusion A majority of the FPs was linked to user settings and patient conditions. The algorithm changes resulted in a clear reduction of ECG algorithm-related FP alarms, while the magnitude of the reduction depends strongly on the settings at the bedside.

References
and pulmonary hypertension was considered as PASP >35 mmHg. Based on the values of PASP and RVEF, the study group was classified into four subgroups: group 1, normal PASP/preserved RVEF; group 2, high PASP/preserved RVEF; group 3, normal PASP/low RVEF; group 4, high PASP/low RVEF. The primary endpoint was all-cause mortality. The median follow-up was 18 months. Survival analysis was performed according to the Cox regression method, adjusted for age, gender, LV function, estimated glomerular filtration rate, troponin I, hemoglobin, serum sodium and BNP levels.

Results Pulmonary hypertension was found in 78% of the patients (median PASP: 53 mmHg). As compared with the patients with normal PASP the patients with pulmonary hypertension were more likely to be in New York Heart Association functional class (NYHA) III or IV (86% vs. 49%, P < 0.0001), had a lower RVEF (23 ± 9% vs. 32 ± 8%, P < 0.0001), and had significantly higher BNP levels (280 ± 107 pg/ml vs. 540 ± 320 pg/ml, P < 0.0001). In a Cox model, compared with patients with normal right ventricular function and without pulmonary hypertension (group 1), the adjusted hazard ratio for mortality was 3.1 (95% CI: 1.6 to 4.2, P < 0.01) in group 2, 0.3 (95% CI: 0.2 to 1.9, P = 0.3) in group 3 and 4.2 (95% CI: 1.9 to 6.1, P < 0.0001) in group 4.

Conclusion Among ADHF patients, the coupling of pulmonary hypertension and RVD carries an incremental risk, having a portentous impact on the survival rate.

P158
High-sensitive cardiac troponins and CK-MB concentrations in patients undergoing cardiac surgery

N De Mey, I Brandt, C Van Mieghem, K De Decker, G Cammuc, L Foubert
OLV AALST, Aalst, Belgium

Introduction Hs-cTn is the new standard cardiac biomarker for the diagnosis of myocardial necrosis. We conducted a prospective study to compare the course and values of Hs-cTn and CK-MB after CABG and OPCAB. We also evaluated the relationship between values >10 × 99th percentile URL of CK-MB and Hs-cTn as a possible marker for perioperative myocardial infarction.

Methods All adult patients undergoing cardiac surgery between February and August 2014 were included. Exclusion criteria were urgent surgery, GFR <60 ml/minute/1.73 m2, CK-MB >4 μg/l and/or >10 × 99th percentile URL of CK-MB and Hs-cTn as a possible marker for perioperative myocardial infarction.

Results Of the 93 patients admissible for inclusion, 40 in the CABG and 27 in the OPCAB group met all inclusion criteria in this preliminary dataset. CK-MB values are higher from ICU arrival up to T24 versus baseline in both CABG and OPCAB (P < 0.0001) with a peak at T3. For Hs-cTn, ICU up to T48 values are higher (P < 0.01) in CABG with a peak at T6, and from T3 to T48 in OPCAB (P < 0.05) versus baseline (Figure 1). In CABG patients CK-MB levels are higher versus OPCAB from ICU up to T12 (P < 0.03), and from ICU to T48 for Hs-cTn levels (P < 0.02). In 39 CABG patients (97.5%) and 10 OPCAB patients (71.4%) all individual Hs-cTn values are above 140 ng/l (= 10 × 99th percentile of URL).

Conclusion Both CK-MB and Hs-cTn levels increase significantly after cardiac surgery. Postoperative Hs-cTn values exceed the 10 × 99th percentile of URL in nearly all CABG patients. Our data show an important discrepancy between the 10 × 99th percentile of URL in CABG and OPCAB patients. Our data show an important discrepancy between the 10 × 99th percentile of URL in CABG and OPCAB patients.

Analytical and diagnostic characteristics of the high-sensitivity PATHFAST troponin I assay

E Spanuth1, R Thoma2, E Giannitsis3
1DiaNeering GmbH, Heidelberg, Germany; 2Mitsubishi Chemical Europe, Düsseldorf, Germany; 3University of Heidelberg, Germany

Introduction The POC PATHFAST cTnI assay (Mitsubishi Medience, Japan) has shown promising analytical validity. We thought to evaluate whether the assay could be classified ‘highly-sensitive’.

Methods cTnI was determined using PATHFAST in 120 healthy individuals (60 men and 59 women, 21 to 69 years old, median 42 years). Cardiac disorders were excluded by cardiac magnetic resonance imaging. The diagnostic characteristics were investigated by determination of cTnI and cTNT (Roche hs-cTnT) in 181 patients admitted to the chest pain unit at presentation, and 3 and 6 hours later.

Results The results were related to the discharge diagnoses.

Results

The cTnI concentrations measured in the control group ranged from 0.4 to 17.2, mean 2.1 (95% CI: 1.6 to 2.6) ng/l, without age dependency. Men revealed higher levels than women, means (IQR) were 2.8 (1.2 to 2.6) and 1.1 (0.7 to 1.3) ng/l. The CLSI nonparametric method revealed a 99th percentile value of 16 ng/l. The quantification of cTnI above the LoD (1.0 ng/l) and below the 99th percentile was possible in 79 of 120 individuals. The imprecision profile according to NCCLS revealed 20%, 10% and 5% CVs at concentrations of 2, 3 and at 20 ng/l, respectively. The discharge diagnosis was NSTEMI in 71 patients. The cTnI median values at 0, 3 and 6 hours were 46, 166 and 399 ng/l, respectively. AUC values at 0, 3 and 6 hours were 0.923, 0.964 and 0.969 for hs-cTnT and 0.919, 0.962 and 0.958 for cTnI, respectively. The cTnI revealed AUC values of absolute changes from admission to 3 hours and from admission to 6 hours were 0.920 and 0.931, respectively.

Conclusion The PATHFAST cTnI demonstrated complete fulfillment of the analytical criteria for high-sensitive cTn assays: The imprecision (CV) at the manufacturer-recommended 99th percentile value was 5%. The quantification of cTnI in was possible in 65.8% of healthy individuals. The examination of the diagnostic characteristics revealed complete concordance with the hsTnT assay for detection of NSTEMI and for assessment of absolute changes of cTn values (rise and/or fall) in NSTEMI patients. PATHFAST cTnI showed highly sensitive detection of NSTEMI with increasing sensitivity at admission and after 3 to 6 hours, not going along with decreased specificity. The PATHFAST cTnI might be useful at the point-of-care setting for early rule-in and rule-out diagnosis of NSTEMI.

P160
Combining therapeutic hypothermia and primary coronary intervention in comatose survivors of ventricular fibrillation due to ST-elevation myocardial infarction

R Krafelj, M Noc
University Clinical Center, Ljubljana, Slovenia

Introduction Primary percutaneous coronary intervention (PPCI) is the preferred reperfusion strategy for ST-elevation acute myocardial infarction (STEMI). In comatose survivors of cardiac arrest, mild induced hypothermia (MIH) improves neurological recovery.
Methods A total of 112 patients undergoing PPCI and MIH were compared with 32 comparable consecutive patients who underwent PPCI but no MIH. We hypothesized that combining both methods lead to better survival rate. MIH was induced (propofol, fentanyl, saline 4 ml/kg BW, 2°C) and maintained for 24 hours, targeting 32 to 34°C. Spontaneous rewarming was allowed (0.5°C).

Results There were no significant differences between the MIH and Control group in general characteristics, cardiac arrest circumstances and angiographic features. Except for decreases in heart rate during Control group in general characteristics, cardiac arrest circumstances, arterial pressure, peak lactate (7.7 vs. 6.2 mmol/l; \( P = 0.36 \)), need for vasopressors (57% vs. 41%; \( P = 0.09 \)), aortic balloon counterpulsation (13% vs. 22%; \( P = 0.19 \)), repeat cardioversion/defibrillation (17% vs. 25%; \( P = 0.30 \)). There was lower incidence of inotropic use (36% vs. 59%; \( P = 0.01 \)) and use of antithrombocytopenia (11% vs. 53%; \( P = 0.002 \)). There was no difference in FiO\(_2\) during mechanical ventilation and in renal function. See Table 1.

Table 1 (abstract P160). Survival after 12 months

<table>
<thead>
<tr>
<th></th>
<th>MIH</th>
<th>Control</th>
<th>( P )</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPC 1/2</td>
<td>50 (45%)</td>
<td>5 (15%)</td>
<td>0.002</td>
</tr>
<tr>
<td>CPC 3/4</td>
<td>0</td>
<td>0</td>
<td>NS</td>
</tr>
<tr>
<td>Cardio</td>
<td>20 (18%)</td>
<td>6 (19%)</td>
<td>0.95</td>
</tr>
<tr>
<td>CNS</td>
<td>18 (16%)</td>
<td>17 (53%)</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

Conclusion Hospital survival with CPC 1/2 was significantly better in the MIH group (45% vs. 15%; \( P = 0.01 \)). Our study clearly demonstrates that PPCI and MIH are feasible and may be combined safely in comatose survivors of ventricular fibrillation in STEMI setting. Such strategy improves survival with good neurological recovery.

Synthesized 18-lead electrocardiogram as routine myocardial ischemia detection in an emergency department: a preliminary evaluation in Europe

N Eppe, R Levy, M Vandoorslaert, B Kerzmann, J Rodrigues de Castro, T Scottiaux, JF Adam
Clinique Notre-Dame de Grâce, Gosselies, Belgium

Introduction Standard 12-lead electrocardiogram (ECG) is, with biomarkers, the most accurate method in the diagnosis of acute coronary syndrome (ACS). However, posterior (V7-V8-V9) and right (V3R-V4R-V5R) derivations are not systematically performed due to the time-consuming procedure involved, despite major therapeutic implications (fluid loading instead of nitrates use in right ventricular involvement) and published guidelines [1]. Recently, an 18-lead ECG system, standard 12-lead ECG and six additional synthesized leads (assessing posterior and right ventricular areas) in only one recording procedure has been developed. The reliability of this material (ECG 2550; Nihon Kohden Co. Ltd, Japan) was already validated in this indication in an Asian population [2,3].

Methods We conducted a prospective, observational study with patients admitted to our emergency department (ED), during a 6-month period. Requirement for ECGs was guided by physician’s discretion according to patient’s history. All patients with chest pain, dyspnea, palpitations, disturbance of consciousness, malaise or abdominal complaint underwent synthesized 18-lead ECG within 10 minutes of ED arrival. The aim of the study was to evaluate the effectiveness of the synthesized 18-lead ECG as an ischemia triage tool in the ED, and particularly the ability to early detect a right ventricular involvement.

Results Of the 3,833 nontraumatic patients treated in the ED, 3,196 were adults. In this adult population, 500 ECGs were performed in patients whose symptoms suggest ACS. The median age was 62.3 years and the sex ratio was 1.16. Clinical presentation was chest pain (31%), dyspnea (14%), palpitations (5%), disturbance of consciousness (3%) or others (47%). Fifty-six (11.2%) were diagnosed as ACS, including 20 ST-elevation myocardial infarction (STEMI), 28 non-STEMI and eight unstable angina. Of the 20 STEMI patients, eight (40%) and five (25%) were diagnosed as STEMI complicated by right ventricular and posterior wall ischemia respectively, which means that these complications could have been missed by standard 12-lead ECG.

Conclusion Eighteen-lead ECG with synthesized right-sided and posterior precordial leads was an efficient method to diagnose ACS in a Caucasian population within 10 minutes of ED arrival. It is particularly performant to detect right ventricular ischemia early, which can modify acute therapeutic strategy.

Peak systolic blood flow disturbances were estimated by the transtemporal approach in the MCA M1 segment. We determined lumen (TCD). All patients underwent duplex scan of extracranial portions of melitus; and craniospinal trauma and syncope. Study of cerebral heart disease; arrhythmia; large changes in haemorheology; diabetes criteria: potentially haemodynamically significant stenosis; congestive preeclampsia; control group: 72 healthy women with normal pregnancy, in pregnancy complicated by preeclampsia. Revealed that at the cutoff level of –12.46%, SGL identifies LV R– with a 1.63 (1.15 to 2.31) (P < 0.001) and OR: 1.85 (1.24 to 2.76) (P < 0.001), respectively. The analysis of ROC curves revealed that at the cutoff level of –12.46%, SGL identifies LV R– with a sensitivity of 81% and a specificity of 86% (AUC = 0.88; 95% CI: 0.79 to 0.96; P < 0.001) (Figure 1).

Conclusion SGL assessment in the first days after primary PCI is useful in the prediction of LV R– independently of the myocardial infarction localization.

P163
Analysis of the interhospital transfer times in patients with ST-elevation acute coronary syndrome for undergoing urgent coronarography
FM Acosta Diaz, O Moreno, M Muñoz, R Fernandez, J Soto, M Colmenero
San Cecilio University Hospital, Granada, Spain

Introduction The aim was to analyze the related assistance times to transfer patients with ST-elevation acute coronary syndrome (STEMI) referred to another hospital with a hemodynamics unit (HU) for performing emergency catheterization (primary or rescue PCI).

Methods A consecutive registry of patients seen in 2013 (January to October) in the ICU of a hospital without a HU. The total transfer time is considered from the call to the Emergency Coordination Center until arrival at the HU. In turn, this time is divided into activation time, arrival time of the relocation team, patient preparation time and transfer time. In the case of primary PCI, the door-to-balloon time was estimated by adding to the total transfer time the initial assessment and completion time of catheterization and balloon inflation. The times are expressed in minutes as the median and interquartile range.

Results During 10 months of 2013, we treated 162 STEMI. Of these, 104 had evidence of reperfusion (64%). Primary PCI was performed in 24 patients (23%), of which 10 were transferred from the hospital to the HU. Fibrinolytic therapy was used in 62 patients (59%), of these 20 (32.2%) required rescue PCI. The transfer time for primary PCI was 0:39:44 (0:31:41 to 0:44:32) minutes. The transfer time for rescue PCI was 0:38:56 (0:37:25 to 0:51:29) minutes. The door-to-balloon time estimated for primary PCI was 80 minutes.

Conclusion Times for interhospital transfer of patients with STEMI who had undergone urgent catheterization are within the range considered optimal. In the case of primary PCI, times are lower than the 90 to 120 minutes recommended practice guidelines.

P165
Prognostic comparison of tissue Doppler indices of diastolic dysfunction and cardiac biomarkers in septic shock
V Karali, V Voutsas, N Loridas, M Konoglou, M Papaioannou, A Alexiou, V Hatsiou, C Fitili, M Bitzani
Papanikolaou Hospital, Thessaloniki, Greece

Introduction Diastolic dysfunction as evaluated by tissue Doppler imaging (TDI), particularly by E/E' ratio (peak early diastolic transmural velocity/peak early diastolic mitral annular velocity) and mitral annular E-wave, is common and crucial in critical illness. Our prospective observational study assessed the prognostic significance of TDI variables versus cardiac biomarkers, B-type natriuretic peptide (BNP), troponin-T (Tnt) and investigated determinants of plasma BNP rise, in septic shock.

Methods Twenty-seven mechanically ventilated adult patients admitted to our ICU were evaluated within 72 hours of evolving septic shock. Patients underwent two transthoracic echocardiographies within 72 hours of the onset of septic shock: shortly after diagnosis and 24 hours later (confirmatory), alongside relevant measurements of cardiac biomarkers. Peak mitral inflow E and A velocity waves were recorded using pulsed-wave Doppler at the mitral valve tips from the apical four-chamber view, peak early (E') and late (A') diastolic myocardial velocities were obtained by TDI at the septal mitral annulus in the apical four-chamber view. E/E' was calculated. P <0.01 was reported as statistically significant.

Results Mean ± SD APACHE II score was 21.22 ± 7.28, mean ± SD admission SOFA score was 10.25 ± 2.76. Hospital mortality was 55%. Nonsurvivors had increased E/E' (15.56 ± 1.48; P <0.00001) and reduced E' 6.32 ± 0.68 cm/sec (P <0.0001) compared with survivors, who exhibited inverse correlations with an E/E' significantly lower (9.30 ± 2.88) and higher E' (9.01 ± 0.85 cm/sec). In contrast, BNP and TnT levels displayed remarkably lower statistical significance in nonsurvivors (P = 0.005, P = 0.007 respectively). The ROC curves had an area under the curve of 0.98 for the E' and 0.92 for the E/E'. Vasopressor management (noradrenaline dose) (P = 0.001), fluid balance (P <0.001) and E/E' (P = 0.00004) were independent predictors of plasma BNP concentration.

Conclusion Diastolic dysfunction as evaluated by E/E' and E' constitutes a major independent predictor of outcome in septic shock, compared with cardiac biomarkers, suggesting that echocardiographic techniques assessing diastolic dysfunction in sepsis may replace cardiac biomarkers for mortality prediction. Fluid balance, vasopressor management and diastolic dysfunction are independent predictors of BNP elevation in septic shock. Our findings should be confirmed by an extended prospective study.

Accidental intra-arterial injection: an under-reported preventable never event
M.Mariyalaviam, A.Hutton, P.Young
Queen Elizabeth Hospital, Kings Lynn, UK

Introduction Depending upon the medication administered, accidental administration of medication into the arterial line can cause devastating complications. This wrong-route injection is a never event in the UK but may be under-reported especially when occurring in the unconscious patient who may not notice associated pain temporarily. Under-reporting may occur because resultant complications may be delayed a number of hours and the accountable healthcare worker may not recognise or choose not to report the error. In 2008 the UK National Patient Safety Agency (NPSA) reported only 76 incidents related to poor sampling technique but few wrong route arterial injections. Of these 21% suffered moderate to severe harm [1]. The NPSA suggests that training and the use of clear labelling alongside red arterial tubing and standard red lock caps be used to prevent arterial sampling errors.

Methods In 2014, we conducted a national postal survey of ICUs in the UK to attempt to determine the rate of accidental intra-arterial injections. The survey was sent to the clinical director of each ICU and they were asked whether they were aware of any unintentional arterial line injection having occurred in their hospital in the last 5 years.

Results Of the 56 ICUs that responded, 16 (28.5%) reported that they had personally seen an accidental injection into the arterial line.

Conclusion Despite the arterial line safety recommendations made by the NPSA in 2008, we demonstrate that intra-arterial injection is still a problem and that it remains under-reported. Our incidence is likely to be an underestimate as it relies on the recollections of a single individual in each institution. Medical errors can be mitigated by consideration of human factors and system engineering to improve patient safety. A focus on clinical awareness, colour coding and training may lead to improvements; however, institutions and clinical directors also bear a responsibility to prevent never events and a number of engineered solutions are now available such as needle-free non-injectable arterial sampling devices to protect the healthcare environment and make this error impossible [2,3].

Room temperature transpulmonary thermodilution (TPTD) with increased indicator 20 ml TPTD bolus compared with standard TPTD with 15 ml iced saline: a prospective observational study
W.Huber, E.Maendl, A.Beitz, M.Messer, T.Lahmer, B.Henschel, W.Huber, A.Breitling, B.Henschel, S.Mai, S.Goetz, J.Tschirdewahn, J.Frank, A.Beitz, R.MSchmid
Klinikum rechts der Isar, Technical University of Munich, Germany

Introduction Use of ice-cold saline is assumed to provide best accuracy of TPTD to obtain the cardiac index (CI), global end-diastolic volume (GEDVI) and extravascular lung water (EVLWI). However, room-temperature injectate might facilitate TPTD outside the ICU. A recent study [1] showed acceptable bias and percentage error (PE) for CI-room derived from TPTD with 15 ml room temperature saline compared with CI-cold using 15 ml iced saline for TPTD. However, GEDVI-room and EVLWI-room had borderline PE values close to 30%, and the bias of GEDVI-room markedly increased with higher values of GEDVI and in case of femoral CVC. Since imprecision of TPTD-room might be reduced by a larger volume of injectate, it was the aim of our study to compare CI, GEDVI and EVLWI derived from TPTD using 20 ml room temperature injectate with standard TPTD with 15 ml iced saline.

Methods In 31 patients 236 sets with two 20 ml TPTDs with 21°C and subsequently two standard TPTDs with 4°C saline were obtained using the PICCO-2 device with the latest algorithm correcting GEDVI for femoral TPTD (Pulsion Medical Systems, Germany).

Results Fifteen female and 16 male patients, APACHE II score 21 ± 7. Mean values of CI (4.02 ± 0.98 vs. 3.96 ± 0.91 l/minute*m²; P < 0.001), GEDVI (800 ± 166 vs. 796 ± 163 ml/m²; P = 0.011) and EVLWI (10.3 ± 3.7 vs. 9.7 ± 3.6 ml/kg; P < 0.001) were slightly higher when measured at room temperature compared with cold saline. Mean bias and PE values were 0.06 ± 0.37 l/minute*m² and 18.6% for CI, 4 ± 81 ml/m² and 20.2% for GEDVI and 0.3 ± 1.1 ml/kg and 22.7% for EVLWI. Bias values in case of femoral compared with jugular indicator injection were not significantly different for CI (0.04 ± 0.41 vs. 0.11 ± 0.30 l/minute*m²; P = 0.161) and EVLWI (0.56 ± 1.19 vs. 0.42 ± 1.07 ml/kg; P = 0.492). Bias for GEDVI-room was significantly lower for femoral CVC compared with jugular indicator injection (~60 ± 81.1 vs. 18.9 ± 78.3 ml/m²; P = 0.008).

Conclusion Compared with previous data using 15 ml room-temperature injectate, our data with 20 ml room-temperature injectate in general provide acceptable bias and percentage error when compared with standard TPTD with 15 ml iced saline. This also applies for femoral CVC room-temperature TPTD which might also be related to a new PiCCO-2 algorithm correcting for femoral CVC site.

Transpulmonary thermodilution-derived haemodynamics in patients with liver failure: a prospective study in 351 patients
W.Huber, A.Breitling, B.Henschel, S.Mai, S.Goetz, J.Tschirdewahn, J.Frank, A.Beitz, R.MSchmid
Klinikum rechts der Isar, Technical University of Munich, Germany

Introduction Patients with acute or chronic liver failure are considered to have altered pattern of haemodynamics. Nevertheless, there is a lack of studies systematically investigating haemodynamics in patients with liver failure. Therefore, it was the aim of this study to compare transpulmonary thermodilution (TPTD)-derived haemodynamics of 112 patients with acute or chronic liver failure with 239 patients without liver failure.

Methods We analyzed a prospectively maintained database including 6,016 TPTD measurements in 351 patients. To account for different numbers of TPTDs in different patients, comparison of first measurements of patients with and without liver failure was the primary endpoint. Statistics: Wilcoxon test for unpaired samples; IBM SPSS Statistics 22.

Results A total of 207 male and 144 female patients, APACHE II score 21 ± 7, 62 ± 14 years old, one to 126 TPTDs per patient. Diagnosis: cirrhosis/liver failure n = 112 patients (31.9%), sepsis 55 (15.7%), ARDS 46 (13.1%), GI affection 21 (6.0%), various 98 (27.9%). Patients with liver failure were slightly younger than the other patients (59 ± 11 vs. 64 ± 15 years; P < 0.001). All other baseline characteristics were comparable including APACHE II (20 ± 7 vs. 21 ± 8; NS), SAPS 39 ± 12 vs. 41 ± 14; NS, height (172 ± 9 vs. 170 ± 9 cm; NS) and weight (76 ± 20 vs. 73 ± 17 kg; NS). Among haemodynamic parameters, preload markers GEDVI (753 ± 168 vs. 790 ± 226 ml/m²; P = 0.182) and CVP (14.4 ± 8.8 vs. 14.9 ± 7.1 mmHg; P = 0.250) were comparable. Despite comparable preload parameters, the following parameters were significantly different: patients with acute or chronic liver failure had significantly higher cardiac index (4.3 ± 3.3 vs. 3.3 ± 1.3 l/minute*m²; P < 0.001), stroke volume index (50 ± 15 vs. 37 ± 15; P < 0.001), pulse pressure (75 ± 19 vs. 65 ± 21 mmHg; P = 0.021) and cardiac power index (0.7 ± 0.24 vs. 0.60 ± 0.28 W/m²; P < 0.001). By contrast, MAP (77 ± 15 vs. 80 ± 15 mmHg; P = 0.045), SVR (1,305 ± 638 vs. 1,877 ± 698 dyne/s/cm⁵*m²; P < 0.001) and heart rate (84 ± 19 vs. 92 ± 22/minute; P < 0.001) were significantly lower in patients with liver failure.

Conclusion Our data derived from a large TPTD database demonstrate markedly different haemodynamics in patients with cirrhosis or acute liver failure with the only exception of static preload markers GEDVI and CVP. These findings should be considered in instable patients with liver failure.
P170
Measurement of cardiac output in children: comparison between direct Fick method and pressure recording analytical method: preliminary report
J Alonso Iñigo1, F Escribá1, J Carrasco1, J Encarnación1, M Fas2, M Barberá1
1Hospital Universitario y Politécnico La Fe, Valencia, Spain; 2Hospital Universitario de la Ribera, Alzira, Spain

Introduction There are few methods of cardiac output (CO) estimation validated in children. The aim of this study is to investigate the reliability of an uncalibrated pulse contour method of CO estimation, the pressure recording analytical method (PRAM), in pediatric patients scheduled for diagnostic right and left heart catheterization, compared with the oxygen-direct Fick method.

Methods Cardiac index (CI) was simultaneously estimated by Fick, and PRAM applied to pressure signals recorded invasively from a femoral catheter. All measurements were performed in steady-state condition. PRAM CI measurements were obtained for 10 consecutive beats simultaneously during the Fick CI estimation. Agreement between Fick and PRAM was assessed using the Bland–Altman method. Correlation coefficient, bias, and percentage of error were calculated.

Results Forty-three CI measurements were performed in 43 patients. The data showed good agreement between CIFick and CIPRAM: $r^2 = 0.98$; bias –0.0074 l/minute/m$^2$; limits of agreement from –0.22 to 0.22 l/minute/m$^2$. The percentage error was 8%. Figure 1 shows the Bland–Altman plot.

Conclusion PRAM provides reliable estimates of cardiac output in hemodynamically stable pediatric cardiac patients compared with the Fick method.

Potential role of jugular vein echographic assessment for central venous pressure estimation
P Balsorano, S Romagnoli, A De Gaudio
AOUC Careggi, Florence, Italy

Introduction Although recognized as a questionable indicator of the intravascular volume, central venous pressure (CVP) is integrated in many therapeutic algorithms for hemodynamic resuscitation of critically ill patients [1]. In an attempt to simplify CVP estimation, several clinical and ultrasonographic approaches have been suggested [2-5]. Nonetheless, the external jugular vein (EJV) circumference and area have not been evaluated. Considering the role of EJV visual assessment in the clinical estimation of CVP, we hypothesized that EJV ultrasound evaluation could be used to reliably estimate CVP.

Methods Patients with a CVC placed as part of clinical management were evaluated. EJV and internal jugular vein (IJV) measurements were performed at the left cricoid level. IJV and EJV were visualized in short axis view; diameters, circumferences and areas were obtained at end expiration with simultaneous CVP measurement. Measures were performed by a single trained operator, who was blind to CVP values.

Results Forty-eight patients were included. A poor correlation was found between CVP and IJV and EJV circumference and area in mechanically ventilated patients. A strong correlation was found between CVP and EJV circumference ($r$: 0.74; $P = 0.0004$; 95% CI: 0.421 to 0.897) and area ($r$: 0.702; $P = 0.0012$; 95% CI: 0.35 to 0.88) in spontaneously breathing patients. Conventional receiver-operating characteristic curves were generated to assess the utility of EJV circumference and area to predict low (≤8 mmHg) versus high (>8 mmHg) CVP values. AUC for EJV circumference and area was 0.935 ($P < 0.0001$; 95% CI: 0.714 to 0.997) and 0.87 ($P < 0.0001$; 95% CI: 0.63 to 0.98) respectively (Figure 1).

Conclusion These results highlight a potentially evolving role of EJV circumference and area in the hemodynamic management...
of spontaneously breathing patients. An important aspect of the
suggested approach is its simplicity, requiring basic technical skills
and making it suitable in any scenario where an ultrasound machine
is available.

Do intravascular hypovolaemia and hypervolaemia result in
changes in pulmonary blood volume?
JJ Vos1, TW Scheeren1, SA Loer2, A Hoeft3, JK Wietasch1
1University of Groningen, University Medical Center Groningen, the
Netherlands; 2Institute for Cardiovascular Research, VU University Medical
Centre, Amsterdam, the Netherlands; 3University of Bonn, Germany

Introduction Hypovolaemia is generally believed to induce centralisation
of blood volume. Therefore, we evaluated whether hypovolaemia
and hypervolaemia result in a change in central blood volume (that is,
pulmonary blood volume (PBV)) and we explored the effects on the
distribution between PBV and circulating blood volume (Vd circ).

Methods After local District Governmental Animal Investigation
Committee approval, blood volume was altered in both directions
randomly in steps of 150 ml (mild) to 450 ml (moderate) either by
haemorrhage, transfusion of blood, or infusion of colloids in six
Foxhound dogs. The anaesthetised dogs were allowed to breathe
spontaneously. Blood volumes were measured using the dye dilution
technique: PBV was measured as the volume of blood between the
pulmonary and aortic valve, and Vd circ by two-compartmental curve
fitting [1,2]. The PBV/Vd circ ratio was used as a measure of blood
volume distribution. A linear mixed model was used for analysing the
influence of blood volume alterations on the measured haemodynamic
variables and blood volumes.

Results A total of 68 alterations in blood volume resulted in changes in
Vd circ ranging from –33 to +31% (Figure 1). PBV decreased during mild
and moderate haemorrhage, while during transfusion PBV increased
during moderate hypervolaemia only. The PBV/Vd circ ratio remained
constant during all stages of hypovolaemia and hypervolaemia
(Figure 1).

Conclusion Mild to moderate alterations of blood volume result in
changes of PBV and Vd circ. However, against the traditional belief of
centralisation we could show that the cardiovascular system preserves
the distribution of blood between central and circulating blood volume
in anaesthetised dogs.

Comparative study between fluidless resuscitation with permissive
hypotension using the impedance threshold device versus
aggressive fluid resuscitation with Ringer lactate in a swine model
of hemorrhagic shock
C Pantazopoulos1, J Floros1, N Archontoulis1, D Xanthis1, D Barouki2, N Iacovidou1, T Xanthos2
1Laiko General Hospital of Athens, Greece; 2University of Athens, Medical
School, Athens, Greece

Introduction Permissive hypotension, which results in avoidance of
intravascular overpressure and thereby avoidance of platelet plug
dislodgement early in the clotting mechanism, improves the results
after trauma and hemorrhage. The research hypothesis is that augmentation of negative intrathoracic pressure with the use of an
impedance threshold device (ITD) will improve hemodynamic
parameters, without affecting permissive hypotension or causing
hemodilution. On the other hand, aggressive resuscitation with
Ringer lactate will cause hemodilution and intravascular pressures
that are very high for permissive hypotension, capable of platelet plug
dislodgement.

Methods Twenty anesthetized Landrace/Large-White pigs (19 ± 2 kg, 10
to 15 weeks) were subjected to a fixed hemorrhage (50% over
30 minutes). The pigs were randomly allocated into two groups (n =
10 per group). In group A, ITD was the only treatment for hypotension,
while in group B, an intravenous administration of 1 L Ringer lactate
was applied for treatment of hypotension. Hemodynamic parameters were
continuously assessed for the first 30 minutes after blood loss.

Results Mean systolic arterial pressures (SAPs) 30 minutes after
the intervention in each group were as follows: group A 80 ± 5 mmHg
and group B 90 ± 4 mmHg. Maximum SAPs during the assessment period
were: group A 89 ± 2 mmHg and group B 128 ± 5 mmHg. Mean pulse
pressure was higher in the ITD group versus the fluid resuscitation
group (P <0.05). After the assessment period, mean hematocrit
in group A was 24 ± 2%, while in group B it was 18 ± 1% (P <0.001).

Conclusion In our study, the ITD increased SAP and pulse pressure
without overcompensation. On the other hand, aggressive fluid
resuscitation led to a significant increase of SAP >100 mmHg capable
of clot dislodgement and in addition led to hemodilution.

Relation between global end-diastolic volume and left ventricular
end-diastolic volume
A Pironet1, P Monnion1, S Kamoi2, N Janssen1, PC Dauby1, JG Chase2,
B Lambermont1, T Desaive1
1University of Liège, Belgium; 2University of Canterbury, Christchurch, New Zealand

Introduction Measurement of global end-diastolic volume (GEDV) is
provided by cardiovascular monitoring devices using thermodilution
procedures. The aim of this study was to assess the relation between
this clinically available index and left ventricular end-diastolic volume
(LVEDV), which is typically not available at the patient bedside.

Methods Measurements were performed on six anaesthetised and
mechanically ventilated pigs. Volume loading via successive infusions
of saline solution was first performed and was followed by dobutamine
infusion. These two procedures provided a wide range of LVEDV values.
During these experiments, GEDV was intermittently measured using the
PiCCO monitor (Pulsion AG, Germany) during thermodilutions and
LVEDV was continuously measured using an admittance catheter
(Transonic, NY, USA) inserted in the left ventricle.

Results Table 1 presents the linear correlations obtained between
LVEDV and GEDV. These correlations are good to excellent, with
r values from 0.59 to 0.85. However, the coefficients of the linear
regressions present a large intersubject variability, which prevents
the precise estimation of LVEDV using GEDV. Nevertheless, variations in
LVEDV are well reproduced by the GEDV index. The variations in LVEDV
actually equal 21 to 48% of those in GEDV. The coefficient b is always
nonzero, indicating that some proportion of the GEDV index is actually
not linked to LVEDV.

Figure 1 (abstract P172).
and small bias between TTE-VTI and PiCCO-SVV (\(r_{\text{PiCCO}}\). There was a good agreement between decision-making as comparable with that measured by echocardiography but not with cases between echocardiography and NICOM.

We performed the TTE study. Differences among the three methods were assessed for significance using one-way ANOVA, Spearman's coefficient of change in CO (\(\Delta\text{COVE}\)) were highly correlated (\(r = 0.24, P = 0.20\); Figure 1A) but a good correlation and small bias between TTE-VTI and PiCCO-SV (\(r = 0.76, P < 0.0001\); Figure 1B). Applying the following indications for volume expansion (PiCCO and NICOM SV >15% and TTE VTI variability >15%) we found an agreement in 71% of cases between TTE and PiCCO and in 42% of cases between echocardiography and NICOM.

Conclusion Stroke volume produced by bio-reactance appeared to be comparable with that measured by echocardiography but not with PiCCO. There was a good agreement between decision-making as regards fluid administration between PiCCO and echocardiography. NICOM appeared unreliable in this setting.

LVEDV = \(a \times \text{GEDV} + b\).

**Conclusion** The results show that GEDV and LVEDV are generally well correlated, but the correlation coefficients are subject specific. A preliminary calibration step (for instance using echocardiography) is thus necessary to infer LVEDV from GEDV.

**Volume assessment in critically ill patients: echocardiography, bio-reactance and pulse contour thermodilution**

S Hutchings1, P Hopkins1, A Campanile2

1King's College Hospital, London, UK; 2Papworth Hospital, Cambridge, UK

**Introduction** We performed an evaluation of three devices used for assessment of volume status in critically ill patients in our institution: transthoracic echocardiography (TTE) (CX50; Philips Ultrasound), bio reactance (NICOM; Cheetah Medical) and pulse contour-based thermodilution (PiCCO; Pulsion Medical).

**Methods** Ten mechanically ventilated critically ill patients with PiCCO monitoring in situ and a good quality of images on transthoracic view were included. All study measurements were made in triplicate. A single trained cardiologist, blinded to the results from the other monitors, performed the TTE study. Differences among the three methods were assessed for significance using one-way ANOVA, Spearman’s coefficient and Bland–Altman analysis. All statistical analyses were performed using Graph-pad Prism 5 and \(P<0.05\) was taken as significant.

**Results** Ninety measurements were obtained. NICOM and TTE-derived stroke volume appeared well matched but PiCCO-derived values showed significant variation (\(F = 2.4, P = 0.09\)). There was no correlation between TTE velocity time integer (VTI) and NICOM stroke volume variation (SVV) (\(r = 0.24, P = 0.20\); Figure 1A) but a good correlation and small bias between TTE-VTI and PiCCO-SVV (\(r = 0.76, P < 0.0001\); Figure 1B). Applying the following indications for volume expansion (PiCCO and NICOM SV >15% and TTE VTI variability >15%) we found an agreement in 71% of cases between TTE and PiCCO and in 42% of cases between echocardiography and NICOM.

**Conclusion** Stroke volume produced by bio-reactance appeared to be comparable with that measured by echocardiography but not with PiCCO. There was a good agreement between decision-making as regards fluid administration between PiCCO and echocardiography. NICOM appeared unreliable in this setting.

**Introduction** Fluid administration is always important and difficult during the therapy of patients with sepsis. Accurately predicting fluid responsiveness and thus estimating whether the patient will benefit from fluid therapy seems particularly important. The present study intended to predict fluid responsiveness in patients with sepsis using a bio-reactance-based passive leg raising test, and to compare this approach with the commonly used central venous pressure (CVP) approach.

**Methods** This prospective, single-center study included 80 patients with sepsis from the Department of Critical Care Medicine of Zhejiang Hospital. Patients were randomly assigned to either Group A or Group B, with patients in Group A first taking the passive leg raising test and then taking the fluid infusion test, while patients in Group B followed the opposite protocol. NICOM was used to continuously record hemodynamic parameters such as cardiac output (CO), heart rate (HR) and central venous pressure (CVP), at baseline1, PLR, baseline2, and volume expansion (VE). Fluid responsiveness was defined as the change in CO (\(\Delta\text{CO}\)) >10% after VE.

**Results** CO increased during PLR (from 5.21 ± 2.34 to 6.03 ± 2.73 l/minute, \(P < 0.05\)); and after VE (from 5.09 ± 1.99 to 5.60 ± 2.11 l/minute, \(P < 0.05\)). The PLR-induced change in CO (\(\Delta\text{COPLR}\)) and the VE-induced change in CO (\(\Delta\text{COVE}\)) were highly correlated (\(r = 0.80 (0.64 to 0.90)\)), while the CVP and \(\Delta\text{COVE}\) were uncorrelated (\(r = 0.12 (–0.16 to 0.32)\)). The areas under the ROC curves of \(\Delta\text{COPLR}\) and \(\Delta\text{CVP}\) for predicting fluid responsiveness were 0.868 and 0.514 respectively. \(\Delta\text{COPLR}\) ≥10% was found to predict fluid responsiveness with a sensitivity of 86% and a specificity of 79%.

**Conclusion** Bioreactance-based PLR could predict fluid responsiveness in patients with sepsis, while CVP could not.

**P177**

**Bioreactance-based passive leg raising test can predict fluid responsiveness in patients with sepsis**

Acute changes of metabolic parameters after fluid challenge

T Nguyen, D De Bels, M Pussetto, P Cottignies, J Devriendt, C Pienakos
Brugmann Hospital, Brussels, Belgium

Introduction The detection of heart response to fluid administration is still a challenge in clinical practice. Changes in metabolic parameters may be useful to detect changes in cardiac output (CO) after fluid expansion.

Methods This is a prospective observational study in adult critically ill patients. CO was measured either by echocardiography or by a thermodilution method (PICCO, Swan–Ganz catheter). Hemodynamic measurements and blood gas analysis were obtained before and after a fluid challenge with either 1,000 ml crystalloid or 500 ml colloid. Arterial and central venous blood gas samples were taken simultaneously. Oxygen delivery (DO), oxygen consumption (VO2) and carbon dioxide production (VCO2) were calculated according to well-known formulas. Patients were divided into three groups (high responders, mild responders and nonresponders) according to their change in CO (≥20%, 10 to 20%, <10%, respectively).

Results We evaluated 27 patients, age 68 (95% CI: 61 to 74) and APACHE II score 22 (95% CI: 18 to 26). Seven patients were high responders, eight patients were moderate responders and 12 were nonresponders. DO2 was significantly increased in high responders (37 ± 35%, P < 0.01) as compared with moderate responders or nonresponders. Furthermore, nonresponders had a decrease in their DO2 (–10 ± 7%, P < 0.01). Functional moderate responders showed no change in their DO2 (1.6% ± 10, P = 0.73) after fluid challenge. We found no differences in changes in lactate levels and central venous oxygen saturation (ScvO2) between high responders, moderate responders and nonresponders. No differences in the changes of VCO2 or VO2/VCO2 ratio were found between high responders, mild responders and nonresponders too. Changes in DO2/VCO2 ratio were found to be significantly increased only in high responders (47 ± 73% vs. –14 ± 31%, P = 0.02) and not in mild responders (15 ± 54% vs. –14 ± 31%, P = 0.15) as compared with nonresponders.

Conclusion Only significant increases of CO (≥20%), after fluid administration, lead to improved oxygen delivery; DO2 may be decreased in nonresponders. The changes of ScvO2 and lactate levels do not track the changes of CO after fluid challenge. The DO2/VCO2 ratio may be a useful index to identify significant increases of CO after fluid challenge in cases where CO measurement is not feasible.

Global end-diastolic volume: a better indicator of cardiac preload in patients with septic shock

L Mirea, R Ungureanu, D Pavelescu, I Grintescu
Clinical Emergency Hospital of Bucharest, Romania

Introduction The aim of the study was to assess the value of the global end-diastolic volume (GEDV) evaluated by transvesical thermography as an indicator of cardiac preload comparing with stroke volume variation (SVV) in patients with septic shock.

Methods A prospective, observational study performed in an interdisciplinary ICU including 91 patients with septic shock. Hemodynamic monitoring was performed with a new calibrated pulse wave analysis method (VolumeView/3V1000; Edwards Lifesciences) in 37 patients (global GV1000) or with an uncalibrated method (FloTrac/Vigileo; Edwards Lifesciences) in 54 patients (group Vigileo) during the first 72 hours. All patients were receiving mechanical ventilation and vasopressors. Measurements were performed before and immediately after volume loading using 500 ml Ringer solution over a short period (<30 minutes).

Results A total of 211 fluid challenges were studied in 91 patients. We observed a significant relationship between the GEDV index before volume loading and the percentage increase in GEDV index in the EV1000 group and changes in GEDV index were significantly correlated with changes in stroke volume index (r = 0.75, P < 0.001), but an insignificant relationship between SVV variation and cardiac index variation (P = 0.05) in the Vigileo group.

Conclusion The transvesical thermography GEDV is a better indicator of cardiac preload than SVV in patients with septic shock.

Predicting fluid responsiveness in ICU patients: comparison of different parameters and cutoff limits using pulse power analysis assessment

H Barrasa, J Maynar, S Castrano, Y Poveda, P Garcia Domeleo, A Tejero, G Baziskueta, A Quintano, B Fernández Miret, M Iturbe, S Cabañes, F Fonseca
Alava University Hospital-Santiago, Vitoria, Spain

Introduction Dynamic parameters are becoming standard for fluid responsiveness assessment. Cutoff values are different in the literature. The aim was to assess the accuracy of different preload parameters to predict fluid responsiveness using pulse power analysis and to compare different levels of hemodynamic response due to passive leg raising (PLR) against the effect of a fluid challenge (FC).

Methods A prospective study in a 17-bed mixed ICU. Patients were fully ventilated and CO monitored with LiDCOplus® and underwent a FC due to hypotension and/or hypoperfusion and preload dependence (SVV and/or PPV >10%). PLR was performed before FC. Hemodynamic data were recorded prePLR, postPLR and postFC with O.1 l crystalloids. We compared different cutoff values of increase in CO and SV (10 to 15%) to assess the ability of PLR, SVV, PPV and CVP to predict the response to FC. Statistical analysis: continuous variables expressed as mean ± SD. Comparison before and after was done using a paired Student’s t test, and receiver operating characteristic (ROC) curves were generated by varying the discriminating threshold of each variable.

Results Thirty-one patients were included. Baseline parameters: MAP 70.5 mmHg (SD 13.3) 87% under catecholamine, SV 55.32 ml (SD 20.2), CO 5.2 l (SD 2), SVV 16.8% (SD 12), PPV 19.1% (SD 14), HR 96 bpm (SD 18) and CVP 9.2 mmHg (SD 2.5). In total, 41.9% of patients increased 15% CO after FC (selected as responders), 38.7% after the PLR. Differences in responders versus nonresponder patients were: baseline SVV (23.9 vs. 11.6; P = 0.02) and PPV (28.4 vs. 12.4; P = 0.01). Differences in SV and CO were not statistically significant. The best predictor to predict positive response to FC was PLR with cutoff 12.6% for CO increase: sensitivity 84.6% (95% CI = 65 to 101), specificity 94.4% (95% CI = 84 to 105) and AU ROC 0.94 (95% CI = 0.86 to 1.0). ROC was also good for SVV 0.835 (95% CI = 0.66 to 1.0; P = 0.002) and PPV 0.833 (95% CI = 0.681 to 0.985; P = 0.002) in this cutoff value. In SV increase, PLR, SVV and PPV had P <0.05, but with worse ROC. In addition, SVV <13% identified patients who will not increase MAP with FC: sensitivity 91.7% (95% CI = 76 to 107.3%), negative predictive value 93.5 (95% CI = 80.7 to 106). CVP failed to distinguish responders from nonresponders.

Conclusion Our results support the idea that a reversible FC (PLR; CO cutoff 12.6%) is best at identifying responder patients to a FC. Dynamic parameters (SVV/PPV) are also effective when appropriate. Beat-to-beat SV and CO using pulse power analysis is a valid tool for these tests.

Respiratory variations in aortic blood flow velocity and inferior vena cava diameter as predictors of fluid responsiveness in mechanically ventilated children using transthoracic echocardiography in a pediatric PICU

K El Halmi, M Negadi, H Bouguetouf, L Zemour, D Boumendil, Z Chentouf Mentouri
University Ahmed Benbella Oran 1, Oran, Algeria

Introduction Volume expansion remains the first treatment step for most children with acute circulatory failure in order to assess blood...
volume status. In this way, dynamic echocardiographic parameters have been proposed in mechanically ventilated children [1,2], using the heart–lung interactions. This study aimed to investigate whether respiratory variations of aortic blood flow velocity (DELTA Vpeak ao) and inferior vena cava diameter (DELTA IVC) by transthoracic echocardiography (TTE) could accurately predict fluid responsiveness in ventilated children.

Methods A prospective observational and interventional study conducted in a pediatric ICU investigated 40 mechanically ventilated children with preserved left ventricular (LV) function using TTE. Each patient had tachycardia, hypotension, oliguria, delayed capillary refilling or hemodynamic instability despite vasopressor drugs. Intervention: standardized volume expansion (VE).

Results The VE-induced increase in LV stroke volume was ≥10% in 28 patients (responders) and <10% in 12 patients (nonresponders). Before VE, the DELTA Vpeak ao and DELTA IVC in responders was respectively higher than that in nonresponders (18.75% (12 to 32) vs. 13.5% (6 to 16) and 31% (18 to 57) vs. 17.5% (14 to 25)). The prediction of fluid responsiveness was higher with DELTA Vpeak ao (ROC curve area 0.894 (95% CI = 0.756 to 0.969), P = 0.0001) and DELTA IVC (ROC curve area 0.869 (95% CI = 0.717 to 0.957), P = 0.0001). The best cutoff value for DELTA Vpeak ao was 16% with sensitivity and specificity predictive values of 88.5% and 90.9%, respectively. DELTA IVC was 20% with sensitivity and specificity predictive values of 88.5% and 90.9%, respectively.

Conclusion In this study, DELTA Vpeak ao and DELTA IVC were appropriate variables to predict fluid responsiveness by TTE in ventilated children.

P182 Prediction of fluid responsiveness in mechanically ventilated children using dynamic and static parameters by esophageal Doppler in a pediatric ICU

K Elhalimi, M Negadi, H Bouguetof, L Zemour, D Boumendil, Z Chentouf Mentouri
University Ahmed Ben Bella Oran 1, Oran, Algeria

Introduction Prediction of fluid responsiveness is defined by an increase in stroke volume (SV) of at least 10% after volume expansion. Dynamic [1] and static [2] esophageal Doppler (OD) parameters have been proposed in mechanically ventilated children to guide fluid therapy. This study aimed to compare dynamic parameters using the respiratory variation in aortic blood flow with static parameters using Doppler corrected flow times (FTc) obtained by OD.

Methods A prospective, observational and interventional study was conducted in our pediatric ICU from March 2012 to September 2014. We investigated 18 mechanically ventilated children with acute circulatory failure (ACF) – tachycardia, hypotension, oliguria, delayed capillary refilling or hemodynamic instability despite vasopressor drugs – using OD for each patient. Intervention: standardized volume expansion (VE).

Results The VE-induced increase in stroke volume was ≥10% in 14 patients (responders) and <10% in four patients (nonresponders). Before VE, the DELTA Vpeak ao in responders was higher than in nonresponders (19.5% (12 to 29) vs. 11.5% (7 to 13)), whereas FTc was lower in responders than in nonresponders (262.5 milliseconds (180 to 340) vs. 285 milliseconds (205 to 300)). The prediction of fluid responsiveness was higher with DELTA Vpeak ao (ROC curve area 0.964 (95% CI = 0.756 to 1.000), P = 0.0001) than with FTc (ROC curve area 0.562 (95% CI = 0.314 to 0.790); P = 0.7203). The best cutoff value for DELTA Vpeak ao was 13% with sensitivity and specificity predictive values of 85.7% and 100%, respectively; and the best cutoff value for FTc was 265 milliseconds with sensitivity and specificity predictive values of 57.1% and 75%, respectively.

Conclusion In our study, DELTA Vpeak ao was the most appropriate variable to predict fluid responsiveness by OD in ventilated children with ACF.

P183 Fluid management in mechanically ventilated children with acute circulatory failure based on the pleth variability index in a pediatric ICU

H Bouguetof, M Negadi, K El Halimi, L Zemour, D Boumendil, Z Mentouri
University Ahmed Ben Bella Oran 1, Oran, Algeria

Introduction The pleth variability index (PVI) is a new dynamic index obtained by automatic estimation of respiratory variations in the pulse oximeter waveform amplitude. This noninvasive and continuous hemodynamic monitoring has been recently proposed in mechanically ventilated patients to guide fluid therapy. We recently acquired a PVI monitor in 2014. PVI is calculated by measuring changes in perfusion index (PI) during the respiratory cycle as follows: PVI = (PImax – PImin) / PImax × 100. This study aimed to investigate whether PVI at baseline can predict fluid responsiveness.

Methods In our pediatric ICU we started a prospective and observational study. Between January and November 2014, nine mechanically ventilated children were investigated using PVI and transthoracic echocardiography for each patient with acute circulatory failure (ACF): tachycardia, hypotension, oliguria, delayed capillary refilling or hemodynamic instability despite vasopressor drugs. Intervention: standardized volume expansion.

Results Significant changes in stroke volume were observed after volume loading (VL) ≥10% in eight patients (responders (R)) and <10% in one patient (nonresponder (NR)). Before VL, PVI was significantly higher in R than NR at baseline ([19.75 ± 3.15%] vs. [9.7 ± 0.00%], P <0.0001), and decreased significantly in R from baseline to after VL ([19.75% ± 3.15%] vs. [12.5% ± 2.828], P <0.0001). Conclusion In this study, PVI seems to predict fluid responsiveness in ventilated children with ACF.

P184 Collapsibility of jugular veins, subclavian veins and inferior vena cava as predictors of fluid responsiveness in patients on pressure support ventilation: a prospective cohort study

Y Izuka1, M Sanui1, T Nomura2
1. Ichij Medical University Saitama Medical Center, Saitama, Japan; 2. Shonan Kamakura General Hospital, Kamakura, Japan

Introduction The accuracy of predicting fluid responsiveness (FR) using IVC collapsibility is high in patients on controlled mechanical ventilation, but remains unknown in spontaneously breathing patients with mechanical ventilation. Also, adequate ultrasound images of IVC are difficult to obtain in a substantial number of patients. The aim of the current study is to evaluate utility of collapsibility of jugular veins (JV) and subclavian veins (SCV) in comparison with collapsibility of IVC in patients on pressure support ventilation.

Methods Patients on pressure support ventilation were prospectively included when fluid challenges were clinically indicated. Bilateral UV were examined at the level of cricoid cartilage. Bilateral SCV were measured where the veins crossed the clavicle. Anteroposterior diameter, cross-sectional area (CSA) of UV and SCV were measured using frame by frame analysis. IVC was measured 2 cm from the right atrial border in a long axis view. Fluid responsiveness was defined as 8% increase of stroke volume calculated by the Vigileo monitor (Vigileo, FloTrac; Edwards Lifesciences) after passive leg raising (started from supine position). Receiver operating characteristic (ROC) curves were generated using EZR.

Results Twenty-nine patients (35 measurements) were included. Nineteen measurements had fluid responsiveness. The mean tidal
volume was 9.8 ml/predicted body weight. The area under the ROC curve of IVC collapsibility was 0.576 (95% confidence interval (CI): 0.38 to 0.77), while the area under the ROC curves of right UV, left UV, right SCV and left SCV collapsibility were 0.870 (95% CI: 0.74 to 1.0), 0.54 (95% CI: 0.34 to 0.74), 0.62 (95% CI: 0.43 to 0.81) and 0.54 (95% CI: 0.34 to 0.74), respectively. Greater than 11% of right jugular vein collapsibility predicted fluid responsiveness with a sensitivity of 79% and a specificity of 94%.

Conclusion Our results suggest collapsibility of the right jugular vein can be a useful predictor of fluid responsiveness in patients on pressure support ventilation, compared with other central large veins. Collapsibility of IVC does not predict FR in those patients.

P185
Passive leg raising cannot predict volume responsiveness in septic shock patients having cardiac arrhythmia
P Ratanavutkul1, A Wattanathum2
1Srinagarind Hospital, Khan Kaen, Thailand; 2Phramongkutklao Hospital, Bangkok, Thailand

Introduction The passive leg raising test (PLRT) is a self-volume challenge used in order to predict volume responsiveness (VR) in both spontaneous and mechanically ventilated critically ill patients. However, there were small numbers of arrhythmic patients included in previous studies. Therefore, the accuracy of the PLRT for prediction of VR in arrhythmic patient is still inconclusive. We hypothesized that the PLRT can predict VR in mechanically ventilated patients having cardiac arrhythmia.

Methods Mechanically ventilated patients having cardiac arrhythmia who have been considered for volume expansion were recruited in this prospective study. Each patient was sedated, paralyzed and monitored with a central venous catheter and a thermostor-tipped femoral arterial VolumeView catheter connected to the EV1000 monitor. We assessed hemodynamic changes after PLRT via a pulse wave contour analysis method. Then we compared it with hemodynamic changes after volume expansion (NSS 500 ml in 15 minutes) via the transpulmonary thermodilution (TPTD) method.

Results A total of 17 patients were included in this study. Six patients were volume responders (TPTD cardiac index change ≥15%). A PLRT change cardiac index ≥10% from the pulse wave contour analysis method had predicted VR with a sensitivity of 50%, a specificity of 72.7% and an area under the ROC curve of 0.591 (P = 0.546).

Conclusion The PLRT may not be used for prediction of VR in mechanically ventilated patients having cardiac arrhythmia; however, further and larger studies are needed to confirm this finding.

Return on investment for implementation of perioperative goal-directed therapy in major surgery: a nationwide database study
F Michard1, M Krukas1, F Ernst2, S Fogel1
1Edwards Lifesciences, Irvine, CA, USA; 2Premier Inc, Charlotte, NC, USA; 3Carilion Clinic, Roanoke, VA, USA

Introduction Preventable postsurgical complications are increasingly recognized as a major healthcare burden. A recent meta-analysis showed a 17 to 29% decrease in complications after major surgery with perioperative goal-directed therapy (PGDT) [1]. We assessed the financial consequences of postsurgical complications in a large population from 541 US hospitals in order to predict potential savings with PGDT.

Methods Data from adults who had any one of 10 major noncardiac surgical procedures between January 2011 and June 2013 were selected from the Premier research database. Twenty-six postsurgical complications were tabulated. Hospital costs, length of stay, and readmission rates were compared in patients with and without complications. Risk ratios reported by Pearse's meta-analysis were used to estimate the expected reduction in postsurgical morbidity with PGDT. Potential cost-savings were calculated from the actual and anticipated morbidity rates using the mean difference in total costs.

Results A total of 204,680 patients met the search criteria, and 76,807 patients developed one or more postsurgical complications (morbidity rate 37.5%). In patients with and without complications, hospital costs (including 30 days readmission costs) were $27,607 ± 32,788 and $15,783 ± 12,282 (P < 0.0001), median (interquartile range) hospital lengths of stay (first stay) were 7 (4 to 10) days and 4 (3 to 5) days (P < 0.0001), and 30-day readmission rates were 17.2% and 11.9% (P < 0.0001), respectively. With PGDT, the morbidity rate was anticipated to decrease from 26.6 to 31.1%, yielding gross cost savings of $153 million to 263 million for the study period, $61 million to 105 million per year, or $754 to 1,286 per patient. These projections should help hospitals estimate the return on investment for implementation of PGDT.

Figure 1 (abstract P187). ROC curve for VPW discriminating fluid repletion by IVC ultrasound.
Conclusion A VPW value of 64 mm accurately identifies a fluid replete state. Increased extravascular lung water, however, was not relatable to the VPW measurements. The VPW can be confidently used to discriminate fluid repletion from fluid responsiveness.

P188
Bioimpedance as a measure of fluid overload in patients recently admitted to intensive care
M O’Connor, E Galtrey, CJ Kirwan, JR Prowle
Barts Health NHS Trust, London, UK

Introduction Fluid overload is associated with adverse outcomes in critical illness; however, better methodology is required for its quantification. Bioelectrical impedance analysis (BIA) represents a non-invasive method for quantification of fluid overload [1], but has not been widely taken up in the ICU.

Methods We assessed changes in fluid balance and performed daily BIA (using a Maltron Biocom 920-II; Maltron International Ltd, UK) over 3 days in consecutive ICU admissions with LOS >72 hours.

Results Of 24 patients 71% were male, median age was 65 years and APACHE II score was 15. Eleven patients had a medical diagnosis and 13 a surgical or trauma reason for admission. Seventy-one percent were mechanically ventilated and 67% were on vasopressors or inotropes. Median BIA-estimated extracellular water was 25.2 l (IQR 22 to 28) on day 1, equating to excess fluid of 7.2 l (IQR 5 to 13.9). Median right body resistance normalized to height at 50 kHz (R50/h) on day 1 was 214 Ω/m (IQR 187 to 256). Daily change in ECW and R50/h correlated with daily fluid balance between BIA measurements (R² = 0.48 and 0.37 respectively) (Figure 1).

Conclusion BIA suggests many patients already have significant fluid overload on the first day of ICU admission. Overall, changes in device-specific algorithms for ECW estimation and measured resistances correlated with recorded fluid balance; however, there were inconsistencies in the number of individual patients. Prospective assessment is required to establish whether BIA measurements can be used to assist fluid management in the ICU.

P189
Minimal volume for a fluid challenge in postoperative patients
H Aya, A Rhodes, RM Grounds, M Cecconi
St George’s Healthcare NHS Trust, London, UK

Introduction An effective fluid challenge should increase the mean systemic filling pressure (Pmsf) in order to increase the venous return. The objective of this study was to determine the minimum volume of intravenous fluid required to significantly increase the Pmsf.

Methods Patients following cardiac surgery were randomly allocated to receive 1, 2, 3 or 4 ml/kg (body weight) of crystalloid over 5 minutes using a 60 ml syringe. Pmsf was measured using the arterial pressure after stopping blood flow in the arm with a pneumatic tourniquet inflated for 1 minute. Cardiac output (CO) was also recorded at baseline and immediately after the fluid infusion. CO was measured with LiDCO or pulmonary artery catheter, and a positive response was considered an increase of 10% from baseline. From previous data, the least significant change for Pmsf was 15%. Medians were compared using the independent samples media test, and proportions were compared using a chi-square test. Statistical significance was considered when P <0.05.

Results Fifty patients were included, 40.8% of them were responders. The proportion of responders increases with the increase of dose of fluids (Table 1). The regression equation was change of Pmsf (%) = 4.4 (dose of fluids ml/kg, 95% CI 2.3 to 6.5) – 1.6 (95% CI 7.4 to 4.3, R² = 0.28, F(1,47) = 17.8, P <0.001). The predicted dose of fluids required to achieve a change in Pmsf of 15% is 3.7 ml/kg crystalloids.

Table 1 (abstract P189). Change of Pmsf-arm and CO

</tbody>
</table>

Values are median (interquartile range).

Conclusion The minimum volume required to perform an effective fluid challenge is 4 ml/kg infused in 5 minutes. However, only 30% of the variation of change in Pmsf can be explained by the dose of i.v. fluid given. The proportion of responders increases with the volume of fluids.

P190
Positive fluid balance is an independent risk factor for acute kidney injury in critically ill patients: results of a prospective, cross-sectional study
N Salahuddin, M Sammani, A Hamdan, M Joseph, Y AlNemary, R Alquaiz, K Maghrabi
King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Introduction In critical illness, fluid overload may predispose to acute renal dysfunction by a number of mechanisms. Once acute kidney
injury (AKI) develops, positive fluid balance has been described as a risk factor for overall mortality and delayed renal recovery. We hypothesized that fluid overload may be an independent risk factor for AKI in the critically ill.

Methods In a cross-sectional design, we collected data on consecutive, critically ill, adult patients admitted over a 5-month period to the medical and surgical ICUs of a single center. AKI was defined according to the RIFLE Classification. Logistic regression analysis was performed to determine the predictive ability of variables for AKI. The institutional Research Ethics Committee approved the study.

Results Three hundred and thirty-nine patients were included; mean age was 51 ± 20.4 years, 167 (49%) patients were male. Mean APACHE II score was 22 ± 12.8 and SAPS II score was 35.4 ± 18.9. Severe sepsis/septic shock was the admitting diagnosis in 129 (38%) patients, 108 (32%) patients were postoperative. AKI developed in 148 (44%) patients; Risk 29 (9%); Injury 26 (8%); Failure 89 (26%) by the RIFLE criteria. On univariate regression analysis; positive fluid balance >2 l on the first ICU admission day, OR 2 (95% CI = 1.3, 3.3, P = 0.002); age, OR 2.7 (95% CI = 1.7, 4.2, P = 0.000); CHF, OR 3.1 (95% CI = 1.2, 7.9, P = 0.013); APACHE II score, OR 1.02 (95% CI = 1.01, 1.04, P = 0.006); SAPS II score, OR 1.04 (95% CI = 1.02, 1.05, P = 0.00); mean MAP on admission, OR 0.98 (95% CI = 0.96, 0.99, P = 0.033); need for vasopressors on admission, OR 2.7 (95% CI = 1.7, 4.2, P = 0.0001) and for ≥24 h, OR 2.7 (95% CI = 1.7, 2.5, P = 0.001) and vancomycin use, OR 1.5 (95% CI = 1.02, 2.53, P = 0.04) significantly predicted the development of AKI. On multivariate regression, CHF, OR 3.8 (95% CI = 1.4, 10, P = 0.007); age, OR 1.02 (95% CI = 1.01, 1.03, P = 0.001); vasopressors for >24 h, OR 2.6 (95% CI = 1.6, 4.2, P < 0.001) and a >2 l positive fluid balance on the first ICU day, OR 1.6 (95% CI = 1.02, 2.7, P = 0.04) remained significant predictors.

Conclusion Fluid overload, defined as a >2 l positive fluid balance on the first day of ICU admission, is an independent risk factor for the development of AKI in the general ICU population.

P191 Positive fluid balance as a risk factor for mortality and acute kidney injury in vasoplastic shock after cardiac surgery
A Rezende1, L Camara2, A Leme3, J Ribeiro1, I Bispo2, S Zeferrino2, J Jardim1, C Park1, E Osawa2, J Almeida2, A Gerent1, F Galas2, D Fonseca2, J Fukushima1, L Hajjar2
1ICESP, São Paulo, Brazil; 2Heart Institute, University of São Paulo, Brazil

Introduction After cardiac surgery, about 15% of patients develop vasoplastic shock, characterized by systemic vasodilation, increased capillary permeability and edema. We hypothesized that large-volume resuscitation, resulting in positive fluid balances in the first 24 hours of ICU admission, would be associated with mortality and would not be protective against AKI in this subset of patients.

Methods This is a retrospective analysis of 362 patients submitted to cardiac surgery at the Heart Institute of University of São Paulo in a period of 2 years. Of a total of 2,383 patients, we enrolled 362 patients. Vasoplastic shock was diagnosed if in the 24 hours of ICU admission patients had hypotenension, need of vasoactive drugs after fluid replacement and cardiac index <2.2 L/min/m². Data were analyzed in logistic regression models for 30-day mortality and acute kidney injury through Acute Kidney Injury Network (AKIN) score as outcomes.

Results The mean age of patients was 57 years. Of 362 patients, 53 died at 30 days (14.6%). Nonsurvivors as compared with survivors were slightly older (59 ± 12 vs. 55 ± 13, P = 0.063), had a higher prevalence of AKI through AKIN score (6 vs. 4.9%, 11.1%, 2.89%, 31.9%, P < 0.001), a higher 24-hour fluid balance (421 ml (≤55 to 695) vs. 2,686 ml (1,321 to 2,856), P < 0.001), and higher lactate levels at the intraoperative and at 48 hours (5 mmol/L (4.0 to 7.6) vs. 4.4 (3.3 to 6.55), P < 0.001; and 8.11 (5.49 to 12.3) vs. 1.5 (1.33 to 1.88), P < 0.001). In the multivariate analysis, positive fluid balance in the first 24 hours (OR = 1.006, 95% CI = 1.001 to 1.002, P = 0.001) and higher lactate at 48 hours (OR = 1.011, 95% CI = 1.00 to 1.021, P = 0.0043) were predictors of 30-day AKI.

Conclusion Positive fluid balance after cardiac surgery is an independent risk factor for mortality and for acute kidney injury in patients presenting vasoplastic shock.

P192 Impact of postsurgical complications on hospital costs and margins
R Lavender1, M Mythen2, J Bao1, RH Chapman3, F Michard1
1Edwards Lifesciences, Irvine, CA, USA; 2UCLH National Institute of Health Research, London, UK; 3Avalere Health, Washington, DC, USA

Introduction The impact of postsurgical complications (PSC) on hospital cost has been studied but the impact on margins remains controversial [1]. We assessed economic consequences of PSC in US Medicare patients, and benefits expected from reducing PSC by 14% to 40% with Enhanced Recovery Programs [2].

Methods Data from patients with ≥1 comorbidity and major cardiac, vascular, gastrointestinal and orthopedic surgeries in 2011 were extracted from Medicare Standard Analytic Files. Hospital margin was calculated as payment minus cost. Patients with and without PSC were compared, and the economic impact of a 14 to 40% relative reduction in PSC was calculated.

Results Of 303,432 patients, 37% had ≥1 PSC. Median length of stay was 10 days for patients with ≥1 PSC and 6 days without (P < 0.0001 with vs. without PSC), with readmissions for 21% and 16%, respectively (P < 0.0001 with vs. without PSC). Average margins for cases with PSC converted into without PSC would be $1,870 higher. A 14 to 40% reduction in patients with PSC (from 37% to 32% to 22%) would result in saving $153 million to $438 million, and increase hospital margins overall by $28 million to $79 million. See Table 1.

P193 Lactate levels after major cardiac surgery are associated with hospital length of stay
LW Andersen, M-Holmberg, P Patel, KM Berg, M Cocchi, M Doherty, K Khazzab, MW Domnino
Beth Israel Deaconess Medical Center, Boston, MA, USA

Critical Care 2015, Volume 19 Suppl 1
http://ccforum.com/supplements/19/S1

Introduction The objective of the study was to evaluate whether postoperative lactate values are associated with hospital length of stay in patients undergoing major cardiac surgery. Previous studies have shown an association between postoperative lactate levels and increased morbidity and mortality after major cardiac surgery. However, the association between lactate and hospital length of stay has not been adequately characterized.

Methods We performed a retrospective analysis of all patients presenting for coronary artery bypass grafting and/or valve surgery between 2002 and 2014 at a tertiary care center in Boston, who had a lactate level measured within 3 hours of skin closure. Lactate values
were categorized into clinical meaningful categories: 0 to 2 mmol/l (normal), 2 to 4 mmol/l (elevated) and ≥4 mmol/l (high) to allow for nonlinear effects. The unadjusted association between lactate group and length of stay was assessed with the Kruskal–Wallis test and post hoc Wilcoxon rank-sum tests. To assess the association between postoperative lactate levels and hospital length of stay we performed multivariable Poisson regression with robust variance estimates. We adjusted for more than 30 variables including patient demographics, comorbidities, cardiac characteristics (for example, New York Heart Association class and ejection fraction), and surgical characteristics (for example, year, status (elective, urgent, emergent), type of procedure, perfusion time, and cross clamp time).

Results We included a total of 1,267 patients. The median age was 68 (quartiles: 59, 76), 32% were female, 68% underwent coronary artery bypass grafting and 59% underwent valve surgery. Median length of hospital stay was 6 days (quartiles: 5, 9). Median length of stay in the normal, elevated and high lactate groups were 5 days (quartiles: 4, 7), 6 days (quartiles: 5, 9) and 9 days (quartiles: 6, 17), P < 0.001 for comparison. In multivariable analysis, patients with an elevated lactate had a 1.12 times (95% CI: 1.02 to 1.23, P = 0.02) longer length of stay compared with those with normal lactate. Patients with a high lactate had a 1.30 times (95% CI: 1.10 to 1.53, P = 0.002) longer length of stay compared with those with normal lactate.

Conclusion Postoperative lactate levels are associated with increased length of hospital stay in patients undergoing major cardiac surgery. Interventions aimed at decreasing postoperative lactate levels may decrease hospital length of stay.

P194 Hemodynamic behavior in a randomized trial of intensive alveolar recruitment after cardiac surgery
A Leme, M Amato, E Osawa, J Fukushima, M Feltrin, E Nozawa, J Almeida, L Hajar, F Galas
Heart Institute, São Paulo, Brazil

Introduction The potential benefits of a protocol of intensive alveolar recruitment may be outweighed by its detrimental effects in hemodynamic stability after cardiac surgery. The aim of this study was to analyze the hemodynamic behavior of patients included in a trial of intensive alveolar recruitment after cardiac surgery.

Methods In this randomized trial, we assigned adult patients with PaO₂/FIO₂ < 250 at a PEEP of 5 cmH₂O to either intensive alveolar recruitment or a standard protocol, both using low-tidal volume ventilation (6 ml/kg/lbw) after adequate volemia status. Our hypothesis was that an intensive alveolar recruitment protocol with controlled pressure of 12 cmH₂O and PEEP of 30 cmH₂O during 1 minute, repeated three times at 1-minute intervals between each maneuver, would not cause hemodynamic instability.

Results In total, 163 patients were included in the standard and 157 in the intensive group. Patients of the intensive group had a significant reduction of the MAP at T1, T2 and T3 (1 hour, 2 hours and 3 hours of the protocol), returning to baseline after T4 (Figure 1). No patients had severe hypotension (MAP < 65 mmHg) and the study was not stopped in any case. The length of the hospital stay was shorter among patients in the intensive group (10.9 (9.9 to 11.9) vs. 12.4 days (11.3 to 13.6); P = 0.045).

Conclusion An intensive alveolar recruitment protocol did not result in hemodynamic instability in hypoxemic patients after cardiac surgery (NCT01502332).

P195 Team-based extubation protocol in cardiac surgical patients reduces ventilation time and reduces length of stay in the ICU
JIM Taculud, MJ Dajac, A Del Rosario, J Gammad, S Mahaju, O Siow Eng, P Oh, R Kollengode, G Maclaren, ME Cove
National University Hospital, Singapore

Introduction National University Hospital, Singapore, recently formed a Division of Critical Care – Respiratory Therapy. This service rapidly expanded to provide 24/7 Respiratory Therapy Services in the cardiothoracic intensive care unit (CTICU). One goal of service expansion was a reduction in duration of mechanical ventilation after cardiac surgery. We hypothesized that introduction of a team-based extubation protocol would reduce the duration of mechanical ventilation and ultimately affect ICU length of stay.

Methods A multidisciplinary group created a team-based extubation protocol. The protocol was applied to all elective postoperative cardiac surgery patients. To assess the protocol’s impact, data were collected in a registry 3 months before and 3 months after protocol initiation. Data collection included cardiopulmonary bypass time, McCormack airway assessment, ICU admission time, initial pH, lactate, inotropes upon arrival at the CTICU, blood gas analysis prior to extubation, time of extubation and length of stay. Patients were excluded from data analysis if they experienced events which contraindicated application of the protocol, such as significant intraoperative or postoperative complications. These events were explicitly stated in the extubation protocol. Singapore’s Domain-specific review board granted waiver of patient consent to analyze and present these data.

Results A total of 201 patients undergoing elective open cardiac surgery were included; 99 patients before protocol implementation (pre-protocol) and 102 patients after implementation (post-protocol). There was no significant difference in mean age (60 vs. 61 P = 0.823), gender (79.8% vs. 79.4% P = 1.00), EuroSCORE (26 vs. 32 P = 0.576) and proportion receiving bypass surgery (72% vs. 80% P = 0.206) or valve surgery (21% vs. 19% P = 0.722) between the two groups. Median extubation time was reduced by 3.5 hours (620 minutes vs. 408 minutes P < 0.001). ICU length of stay was also reduced following introduction of the protocol: 48 hours versus 24 hours post protocol (P < 0.001).

Conclusion A team-based extubation protocol significantly reduced the duration of mechanical ventilation and this translated to reduced ICU length of stay in patients undergoing elective open-heart surgery.

P196 Impact of patient frailty on outcome in cardiothoracic surgery
J Brohan, P Delaney, B O’Brien
Cork University Hospital, Cork, Ireland

Introduction Frailty is defined as a multidimensional syndrome involving loss of physical and cognitive reserve leading to greater vulnerability to adverse events [1]. Such events include susceptibility to unplanned hospital admissions, and death [1-3]. Frailty is associated with increased ICU and 6-month mortality, and reduced quality of life [4]. The aim of this study is to investigate the impact of baseline frailty on postoperative quality of life indicators and postoperative frailty following cardiothoracic surgery.

Methods Adult patients undergoing cardiac surgery or thoracic surgery (involving thoracotomy) were included in this study. Baseline measures of frailty [4] and performance status were prospectively recorded using validated tools. Informed consent was obtained prior to inclusion. Outcome measures of APACHE II scores, duration of ventilation, length of postoperative stay, complications, and hospital readmission were recorded for 6 months after discharge. Multivariable analysis was performed using logistic regression to assess the impact of patient frailty on outcome measures.
of ICU stay and mortality were recorded. Follow-up at 6 months was conducted by telephone to assess recovery patterns.

Results A total of 120 patients were included in this study, including 100 patients who underwent cardiac surgery and 20 patients who underwent thoracic surgery. Eighty-five patients (70.8%) were male. The mean age was 65.4 years (range 25 to 89 years). The mean baseline frailty score also varied widely within our cohort. Four patients died in the ICU following their surgery (3% ICU mortality rate). Mean length of ICU stay was 2.7 days (range 0 to 20 days), with a mean duration of ventilation time of 20 hours (range 0 to 264 hours). Follow-up of these patients at 6 months following their surgery is currently underway.

Conclusion Owing to advances in life expectancy, health and perioperative medicine, it has become more difficult to determine fitness for major surgery. Our data suggest that frailty may be a useful prognostic measure to help inform such decisions.

P197 Preoperative intra-aortic balloon counterpulsation in cardiac surgery: propensity analysis of data obtained from the ARIAM Registry of Cardiac Surgery
MD Delgado-Amaya, C Joya-Montosa, J Muñoz-Bono, E Curiel-Balsera
Hospital Regional de Málaga, Spain

Introduction The aim of our study was to assess whether the preoperative use of IABP is beneficial in patients undergoing cardiac surgery of any kind.

Methods An observational, retrospective, multicenter study of all patients undergoing cardiac surgery and included in the ARIAM-ANDALUCIA Registry of Cardiac Surgery from March 2008 to July 2012. The probability of placing IABP in the preoperative period has been calculated, making a propensity analysis to obtain two homogeneous groups treated with or without the IABP, based on personal history, functional status and type of surgery. Seventy-seven patients with preoperative IABP were matched with 77 patients without BCIAO with the nearest propensity score. We used the chi-square test or Student t test as needed, establishing the level of statistical significance at 95%.

Results Of the 8,026 patients who underwent cardiac surgery during the study period, BCIAO was implemented in 358 (4.5%) of them. In total, 65.4% were male. Surgical times in those patients where IABP was implanted were 146 ± 81 minutes and 90 ± 66 minutes (cardiopulmonary and aortic clamping times, respectively). The in-surgery room mortality was 4.7%, 30-day mortality in these patients was 40.2%. Patients in whom IABP was implanted had a mortality rate eight times higher than those who did not require it during surgery or postoperatively (40.2% vs. 8.4%, P = 0.0001. OR 8.1, 95% CI (6.4 to 10.3)). Besides mortality was higher, the later IABP was implanted the higher the mortality rate was (29.6% of the preoperative, 44.2% of surgical and 54.4% of those starting in ICU, P = 0.015). The ICU length of stay was 9 ± 22 days while the hospital length of stay was 21 ± 28 days. In patients who needed IABP, the ICU stay was higher than for those who did not need it (9 ± 22 vs. 5 ± 10 days, P = 0.002) whereas there was no difference in hospital stay (21 ± 28 vs. 20 ± 24 days, P = 0.054).

Conclusion The intra-aortic balloon pump was used by 4.5% of surgeries performed during the study period and in patients with an increased risk of perioperative complications, estimated by EuroSCORE, ICU length of stay was higher in patients requiring IABP, with no differences in overall hospital stay. Mortality rate was 40% higher, and increases with the delay in the implantation.

P198 Intraaortic balloon pump use in cardiac surgery: analysis of data from the ARIAM Registry of Cardiac Surgery
J Muñoz-Bono, MD Delgado-Amaya, E Curiel-Balsera, C Joya-Montosa, G Quesada-García
Hospital Regional de Málaga, Spain

Introduction The aim of the study is to analyze IABP use in patients undergoing cardiac surgery included in the ARIAM Registry of Cardiac Surgery.

Methods An observational, retrospective, multicenter study of all patients undergoing cardiac surgery included in the ARIAM-ANDALUCIA database of Cardiac Surgery from March 2008 to July 2012. We used the chi-square test and Student t test as needed, establishing the level of statistical significance at 95%.

Results Of the 8,026 patients who underwent cardiac surgery during the study period, BCIAO was implanted in 358 (4.5%) of them. In total, 65.4% were male. Surgical times in those patients where IABP was implanted were 146 ± 81 minutes and 90 ± 66 minutes (cardiopulmonary and aortic clamping times, respectively). The in-surgery room mortality was 4.7%, 30-day mortality in these patients was 40.2%. Patients in whom IABP was implanted had a mortality rate eight times higher than those who did not require it during surgery or postoperatively (40.2% vs. 8.4%, P = 0.0001. OR 8.1, 95% CI (6.4 to 10.3)). Besides mortality was higher, the later IABP was implanted the higher the mortality rate was (29.6% of the preoperative, 44.2% of surgical and 54.4% of those starting in ICU, P = 0.015). The ICU length of stay was 9 ± 22 days while the hospital length of stay was 21 ± 28 days. In patients who needed IABP, the ICU stay was higher than for those who did not need it (9 ± 22 vs. 5 ± 10 days, P = 0.002) whereas there was no difference in hospital stay (21 ± 28 vs. 20 ± 24 days, P = 0.054).

Conclusion The intra-aortic balloon pump was used by 4.5% of surgeries performed during the study period and in patients with an increased risk of perioperative complications, estimated by EuroSCORE, ICU length of stay was higher in patients requiring IABP, with no differences in overall hospital stay. Mortality rate was 40% higher, and increases with the delay in the implantation.

P199 Vasopuglic syndrome in cardiac surgery: role of synergism between polymorphism of tumor necrosis factor beta and plasminogen activator inhibitor type 1
JL Iribarren, J Jiménez, N Perez, M Brouad, R Perez, E Hurtado, S Diosdado, M Buitrago, A Arbesu, R Martinez, M Mora
Hospital Universitario de Canarias, La Laguna, Spain

Introduction Cardiopulmonary bypass can lead to postoperative hemodynamic disorders. Several genetic polymorphisms have been studied in this setting. We investigated the possible existence of a synergism between polymorphisms of plasminogen activator inhibitor type 1 (PAI-1) and tumoral necrosis factor beta (TNF-β) on hemodynamic response after cardiac surgery.

Methods We prospectively studied the association between hemodynamic response and polymorphisms of TNF-B and PAI-1 in 563 patients undergoing elective cardiac surgery during the years 2008 to 2011. We tested the Hardy–Weinberg equilibrium in the sample. V18 SPSS was used.

Results We studied 563 patients. We found significant differences in TNF-8 polymorphisms regarding norepinephrine requirements at 4 hours (F: 15.9; P < 0.001), post hoc Scheffé (GG vs. AA, 0.32 (0.11 to 0.65) vs. 0.06 (0.04 to 0.09) µg/kg/minute, P < 0.001; GG vs. AG, 0.32 (0.11 to 0.65) vs. 0.06 (0.03 to 0.08), P < 0.001) and at 24 hours (F: 8; P = 0.005), post hoc Scheffé (GG vs. AA, 0.27 (0.01 to 0.52) vs. 0.10 (0.06 to 0.14), P = 0.019; GG vs. AG, 0.27 (0.01 to 0.52) vs. 0.07 (0.04 to 0.09), P = 0.003). Unfavorable TNF-B (G homozygous vs. allele A) and PAI-1 unfavorable (4G homozygous vs. allele 5G) were grouped, after adjusting for perioperative significant variables. The unfavorable GG and 4G alleles were significant for NA 4 hours (F: 5.5; P = 0.02 and F: 4.1; P = 0.04, respectively) and GG–4G allele interaction (F: 6; P = 0.01) (Figure 1).
while for NA at 24 hours statistics showed GG (F: 3.2; P = 0.07), 4G allele (F: 2; P = 0.15) and interaction (F: 3.6, P = 0.05).

Conclusion GG homozygous polymorphism TNF-B is associated with an increased dependence on norepinephrine after cardiopulmonary bypass, showing a synergistic action with the 4G allele of PAI-1.

Pharyngeal oxygenation during apnoea following conventional pre-oxygenation and high-flow nasal oxygenation
D Stolady, M Maniyaselvam, H Young, E Fawzy, M Blunt, P Young
Queen Elizabeth Hospital, King’s Lynn, UK

Introduction We hypothesised that pharyngeal oxygen concentrations would be maintained higher and for longer with transnasal humidified rapid insufflation ventilatory exchange (THRIVE) than conventional bag-mask pre-oxygenation (CPO). CPO requires the mask to be removed during laryngoscopy; this means that air may enter the mouth so subsequent apnoeic oxygenation will be less effective. Oral suctioning could exacerbate this process. However, if high pharyngeal oxygen concentrations and an open airway are maintained, apnoeic oxygenation could be substantially improved. Methods used have included NO-DESAT [1] and recently THRIVE [2], which has been shown to extend apnoea times for up to 1 hour.

Methods A volunteer with a nasopharyngeal sampling catheter underwent simulated emergency airway management (EAM), using both CPO and THRIVE, with and without suction. Following 3 minutes of pre-oxygenation with CPO (FiO2 = 1, FEKO >0.8) or THRIVE (60 l/minute; Optiflow, Fisher & Paykel), EAM was simulated by voluntary apnoea and pharyngoscopy with the laryngoscope blade tip placed 2 cm from the posterior pharyngeal wall. Capnography at the laryngoscope tip confirmed apnoea. Pharyngeal gas samples (20 ml) were collected during apnoea, and after 5 seconds of oropharyngeal suctioning. Pre-oxygenation was repeated between sampling. Samples (n = 100) were analysed using calibrated fuel cells.

Results Pharyngeal oxygen concentrations (mean and SEM) are shown in Figure 1 (all points are significant P <0.05).

Conclusion Pharyngeal oxygen concentration rapidly falls following CPO. This may be detrimental for apnoeic oxygenation during conventional laryngoscopy. Conversely, THRIVE maintains high pharyngeal oxygen concentrations over time. Suction has an immediate negative effect on pharyngeal oxygen concentration that is attenuated by THRIVE. Assessment of NO-DESAT (15 l/minute) was abandoned due to discomfort.

Effects of high-flow nasal cannula therapy on oxygenation, lung volumes and CO2 removal in critically ill hypoxemic patients: preliminary results
T Mauri, N Eronia, G Bellani, G Grasselli, R Marcocci, S Marocco Arrigoni, A Pesenti
1RCC Ca’ Granda Maggiore PoliChirico Hospital, Milan, Italy; 2San Gerardo Hospital, Monza, Italy

Introduction High-flow nasal cannula (HFNC) is increasingly proposed as respiratory support for hypoxemic non-intubated acute respiratory failure patients. Clinically, HFNC therapy decreases dyspnea, improves patient’s comfort, improves oxygenation and enhances clearance of upper airway secretions [1]. We present preliminary results from a clinical study aimed at measuring the effects of HFNC on gas exchange, lung volumes and inspiratory effort in hypoxemic non-intubated critically ill patients.

Methods We performed a prospective randomized cross-over study on hypoxemic non-intubated patients (PaO2/FiO2 <300 mmHg) admitted to the ICU of the San Gerardo Hospital and prescribed to receive oxygen by facial mask. We delivered the same air/oxygen mix by HFNC (Optiflow; Fisher & Paykel Healthcare, Auckland, New Zealand) and facial mask (20 minutes per step). Continuous recordings of regional lung volumes by EIT (Pulmovista 500; Drager Medical GmbH, Lubeck, Germany) and of inspiratory effort by esophageal pressure (Pes) were obtained and analyzed offline by dedicated software.

Results We enrolled 15 patients (10 male), age 57 ± 16 years. Compared with standard facial mask, HFNC significantly improved PaO2/FiO2 (199 ± 60 vs. 150 ± 46, P <0.001) and end-expiratory lung impedance (corresponding to aeration) (866 ± 568 au vs. baseline, P <0.001). Moreover, HFNC decreased the respiratory rate (22 ± 5 bpm vs. 20 ± 5 bpm, P <0.001), as well as negative Pes swings (ΔPes 8.3 ± 5 mmHg vs. 6.6 ± 1 mmHg, P <0.01) and corrected minute ventilation (that is, actual MV × actual PaCO2 / 40 mmHg) (49,887 ± 16,176 au vs. 41,811 ± 14,042 au, P <0.001). Finally, central venous pressure increased (6 ± 5 mmHg vs. 4 ± 5 mmHg, P <0.01), possibly indicating positive end-expiratory pressure effect.

Conclusion In non-intubated hypoxemic critically ill patients, HFNC improves oxygenation and end-expiratory aeration; moreover, HFNC reduces the inspiratory effort and the minute ventilation needed to maintain normal arterial CO2 tension.

New assembled video laryngoscope: a study on efficacy and cost-effectiveness
SM Ayyan, Z Ali
Pariyaram Medical College, Kannur, Kerala, India

Introduction Video laryngoscopes have been introduced in recent years as an alternative choice to facilitate tracheal intubation. Difficulties with tracheal intubation are mostly caused by difficult direct laryngoscopy with impaired view to the vocal cords. Many endoscopic intubation laryngoscopes have been designed to visualize the vocal cords around the corner looking through a proximal viewfinder. Although they are useful devices, they have limitations for doing direct laryngoscopy and are very expensive, hence they are not used for routine tracheal intubation.

Methods A Macintosh intubating laryngoscope has been modified by attaching a waterproof USB camera with an inbuilt light source, which
is located in the same position as the light source on the standard Macintosh blade thus providing a view angle of up to 290° and the USB camera is connected to a laptop. A total of the first 50 patients who presented to the emergency department over a period of 6 months in need of intubation were included in the study and every alternate patient participated in the evaluation of the assembled video laryngoscope (VAL). Information about patient demographics and airway characteristics, Cormack-Lehane (C/L) views and the ease of intubation using the VAL was collected. Failure was defined as more than one attempt at intubation.

**Results** Excellent (C/L1) or good (C/L2) laryngeal exposure was obtained in 92% and 8% of patients respectively. In 25 patients in whom VAL was performed, there was a comparable or superior view. Intubation with direct laryngoscopy was successful in 95.2% of patients and VAL was successful in 95.4% of patients. Three patients from the VAL group and four patients from the direct laryngoscopy group were excluded. See Figure 1.

**Conclusion** This new assembled VAL is the cheapest video-assisted laryngoscope available costing around $60, which can even be introduced into primary healthcare setup in developing countries. VAL consistently yielded a comparable or superior glottic view compared with direct laryngoscopy despite the limited or lack of prior experience with the device. Because the device can be used for both routine as well difficult tracheal intubation, it may be a helpful tool to intubate trauma cases where C-spine immobilization is unavoidable. The presented video-assisted laryngoscope is a useful tool for documentation, teaching and monitoring tracheal intubation.

**Availability of appropriate airway monitoring at UK in-hospital cardiac arrest**

S Turle1, PB Sherrers1, T Callaghan1, S Nicholson1, SJ Shepherd1

1Pan-Thames Intensive Care Training Scheme, London, UK; 2KSS Intensive Care Training Scheme, London, UK

**Introduction**

Airway complications are more common outside the operating theatre and in emergency situations. Capnography remains the gold standard of confirming correct endotracheal tube (ETT) placement, retaining high sensitivity and specificity in cardiac arrest [1]. The 2010 European Resuscitation Council guidelines for adult advanced life support recommended waveform capnography in this setting [2]. Failure to use capnography was also identified as a major contributor to airway-related morbidity and mortality in a national UK audit [3]. We sought to investigate current practice relating to the availability and use of capnography equipment cardiac arrest within UK hospitals.

**Methods**

Between June and November 2014, a telephone survey was conducted of all UK acute hospitals with adult level 3 ICUs and an emergency department (ED). Hospitals were identified using nationally available data. A standardised telephone questionnaire was developed examining practice regarding intubation for cardiac arrest and the availability and utilisation of capnography within the ED, ICU and general wards. Questions were directed at the anaesthetist or intensive care doctor ‘responding to cardiac arrest calls’. The respondent was given the option to decline participation. All data were anonymised.

**Results**

A total of 211 hospitals met the inclusion criteria. The response rate was 100%. Arrest calls were mainly attended by anaesthesia (47.8%) and ICU doctors (38.3%) with around 2% physicians only. Most were a registrar grade (56.3%). The ability to measure ETCO2 was available in all but four EDs; most used waveform capnography. A similar pattern was seen in the vast majority of ICUs: a single institution reported no capnography available. However, in 141 (66.8%) of the hospitals surveyed, no facility to measure ETCO2 was present on the general wards. Where available, 86.7% used capnography to confirm ETT placement. Less than 50% used ETCO2 to determine CPR effectiveness and 8% to prognosticate.

**Conclusion**

We believe this is the first study of its kind to follow NAP4 and investigate the availability of capnography throughout for use during cardiac arrest. Whilst equipment levels appear adequate (albeit not perfect) in resuscitation areas, there appears a lack of availability of suitable devices on general wards.

**Using a laryngoscope and endotracheal tube succeeds in a difficult case of nasogastric tube insertion**

J Park, Y Lee

Ewha Womans University Hospital, Seoul, South Korea

**Introduction**

Nasogastric (NG) tube insertion is necessary in a variety of critically ill patients for intra-abdominal decompression, prevention of aspiration, route of medication administration and nutrition. However, it often fails in patients who showed sedated or comatose mentality with poor cooperation during the procedure. Although there are many reports inserting a NG tube in difficult cases, most methods need a special guide wire, tube or nasoendoscope. We report a case of NG tube insertion in a comatose patient using a laryngoscope and endotracheal tube which are easily available.

**Figure 1 (abstract P204).** Insertion of a nasogastric tube through an endotracheal tube in the esophagus.
Methods A NG tube was inserted using a laryngoscope and endotracheal tube.

Results A 15-year-old male patient admitted due to abrupt mental change and brain imaging showed severe subdural hemorrhage. NG tube insertion was done for enteral feeding but failed several times though changing position. As we had no guide wire and no nasoendoscope, an endotracheal tube was used as guidance for the NG tube. After making a longitudinal midline cut on the endotracheal tube, it was inserted into the esophagus under a laryngoscope. The NG tube was pushed into the endotracheal tube, and then the endotracheal tube was removed through the cut, reserving the NG tube. We checked the position of the NG tube by air sound and X-ray, and started enteral feeding without complication, such as nasal bleeding, emphysema, and gastric perforation. See Figure 1.

Conclusion We report a new method of NG tube insertion using a laryngoscope and endotracheal tube.

P205 Admissions with airway emergencies in the ICU at a tertiary referral centre
M Gresoiu, M Singer
University College London Hospital, London, UK

Introduction As a tertiary referral centre for ENT and maxillo-facial surgery, our ICU receives complex elective and emergency cases. The frequency, aetiology and outcomes of airway emergencies are poorly described. Understanding these factors is key to improving management.

Methods We conducted a retrospective review of the ICU electronic patient database examining unplanned admissions with airway emergencies between December 13 and November 14. Data on demographics, aetiology of airway obstruction (including postprocedural), APACHE II score, therapeutic intervention(s) administered, and outcomes were collected.

Results Of 1,516 unplanned admissions, airway emergencies represented 63.3% (96 patients) of whom 40 (41.7%) had malignancy (26 maxillo-facial/trachea, three pulmonary, four haematological, seven other) and 24 infection (abscesses, epiglottitis, Ludwig’s angina). Referring specialties were maxillo-facial surgery (n = 34), internal medicine (n = 25), ENT (n = 21) and other surgical specialties (n = 16). Thirteen patients had complications post bronchoscopy (vocal cord paralysis, need for NIV or intubation), one post microlaryngoscopy, and 20 were admitted after difficult intubation. Eighteen were admitted post drainage of abscess (dental, retropharyngeal) and seven for observation for epiglottitis. Thirteen patients had stridor (three tracheal stenosis, one vocal cord cyst, one post CVA, four post vocal cord palsy, one post oesophageogaphy, one post thyroidectomy, two post decannulation). Seven were admitted after emergency tracheostomy, one after blocked tracheostomy, one after emergency laryngectomy, six post bleeding (epistaxis, haemoptysis, bleed form laryngectomy site), and four post evacuation haemotoma. Three were admitted following anaphylaxis/angioedema and one after laryngospasm. Twenty-nine patients required medical management only (for example, steroids, nebulisers, and so forth), 25 were extubated post difficult intubation and six needed haemostasis control. Ten (nine surgical) tracheostomies were performed during their ICU stay. Sixteen patients died in hospital, of whom five were in the ICU at the time; 14 of these had an underlying malignancy. Twenty-three patients deteriorated during their ICU stay including HAP (n = 3), bleeding from airway (n = 3), PEA arrest (n = 1), airway swelling (n = 2), blocked laryngectomy (n = 1), and tracheostomy dislodgement (n = 1).

Conclusion Marked variation was seen in the type and aetiology of airway emergencies admitted to the ICU. A broad training programme is thus required to offer wide-ranging awareness of potential problems, communication (including an emergency airway plan), and acute management.

P206 Outcomes of medical patients requiring emergency intubation in a rural Irish hospital
A O’Connor, MP D’Alton, B Carey
Bantry General Hospital, Co. Cork, Ireland

Introduction Bantry General Hospital (BGH) is a small rural hospital serving a large, geographically isolated part of southwest Ireland. Following an influential national review of adult critical care services [1], a protocol was introduced in late 2010 mandating the immediate transfer of all medical patients intubated on an emergency basis to a large critical care centre 100 km away. Similar mandatory transfer protocols were introduced at the same time throughout the island of Ireland but few data are available regarding patient outcomes. We designed a study to look at the outcomes of all patients encompassed by the protocol at BGH.

Methods We retrospectively reviewed the charts and electronic data of medical patients requiring emergency intubation at BGH from November 2010 to December 2013. We recorded the following data: age, sex, admission diagnosis, comorbidities, time delay to transfer, in-transit mortality, length of stay, survival to discharge and 1-month and 6-month mortality.

Results Forty-five patients (31 male) were included with a mean age of 67 ± 15 years. The commonest admission diagnoses were sepsis (10), cardiogenic shock (10), primary respiratory failure (nine) and intracranial haemorrhage (eight). The median transfer delay time was 47 minutes. Only 27 (60%) patients were actually transferred and they were significantly younger than nontransferred patients (62 vs. 73 years, P = 0.02). In-transit mortality was zero. Mean length of stay in the critical care centre was 14.8 ± 16.8 days. Survival to discharge was significantly higher in transferred (14/27) compared with nontransferred (3/18) patients (52% vs. 17%, P = 0.017). Overall mortality rates were 62% and 69% at 1 and 6 months respectively and were significantly lower in the transferred group (P = 0.02).

Conclusion Overall mortality rates of medical patients intubated urgently at BGH were high. Forty per cent of intubated patients were not transferred, indicating significant modification of the protocol over time. Patients transferred to the critical care centre were younger and had significantly better outcomes than patients remaining in BGH, probably due to decisions not to transfer patients with poor prognoses. Most patients who survived to discharge were still alive 6 months later.

P207 Comparison of video laryngoscopy with direct laryngoscopy in patients with good glottic visualization: an observational study of 348 emergency intubations
Y Kato, H Okamoto, H Uchino, T Fukuoka
Kurashiki Central Hospital, Kurashiki Okayama, Japan

Introduction Video laryngoscopy (VL) is known to improve glottic visualization and the first-attempt success rate compared with direct laryngoscopy (DL) in emergency tracheal intubations (ETIs). Since VL does not align the oral, pharyngeal, and laryngeal axes of the upper airway, it sometimes leads to failed intubation despite good glottic visualization. We tested the hypothesis that VL has a lower first-attempt success rate of ETI than DL among patients with good glottic visualization.

Methods We performed a prospective observational study examining ETIs at our tertiary care institution from July 2012 to June 2014. All consecutive patients who underwent ETIs in the emergency department and ICU were included. Patients under 18 years of age, intubated with VL not using C-MAC, were excluded. After each ETI effort, the operator completed a standardized data collection form. We classified glottic visualization as good (C-L grade 1 or 2), and poor (C-L grade 3 or 4). The primary outcome was the first-attempt success rate.
The primary exposure was use of VL. Potential confounders of success rate examined were age, sex, primary indication of intubation, methods of intubation, and operator level of training and specialty. Among patients with good glottic visualization, we conducted a multivariable logistic regression adjusted for potential confounders.

**Results** A total of 348 patients were included. VL attained better glottic visualization than DL (92.3% vs. 82.6%, respectively: P < 0.001). In total, 299 patients with good glottic visualization were included in the analysis. Of these patients, 185 (61.9%) were male, median age and body mass index were 69 (interquartile range (IQR), 51 to 77) and 22 (IQR, 20 to 24) respectively. In univariate analysis, VL group had less respiratory failure (18.3% vs. 46.8%; P < 0.001) and included more trauma patients (21.1% vs. 7.9%; P < 0.001). The first-attempt success rates were similar between two groups (82.6% vs. 77.4%; P = 0.286). Multivariable logistic regression analysis adjusted for potential confounders showed that the success rate of VL was similar to that of DL (odds ratio, 1.17; 95% confidence interval, 0.57 to 2.39).

**Conclusion** Despite the possible poor alignment of airflow, the first-attempt success rate of VL is similar to that of DL among patients with good glottic visualization.

Transnasal humidified rapid insufflation ventilatory exchange for pre-oxygenation and apnoeic oxygenation during rapid sequence induction

M Maryaselvam, D Stolady, G Wijewardena, M Blunt, P Young
Queen Elizabeth Hospital, King's Lynn, UK

**Introduction** Rapid sequence induction (RSI) in the ICU, emergency department (ED) and operating room (OR) carries the risk of hypoxemia if laryngoscopy is prolonged especially in high-risk patients. Bag and mask pre-oxygenation is normally used to extend the apnoea time; however, arterial desaturation may still rapidly occur. Transnasal humidified rapid insufflation ventilatory exchange (THRIVE) is a new technique that provides modest CPAP during pre-oxygenation and crucially also continuous oxygenation of the pharyngeal space throughout the apnoea period. In elective surgery, THRIVE provides apnoea times as long as 60 minutes due to apnoeic oxygenation [1]. We report the first implementation of THRIVE with emergency patients into the ICU, ED and OR.

**Methods** Following training a THRIVE system was installed in each location either as a fixed system on the anaesthetic machine (OR) or a mobile solution on a wheeled stand (ICU, ER). This was a simplified Optiflow system (Fisher and Paykel, New Zealand) consisting of a high-flow ventilator (PVC bag and high-flow rotameter), a reusable humidifier, a reusable circuit and a disposable nasal interface. Anaesthetists of all grades were encouraged to use THRIVE (60 l/minute) prior to and during all high-risk intubations. Prospective data of pre and post intubation SpO2 and time to intubate were collected. Anaesthetists were interviewed on acceptability of the technique.

**Results** There were 62 RSI intubations using THRIVE (ICU and ED = 30; OR = 33). Difficult airway equipment used in 36 cases (videolaryngoscopy in 23). Mean apnoea time was 118 seconds (30 to 480 seconds), with a median SpO2 fall of 1% (0 to 33%). There was no correlation between arterial desaturation and apnoeic time. OR cases had a mean apnoea of 113 seconds with a median SpO2 fall of 0% (0 to 13%). ICU and ED cases had a mean apnoea time of 119 seconds and median SpO2 fall of 1% (0 to 33%). THRIVE was universally readily accepted. Reasons cited included: simplification of pre-oxygenation (hands free) and increased confidence. Six outlying arterial desaturation events suggested poor airway maintenance at induction or use in particularly high-risk patients. Many anaesthetists reintstituted THRIVE following extubation in selected patients (for example, obesity). No complications occurred during implementation.

**Conclusion** We conclude that THRIVE provides a convenient, safe and easy to implement technique for pre-oxygenation and apnoeic oxygenation during laryngoscopy.

**P209**

Airway hygiene in the ICU: can ipratropium plus salbutamol help?

N Magalhaes
Centro Hospitalar Tamega e Sousa, Penafiel, Portugal

**Introduction** β-Adrenergic agonists increase the ciliary beat frequency in experimental models, raising the possibility that they may be useful for airway hygiene [1]. Salbutamol increases large airway mucociliary clearance [2], although this may not be true for smaller airways [3]. There are no data from ICU patients, so we decided to test the effectiveness of transtracheal instillation of a mixture of ipratropium and salbutamol, assessing the reduction of the number of aspirations and hours of ventilation.

**Methods** An open randomized prospective study was held during 2014. All admitted patients were alternately selected as the study or control group and included if submitted to invasive ventilation for at least for 24 hours. Four patients who had secondary cardiac rhythm effects attributable to β-adrenergic agonists were excluded. In the study group, 3 ml of a dilution of 2.5 ml ipratropium (0.52 mg) plus salbutamol (2.5 mg) with 2.5 ml distilled water was instilled after the aspiration of secretions. During the ventilation period we noted for both groups, in addition to the demographic data, the number of aspirations and hours of ventilation.

**Results** These preliminary results included 107 patients. The only normal distribution, according to the Kolmogorov–Smirnov test and we used the Kolmogorov–Smirnov test to compare the normal distribution of the groups. There were 62 RSI intubations using THRIVE (ICU and ED = 30; OR = 33). Difficult airway equipment used in 36 cases (videolaryngoscopy in 23). Mean apnoea time was 118 seconds (30 to 480 seconds), with a median SpO2 fall of 1% (0 to 33%). There was no correlation between arterial desaturation and apnoeic time. OR cases had a mean apnoea of 113 seconds with a median SpO2 fall of 0% (0 to 13%). ICU and ED cases had a mean apnoea time of 119 seconds and median SpO2 fall of 1% (0 to 33%). THRIVE was universally readily accepted. Reasons cited included: simplification of pre-oxygenation (hands free) and increased confidence. Six outlying arterial desaturation events suggested poor airway maintenance at induction or use in particularly high-risk patients. Many anaesthetists reintstituted THRIVE following extubation in selected patients (for example, obesity). No complications occurred during implementation.

**Conclusion** We hypothesised that the simultaneous use of a heat and moisture exchanger and a heated humidifier causes critical airway occlusion in less than 24 hours

M Maryaselvam, A Doyle, G Wijewardena, N English, P Young
Queen Elizabeth Hospital, King’s Lynn, UK

**Introduction** We hypothesised that the simultaneous use of a heat and moisture exchanger (HME) and a heated humidifier (HH) would increase the incidence of airway occlusion over a 24-hour period in comparison with each device in isolation. This bench study compares the incidence of airway occlusion when using (group 1) no airway humidification, (group 2) a HME alone, (group 3) a HH alone and (group 4) both a HME and a HH in combination. Tracheal intubation requires the use of artificial humidification systems. HMEs are less efficient but convenient especially for a short period of intubation and HHs are commonly more expensive. Both devices are often used in close proximity on the ICU depending on the particular clinical scenario and/or clinical practitioner. Following a critical incident of HME obstruction due to waterlogging on our ICU we realised that HH and HME may be used together inadvertently. This airway obstruction was only resolved by the removal of the HME from the patient’s breathing circuit.

**Methods** A lung simulator underwent pressure-controlled ventilation (Pinsp = 25 cmH2O; PEEP = 5 cmH2O; VT = 500 ml) for 24 hours for seven
Endobronchial streptokinase for airway thrombus: a case series

D Lloyd, J Bornford, M Barry, W Berry, N Barrett, L Camporota, N Ioannou, B Lams, C Langrish, C Meadows, A Retter, D Wyncoll, G Glover
Gays and St Thomas’ NHS Trust, London, UK

Introduction Pulmonary haemorrhage (PH) is common in patients receiving mechanical ventilation and especially during ECMO, due to severe lung pathology and systemic anticoagulation. Whilst PH manifests as worsening ventilation and gas exchange, in ECMO patients who already have low tidal volume and who do not rely on pulmonary gas exchange, deterioration may not be evident until extensive airway thrombus (AT) has developed. Management of AT is challenging, with lavage, suctioning, mechanical disruption and extraction of limited efficacy in severe cases. Limited reports suggest that topical thrombolytics may have a role in the management of AT. We report the safety and efficacy of endobronchial streptokinase (EBSK) in patients with extensive AT.

Methods A retrospective case series in a UK ECMO centre. Patients who received EBSK between 2010 and 2014 were identified from pharmacy records.

Results Five patients were identified, 80% were male. Median age was 40 years, APACHE II score 36.5 and Murray score 3.75. Four were on ECMO with systemic heparin. All had ARDS secondary to lung infection (community-acquired pneumonia (two), lung abscess (one), TB (one) and PJP (one)). All had extensive AT, diagnosed on ECMO, on early tests for each group (n = 24). A HME (Fitla-Therm; Intersurgical, Berkshire, UK) was placed between the breathing circuit and catheter mount or the HH (MR850; Fisher & Paykel, Auckland, New Zealand) was used, or both in combination. Circuit manipulation was performed 4-hourly to simulate patient movement. Hourly Vt was recorded to determine airflow occlusion. Critical airflow occlusion (defined as a drop on the TV to <50 ml) was assessed using a Fisher’s exact test.

Results In all seven of the breathing circuits in group 4 (both a HME and a HH in combination), critical airflow occlusion occurred suddenly between 19 and 23 hours. No episodes occurred in the other three groups (P < 0.0001).

Conclusion The combination of the use of HME and HH within a single ICU risks inadvertent dual use in a single patient and if uncorrected this is likely to result in a ventilator circuit obstruction. Medical errors can be mitigated by consideration of human factors and system engineering to improve patient safety. A focus on clinical awareness and training may lead to improvements; however, the numbers, experience and turnover of critical care staffing would indicate that a systems approach is appropriate and either HME or HH should be used exclusively in an ICU.

P212

Reduction of ventilator-associated pneumonia using the AnapnoGuard system

Y Bar-Lavi1, Yaron Sasson1, Rambam Medical Center, Haifa, Israel

Introduction Ventilator-associated pneumonia (VAP) is a common complication in mechanically ventilated patients. Frequently the pathogens responsible derive from aspirated secretions of the upper respiratory tract or the stomach. In order to prevent aspiration, two missions should be attained: a good tracheal cuff seal with a well-tolerated pressure, together with continuous evacuation of secretions from the subglottic space. These two goals can be achieved using the AnapnoGuard system and its related endotracheal tube (ETT).

Methods A single-center, open-label study in a general ICU. Control group: (retrospective data) mechanically ventilated patients on standard of care regular ETT, manual suction of the trachea and oral–pharyngeal space by nursing staff. Study group: (prospective data) connected at all times to the AnapnoGuard system: an ETT with two above-the-cuff suction ports and a third port and lumen for rinsing and CO2 measurement. A triple lumen harness is connected to a control system designed to measure CO2 levels above the cuff (to identify leaks), inflate the cuff accordingly, rinse and suction secretions above the cuff. To be included in the study patients had to have no pneumonia on admission and at least 3 days of mechanical ventilation. VAP was diagnosed for a new chest X-ray infiltrate accompanied by fever, leucocytosis and positive sputum culture. The study was approved by the hospital IRB.

Results Control group: 100 patients who received standard intubation and treatment in 2009 to 2010. Of these, four dropped out due to screening failure of pneumonia on the day of enrollment. Study group: in 2011 to 2014, 192 patients were screened. Of these, 49 were found eligible and were enrolled. Of these, 14 dropped out (four screening failures with pneumonia on day of enrollment and 10 withdrawals with MV of less than 24 hours). Mean age was 51 (control) and 49 (study). Males were 75% of both groups and mean weight was 81 kg in both. VAP was diagnosed in 26 (27%) of controls and only three (8.5%) of the study group (P = 0.03). Mean time from admission to VAP diagnosis was 4.7 days in controls versus 5.12 in the study group (NS). No serious adverse events occurred.

Conclusion Patients connected to the AnapnoGuard system demonstrated a statistically significant lower VAP rate compared with the control group (8.5% vs. 27% respectively, P = 0.03). The estimated relative risk of VAP occurring in the control group was more than three times higher than the study group. Rinsing and aspiration of subglottic secretions combined with cuff pressure and seal management may be an effective method to prevent VAP.

P213

Risk factors for bleeding complications after percutaneous dilatational tracheostomy: a 10-year institutional analysis

K Pilarczyk1, G Marggraf1, M Dudasova1, E Demircioglu1, D Wendt1, B Huschens1, H Jakobi1, F Dusse1
1West German Heart Center Essen, University Hospital Essen, Germany; 2University Hospital Essen, Germany

Introduction Percutaneous dilatational tracheostomy (PDT) is the standard airway access in critically ill patients who require prolonged mechanical ventilation. Bleeding complications after PDT are infrequently observed but have a tremendous impact on further clinical course CFA risk stratification for patients scheduled for PDT.

Methods We retrospectively reviewed the records of all patients who underwent PDT (using the Ciaglia technique with bronchoscopic guidance) on our cardiothoracic ICU between 2003 and 2013. Patients were stratified into two groups: patients suffering from acute moderate, severe or major bleeding (Group A) and patients who presented none or only mild bleeding (Group B).

Results A total of 1,001 patients (46% male, mean age 68.1 years) that underwent PDT were analyzed. In the majority of patients, no or
only mild bleeding during PDT occurred (none: 425 (42.5%), mild: 488 (48.8%)). In 84 patients (8.4%), bleeding was classified as moderate. Three patients suffered from severe bleeding, only one major bleeding with need for emergency surgery was observed. Study groups showed significant differences in Simplified Acute Physiology Score (SAPS) on the day of PDT (Group A: 47.0 ± 13.1, Group B: 32.9 ± 11.2, \( P = 0.042 \)), renal replacement therapy on the day of PDT (Group A: 53 (60.2%), Group B: 439 (48.1%), \( P = 0.026 \)), presence of coagulopathy (Group A: 48 (54.5%), Group B: 393 (43.0%), \( P = 0.043 \)), platelet count (Group A: 91.6 ± 59.2, Group B: 111.5 ± 79.8 × 1,000/μl, \( P = 0.037 \)), fibrinogen levels (Group A: 373.6 ± 159.1, Group B: 450.6 ± 259.0 mg/dl, \( P = 0.012 \)), proportion of PDTs performed by residents (Group A: 72 (81.8%), Group B: 632 (69.2%), \( P = 0.034 \)) and moderately to very difficult PDT (Group A: 31 (35.2%), Group B: 141 (15.4%), \( P = 0.001 \)). Using logistic regression analyses, difficult PDT, low-experienced operator, SAPS >40 and low fibrinogen were independent predictors of relevant bleedings after PDT.

**Conclusion**

Periprocedural bleeding complications during PDT are rare. However, low fibrinogen levels as well as difficult PDT, low-experienced operator and SAPS >40 are associated with an increased risk for bleeding complications. Therefore, preprocedural risk evaluation for bleeding complications should include these factors and further studies are necessary to prove whether modification of risk factors – for example, substitution of fibrinogen prior to PDT – is able to reduce incidence of bleeding complications.

### P214

**Percutaneous dilatational tracheostomy: complications and safety without the use of bronchoscopic guidance**

R Johnsen
Sygehus Lillebaelt, Vejle, Denmark

**Introduction**

Since the introduction and development of percutaneous dilatational tracheostomy (PDT), this procedure is accepted and incorporated in ICUs worldwide. In spite of obvious benefits for the patients, who obtain more comfort and mobility and less use of sedatives, the procedure also implies the risk of several complications, some of which may be lethal. Severe complications include hemorrhage, displacement and pneumothorax. Different methods of PDT are described in the literature, each with disadvantages and benefits. The aim of this study was to analyze complications due to PDTs performed without the use of bronchoscopic assistance.

**Methods**

The study was conducted in a Danish eight-bed, non-university ICU. Since 2007, all patients admitted to the ICU have been registered on an electronic patient record system, in which daily vital values, diagnoses, procedures and healthcare providers’ notes are entered. When searching for ‘percutaneous dilatation tracheostomy’ in the electronic system, we found all patients who had undergone this specific procedure. Afterwards we analyzed each of these patients’ hospital records, looking for any periprocedure or postprocedure complications noted within 7 days. In addition we registered patients’ age, sex, BMI, SOFA score, methods used in procedures and experience of operators.

**Results** A total of 136 patients admitted to the ICU had undergone a PDT between 2007 and 2014. Of these, two were excluded due to the PDT being performed in another hospital before admission to our ICU. All 134 PDTs were performed with the Ciaglia Blue Rhino Method. No PDTs were performed with bronchoscopic guidance. In 12 cases some kind of complication due to the PDT was registered: six cases with need of surgical hemostasis, three cases of bleeding with need of transfusion of blood products, one case of PDT displacement, one case of ventilation-related problems during procedure and, finally, one case of tracheal cartilage fracture. There were no incidents of pneumothorax. No PDTs had a lethal outcome due to the procedure itself. The total complication rate was 9.0%. Of the 12 cases, four (33%) complications occurred during the procedure, the rest (66%) occurred after the procedure. The overall periprocedure complication rate was 3%. These complications were noted within 7 days of the procedure. The rest (66%) occurred after the procedure. The overall periprocedure complication rate was 3%. These complications were noted within 7 days of the procedure.

**Conclusion** In this study, PDTs without the use of bronchoscopic guidance were performed safely with a low rate of complications.
have outlined a decisional algorithm to choose the most appropriate technique in each case to reduce the incidence of complications.

Methods A retrospective review was performed using data from the last 14 years. Two hundred patients were selected. Patients were divided into two groups: one including the first 100 PDTs treated without the algorithm (nA-group) and the other including the last 100 patients treated with the algorithm (A-group). Valuation of clinical and anatomical features of the patients, neck ultrasound and fibrobronchoscopy came before the procedure [1]. The algorithm was formulated by our experience with PDT techniques, comparing the specific characteristics of each one with the physiopathological characteristics of each patient.

Results We recorded complications (bleeding, tracheoesophageal fistula, subglottic stenosis, tracheal rings’ fracture, difficulty of placement, change of procedure) related to PDTs performed with and without applying the algorithm. We considered complications that occurred in our experience and we changed our modality in technique choice (Figure 1). Compared with the complications reported in the nA-group, use of the algorithm as a guide to choose the kind of PDT technique seems to reduce the incidence of complications (37% vs. 19%; P = 0.001 chi-square test).

Conclusion In our experience, the application of the proposed algorithm in ICU patients reduce the incidence of complications related to PDT in the ICU. However, a randomized controlled multicenter study would be necessary in order to confirm the efficiency and validity of the proposed algorithm.

Impact of antibiotic therapy during a bedside percutaneous tracheotomy procedure in an ICU
E Brotsa1, A Boer1, J Kayfman1, A Frenkel1, S Grumenbaum2, A Smolikov1, A Zlotnik1, M Klein1
1Ben Gurion University of The Negev, Soroka Medical Center, Beer Sheva, Israel; 2Yale University School of Medicine, New Haven, CT, USA

Introduction Percutaneous bedside tracheotomy (PBT) is a frequently done procedure in the ICU. PBT is a clean-contaminated procedure, and the duration of the procedure is 15 to 20 minutes depending on the physician’s procedural skills. The rate of infectious complications and efficacy of perioperative therapy in reducing infections after PBT is currently unknown. Currently there have been no definitive recommendations for prophylactic antibiotic therapy before PBT in the ICU.

Methods All clinical and microbiological data were retrospectively collected and analyzed during the ICU stay before PBT performance and 72 hours after the PBT procedure from 110 patients in our ICU. Controls were defined as patients in whom the PBT procedure was performed in the ICU without antibiotics administered 72 hours prior to and during the procedure (Group 1, n = 82). Cases were defined as patients in whom the PBT procedure was performed in the ICU without antibiotics administered 72 hours prior to and during the procedure (Group 2, n = 28). Secondary bacteremia, line sepsis and VAP during the 72 hours after PBT were considered infectious complications. Two-tailed P<0.05 was considered to be significant.

Results No differences were found in age, gender, admission diagnoses, length of ICU stay and in-hospital mortality rate between the two study groups. Overall Gram-negative, Gram-positive and fungal flora were similar in both groups before and after PBT. Patients who received antibiotic therapy had a lower incidence of new ventilator-associated pneumonia (VAP) episodes (15/82 (18.2%) in Group 1 vs. 14/28 (50%) in Group 2, P <0.001 (0.23, 0.87 to 0.13)) (Table 1). There were no differences in the incidence of bacteremia or line sepsis (Table 1).

Conclusion Our findings highlight the importance of conducting a prospective randomized control trial to better understand the role of antibiotic prophylaxis in PBT.

Outcomes of patients with tracheostomy discharged from ICU to Transitional Care Unit and general wards
J Rubio1, JA Rubio2, E Palma1, R Sierra1, F Carmona1, F Fuentes2
1Hospital Universitario Puerta del Mar, Cadiz, Spain; 2Hospital Infantia Cristina, Badajoz, Spain

Introduction Patients with a tracheostomy (TQ) tube in place discharged from the ICU to a general ward (GW) are a fragile group and the TQ may be a risk factor for morbidity and mortality [1,2]. For this reason they need closer monitoring and more airway care. The Transitional Care Unit (TCU) assists patients with serious medical conditions and bridges the gap between the ICU and home or long-term care facilities providing the necessary medical, nursing, psychological and rehabilitative care. The purpose of this study was to evaluate the impact of the TCU on outcomes of tracheostomized patients discharged from the ICU.

Methods We retrospectively reviewed medical records of ICU adults patients who had TQ when discharged to a new TCU and to a GW. The study was carried out in two tertiary care university hospitals from January 2007 to November 2014. Study variables were age, sex, APACHE II score, principal diagnosis, associated major procedures, length of stay in ICU and out in hospital, TCU and GW, Sabadell score, in-hospital mortality, types of tracheostomy procedure, decision to decannulate and discharge to home or long-care facilities.

Results In total 12,839 records of patients discharged from the ICU were analyzed. Tracheostomy was present in 133 patients. Two groups were defined: (1) TCU (n = 56) and (2) GW (n = 77). Patients of the TCU group were older (60.1 ± 13.1 vs. 54.9 ± 15.8 years; P < 0.05) with higher APACHE II score (23 (CI: 21.5 to 25.8) vs. 18.5 (CI: 17.1 to 19.9); P < 0.001), and had longer stay in the ICU (45.8 (CI: 38.2 to 53.3) vs. 28.4 (CI: 24.2 to 32.6) days; P < 0.001) and on the ward (71.1 (CI: 57.4 to 84.8) vs. 46.1 (CI: 33.7 to 58.2) days; P < 0.001) than those of the GW group. The GW group had category 1 of Sabadell score more frequently than the TCU group (25.9% vs. 8.9%; P = 0.019). Rates of nosocomial infections were similar in both groups. No significant differences on vasoactive use (50.9% vs. 40.2%), renal failure (23.2% vs. 20.7%), blood transfusions (25% vs. 22.4%), parentral nutrition (10.7% vs. 12.9%), in-hospital deaths (14.3% vs. 24.6%), decannulation (55% vs. 50%), or discharge to home (53.6% vs. 37.7%) were found between groups 1 and 2, respectively.

Conclusion In our setting the TCU helps to care more safely for severe tracheostomized patients after ICU discharge, and furthermore facilitates discharge home.

Rapid amelioration of respiratory parameters in severely obese patients after percutaneous dilatational tracheotomy
S Kaese, M Zander, J Waltenberger, P Lebiedz
University Hospital of Muenster, Münster, Germany

Introduction Incidence of obesity in developed countries is rising. Currently, Europe has a prevalence of 9 to 30% with significant impact on public health systems. Obese patients in the ICU require special management and treatment. Altered anatomy in obese patients complicates procedures such as mechanical ventilation. Obesity affects cardiopulmonary physiology and requires elevated ventilation pressures. In our retrospective study, we determined the effect of early
percutaneous dilatational tracheotomy (PDT) and cessation of sedation on respiratory parameters in severely obese patients.

**Methods** From June 2010 to July 2014, we included all patients with a body weight of >130 kg, respiratory failure and PDT who were admitted to the ICU of the University Hospital of Muenster. We compared respiratory parameters and blood gas analysis before and after PDT. Parameters were recorded on days –1, 0, 1, 3, 5, and 10, with day 0 describing the day of PDT.

**Results** Twenty-one patients were included in the study. Mean age was 56 ± 10.3 years and 14 (66.7%) of the patients were male. Body weight was 164.5 ± 39.4 kg, body height accounted for 176.8 ± 8.7 cm (n = 20) and body mass index was 49.7 ± 16.9 kg/m². Patients stayed in the ICU for 18.4 ± 13.8 days. Mean time of mechanical ventilation by endotracheal tube was 2.4 ± 1.5 days (n = 20) and via tracheostomy 9.8 ± 7.0 days. After PDT, peak inspiratory pressure (P < 0.0001), positive end-expiratory pressure (P < 0.0001) and insufflated oxygen concentration (P < 0.0001) could significantly and rapidly be reduced. Respiratory minute volume increased significantly (P = 0.004). PDT was not associated with relevant complications.

**Conclusion** Early PDT rapidly improves respiratory distress in severely obese patients due enabling of spontaneous breathing and reduction of dead space ventilation.

**P219**

**Early postoperative use of CPAP reduces need for unplanned IPPV in elective vascular patients**

**H Kennedy, J Navein, J Seidel**

Doncaster Royal Infirmary, Sheffield, UK

**Introduction** Respiratory failure is a well-known complication of aortic aneurysm surgery. We describe the impact of a protocol, using CPAP after elective surgery to reduce the need for unplanned invasive ventilation.

**Methods** In 2012 we introduced a CPAP protocol for patients undergoing elective aortic aneurysm surgery, either open (AAA) or as an endovascular repair (EVAR). According to pre-existing risk factors (see Table 1) and arterial blood gas analysis in the anaesthetic room, they were assigned to two alternative options on the ITU: prophylactic CPAP for 9 hours in each of the first two postoperative nights or oxygen via face mask. CPAP was applied at any time in the patients stay, if their P/F ratio dropped below 40. Criteria to stop CPAP were also predefined. Previously, CPAP was initiated at the discretion of nursing staff. P/F ratios were not utilised.

**Results** We compare patient cohorts in the years 2010 and 2011 (pre protocol) with 2013 and 2014 (post protocol). Results are reported as the split between open surgery and endovascular repair. Table 2 presents requirements for invasive ventilation (IPPV) and length of stay (LOS) for both patient groups.

**Conclusion** There is a clear reduction in the need for unplanned IPPV in both patient groups. An audit in 2013 showed incomplete protocol adherence in the ITU, therefore benefits may be underestimated.

**P220**

**Is the gastric tube a burden for noninvasive ventilation?**

**I Minev, C Stefanov**

University Hospital St. George, Plovdiv, Bulgaria

**Introduction** The application of noninvasive ventilation (NIV) in ICUs has spread widely during the years. It is used in the treatment of different forms of acute respiratory failure and COPD exacerbations. Although NIV is thought to be more comfortable for patients than invasive mechanical ventilation, its failure rates in the ICUs range between 10 and 40%. Except for the interface-related problems, there are some specific considerations for the patient–ventilator interaction and the applied mechanical forces. During NIV there is a predisposition for the stomach to be inflated with gas, which could cause severe respiratory complications, especially in COPD patients, and thus prolong the mechanical ventilation and the weaning process. This remains one of the major causes for NIV failure. Although a lot of face masks with different interfaces are available on the market, just a few have additional ports for a NGT. They are characterized by higher price and a complex setup. In order to perform NIV in patients, requiring NGT placement, without additional air leaks and to be able to ensure their enteral nutrition and/or stomach drainage, we installed a port for a NGT on a standard face mask.

**Methods** In this study, six of the COPD patients admitted to our ICU, who required NGT placement, were ventilated with the Draeger Evita 2 dura through a modified reusable silicone face mask [UMDNS code: 12-453 with 22 mm ID connection; sizes 4 and 5] with silicone headgear and a hook ring. All of them had a NGT during their stay in the ICU. We evaluated the efficacy of our modification comparing the achieved Vt with modified and unmodified face mask, during two periods of 10 minutes. The mode and parameters of ventilation were not changed. We assessed patient comfort with a visual analogue scale.

**Results** The average duration of NIV was 3.5 days (SD = 1.6). We examined two sets of 10 consequent breathing cycles for every patient. The mean Vt was 472 ml (SD = 76 ml) with standard face mask and 460 ml (SD = 86 ml) with the modified one. There was statistically significant correlation between the two datasets (P < 0.05). No additional leaks were detected. According to the VAS evaluation, five of the patients (83%) had comfort improvement with the modified mask.

**Conclusion** With this modification of the face mask we achieved adequate drainage of the stomach and/or enteral nutrition of the patients and improvement in their comfort during NIV, compared with the ventilation with a standard mask, without additional air leaks and at a low cost.

**Lung ultrasonography as a marker of pulmonary edema in cardiac surgery patients: visual versus quantitative evaluation**

**F Corradi, C Brusasco, T Manca, F Nicolini, F Nicosia, T Gherli, V Brusasco, A Vezzani**

1Ente Ospedaliero Ospedali Galliera Genova, Italy; 2Università degli Studi di Genova, Italy; 3Azienda Ospedaliero-Universitaria di Parma, Italy

**Introduction** Lung ultrasonography (LUS) has been used for non-invasive detection of pulmonary edema. LUS visual scores (V-LUS) based on B-lines are poorly correlated with either pulmonary capillary wedge pressure (PCWP) or extravascular lung water (EVLW). A new quantitative LUS analysis (Q-LUS) has been recently proposed [1,2]. The aim of the study was to investigate whether Q-LUS is better correlated with PCWP and EVLW than V-LUS, and to what extent positive end-expiratory pressure (PEEP) affects the assessment of pulmonary edema by Q-LUS and V-LUS.

**Table 1 (abstract P219). Criteria for the use of prophylactic CPAP**

| Current smoker |
| Poor exercise tolerance (<100 yards) due to chest problems |
| SpO₂ <92% on air |
| SpO₂ <92% on FiO₂ >0.4 in theatre |

**Results** We compare patient cohorts in the years 2010 and 2011 (pre protocol) with 2013 and 2014 (post protocol). Results are reported as the split between open surgery and endovascular repair. Table 2 presents requirements for invasive ventilation (IPPV) and length of stay (LOS) for both patient groups.

Methods Thirty-nine patients mechanically ventilated with PEEP of 5 cmH₂O \((n = 47)\) or 10 cmH₂O \((n = 30)\) and PCWP \((n = 77)\) or EVLW \((n = 30)\) monitored were studied.

Results PCWP was significantly and strongly correlated with Q-LUS Grey Unit value \((r^2 = 0.64)\) but weakly with V-LUS B-line score \((r^2 = 0.19)\). EVLW was significantly and strongly correlated with QLUS Grey Unit mean value \((r^2 = 0.65)\) more than with V-LUS B-line score \((r^2 = 0.42)\). Q-LUS showed a better diagnostic accuracy than V-LUS for the detection of PCWP \(>15\) mmHg or EVLW \(>10\) ml/kg. With a PEEP of 5 cmH₂O, the correlations with PCWP or EVLW were stronger with Q-LUS than V-LUS. With a PEEP of 10 cmH₂O, the correlations with PCWP or EVLW were still significant for Q-LUS but insignificant for V-LUS. Intraobserver repeatability and interobserver reproducibility were much better for Q-LUS than V-LUS.

Conclusion Both V-LUS and Q-LUS are acceptable indicators of pulmonary edema in patients mechanically ventilated with low PEEP but at high PEEP only Q-LUS provides data that are significantly correlated. Computer-aided Q-LUS has the advantages of being not only independent of operator perception but also of PEEP.

P222 Lung ultrasound aeration assessment: comparison of two techniques

S Mongodi, F Mojoli, A Stella, I Godi, G Via, G Tavazzi, A Orlando, B Bouhemad,1
1Fondazione IRCCS Policlinico S. Matteo Hospital – University of Pavia, Italy;
2Centre Hospitalier Universitaire Dijon, France

Introduction Lung ultrasound (LUS) allows semiquantification of lung aeration in PEEP trials [1], pneumonia [2] and weaning [3]. LUS score is based on number/coallescence of vertical artifacts (B-lines) in longitudinal scan (LONG) [4]: the pleura is identified between two ribs and its visualization limited by intercostal bone CT width. We hypothesized that a transversal scan (TRANSV) aligned with ICS would visualize longer pleura and a higher number of artifacts, with better assessment of loss of aeration (LoA).

Methods LONG and TRANSV were performed in six areas per lung (anterior, lateral and posterior, each divided into superior and inferior). Once LONG was performed, TRANSV was obtained by a probe rotation until the ribs disappeared. We considered pleural length, B-line number/coallescence, and subpleural/sublobar consolidations. LUS score was assigned: 0 normal lung, 1 moderate LoA (3 well-spaced B-lines), 2 severe LoA (coallescent B-lines), 3 complete LoA (tissue-like pattern).

Results We enrolled 38 patients (21 males, age 60 ± 16 years, BMI 24.7 ± 4.7 kg/m²) corresponding to 456 ICs. In 63 ICs, a tissue-like pattern was visualized in both techniques. In the other 393, LONG versus TRANSV pleural length was 2.0 ± 0.6 cm (range 0.8 to 3.8; variance 0.31) versus 3.9 ± 0.1 cm (range 3.0 to 4.3; variance 0.1) \((P < 0.0001)\). B-lines per scan were 1.1 ± 1.6 versus 1.8 ± 2.5 \((P < 0.0001)\), coallescent B-lines were detected in 24 versus 30% \((P < 0.05)\) and subpleural consolidations in 12 versus 22% \((P < 0.05)\), respectively. LUS scores’ prevalence significantly differed in LONG versus TRANSV (Figure 1).

Conclusion TRANSV visualizes significantly longer pleura and greater number of artifacts useful for lung disease assessment.

P223 Ultrasound assessment for extravascular lung water in patients with septic shock

P Piromponrach1, A Wattanatham2
1Thammasat University, Pathumthani, Thailand; 2Phramongkutklao Hospital, Bangkok, Thailand

Introduction Extravascular lung water (EVLW) refers to fluid within the lung but outside the vascular compartment. Increment of EVLW was associated with mortality in critically ill patients. Extravascular lung water index (EVLW) > 10 ml/kg was found in patients with cardiogenic pulmonary edema and correlated with pulmonary capillary wedge pressure > 20 mmHg. Measurement of EVLW needs sophisticated tools and an invasive method by transpulmonary thermodilution (TPTD) technique. In contrast, multiple B-lines by lung ultrasound (LUS) have been recently proposed to correlate with increased EVLW in patients with pulmonary edema. This study aims to compare three methods of LUS and EVLWI measured by TPTD to assess pulmonary edema in patients with septic shock.

Methods The authors prospectively enrolled 17 patients with septic shock who were admitted to the medical ICU, Phramongkutklao Hospital between September 2013 and June 2014. EVLWI was measured by TPTD (VolumeView Set, EV1000; Edwards Lifesciences) method. According to international evidence-based recommendations for point-of-care lung ultrasound 2012, three methods of LUS (LOGIQ e ultrasound; GE Healthcare) were compared to assess EVLW daily in each patient until no indication for invasive blood pressure monitoring [1]. Firstly, B-lines were measured in 28 lung zones. The total numbers of B-lines seen in each patient were counted as total B-line scores (TBS). Secondly, upper and lower BLUE points were anterior two-region scans each side marked by physician hands. Pulmonary edema was diagnosed if three or more B-lines were presented in all regions. Lastly, scanning eight regions, two anterior and two laterals per side, was considered abnormal if more than one scan per side had three or more B-lines.

Results A total of 40 comparisons were obtained. Significant positive linear correlations were found between TBS and EVLWI determined by TPTD \((r = 0.637, P < 0.001)\). The TBS ≥ 39 has sensitivity of 91.7% and specificity of 75.0% to define EVLWI > 10 ml/kg. There was low sensitivity (33.3% and 50.0% respectively) but high specificity (100% and 96.0% respectively) of the positive BLUE points and eight regions to define EVLWI > 10 ml/kg.

Conclusion TBS is the best method for assessing EVLWI compared with BLUE points and eight regions. These data support the benefit of LUS with summation of B-line scores of 28 rib interspaces for assessment of the increment of EVLWI in septic shock patients.

P224 Atrophy of diaphragm muscle visualized with ultrasound in mechanically ventilated patients

T Schepens, M Mergay, W Verbrugghe, P Parizel, M Vercauteren, PG Jorens
Antwerp University Hospital, Edegem, Belgium

Introduction Mechanical ventilation (MV) induces diaphragmatic muscle atrophy and contractile fibre dysfunction, the so-called ventilator-induced diaphragm dysfunction (VIDD). Although
diaphragmatic atrophy can be assessed using ultrasound, the biggest trial in humans published so far included seven patients and only measuring the thickness at two moments during the disease process [1]. We aimed to assess the time course of diaphragm atrophy in a larger cohort of MV patients using ultrasound.

**Methods** A total of 54 patients from an adult ICU were included in this prospective single-centre cohort trial. Patients who needed <72 hours of MV or had been recently admitted to an ICU were excluded. Patients were ventilated in a controlled, assisted, and/or hybrid ventilation mode. The thickness of the diaphragm was assessed daily; the first recording was within 24 hours after the start of mechanical ventilation and we continued the measurements until the patients were extubated or tracheotomised. We measured the diaphragm at the zone of apposition, as described by McCool and colleagues [2] using a linear 13 MHz ultrasound probe. Figure 1 shows a sample measurement.

**Results** We were successfully able to record the diaphragm thickness in all included patients. Median time on the ventilator was 9 days (IQR 4 to 15 days). Mean baseline thickness was 1.9 mm (SD ±0.4 mm), and mean nadir was 1.3 mm (SD ±0.4 mm), corresponding with a mean change in thickness of 32% (SD ±18%). As early as after only 72 hours of MV, we already noted an average drop of diaphragm thickness of 20%, illustrating the rapid progression of the atrophy in VIDD.

**Conclusion** On average, diaphragm thickness decreased 32% in our cohort. The decrease occurred rapidly, with two-thirds of the maximal thinning already present after 72 hours of MV.

Quantitative ultrasonography for pneumonia
F Corradi1, C Brusasco2, T Manca1, F Nicosa1, A Vezzani1, V Brusasco2
1Ente Ospedaliero Ospedali Galliera Genova, Italy; 2Università degli Studi di Genova, Italy; 3Azienda Ospedaliero-Universitaria, Parma, Italy

**Introduction** Chest X-ray is recommended for routine use in patients with suspected pneumonia, but its use in emergency settings is limited. In this study, the diagnostic performance of a new method for quantitative analysis of lung ultrasonography was compared with chest X-ray and quantitative or visual ultrasonography.

**Results** Quantitative ultrasonography showed higher sensitivity (93%), specificity (95%), and diagnostic accuracy (94%) than chest X-ray (64%, 80%, and 69%, respectively), or visual ultrasonography (68%, 95%, and 77%, respectively), or their combination (77%, 75%, and 77%, respectively).

**Conclusion** Quantitative lung ultrasonography was considerably more accurate than either chest X-ray or visual ultrasonography in the diagnosis of community-acquired pneumonia and it may represent a useful first-line approach for confirmation of clinical diagnosis in emergency settings.

**References**
traditional parametric sample size estimations depend upon restrictive assumptions that often do not hold in real data. This study estimates \( N \) to detect changes in length of mechanical ventilation (LoMV) using Monte Carlo simulation (MCS) and mechanical ventilation (MV) data to better simulate the cohort.

**Methods** Data from 2,534 MV patients admitted to Christchurch Hospital ICU from 2011 to 2013 were used. \( N \) was estimated using MCS to determine a sample size with power of 80%, and compared with the Altman’s nomogram for two patient groups, (1) all patients and (2) targeted patients with 1 < LoMV ≤ 15 days. MCS allows any range of intervention effect to be simulated, where this study tested a 10 and 25% difference in LoMV (0.5 to 1.25 days for mean LoMV of 5 days). The simulated LoMV for the intervention group is compared with the LoMV in a control group using the one-sided Wilcoxon rank-sum test, Student’s t test, and Kolmogorov–Smirnov test to assess central tendency and variation.

**Results** The distribution of LoMV is heavily skewed. Altman’s nomogram assumes a normal distribution and found \( N \) > 1,000 to detect a 25% LoMV change. Figure 1 panels (1) and (2) show \( N \) for 80% power if all patients were included, and panels (3) and (4) for the targeted patient group. Panels (1) and (3) show that it is impossible to achieve 80% power for a 10% intervention effect. For 25% effect, MSC found \( N \) = 400/arm (all patients) and \( N \) = 150/arm (targeted cohort).

**Conclusion** Traditional parametric sample size estimation may overestimate the required patients. MCS can estimate effective \( N/\text{arm} \) and evaluate specific patient groups objectively, capturing local clinical practice and its impact on LoMV. It is important to consider targeting specific patient groups by applying patient selection criteria that can be easily translated into trial design.

**Non-invasive respiratory volume monitoring for quantification of respiratory depression after benzodiazepine administration**

G Mullen1, D Lad1

1Vidant Medical Center, Greenville, NC, USA; 2Respiratory Motion, Inc., Waltham, MA, USA

**Introduction** Benzodiazepines are used in many of settings to induce sedation, but can cause a reduction in respiratory drive. Objective monitoring of the effect of benzodiazepines on respiratory status in non-intubated patients has been difficult, putting patient safety at risk. A non-invasive respiratory volume monitor (RVM) that provides continuous measurement of minute ventilation (MV), tidal volume (TV) and respiratory rate (RR) was used to quantify the effects of midazolam on respiratory status in spontaneously breathing patients.

**Methods** An impedance-based RVM (ExSpiron; Respiratory Motion Inc., Waltham, MA, USA) was used in 30 patients who received 2 mg midazolam prior to induction of anesthesia and were sedated but spontaneously breathing. Eleven of these patients (58 ± 19 years, average BMI 27.7) received midazolam at least 20 minutes prior to induction. Digital RVM data were collected and MV, TV and RR calculated and evaluated from 30-second segments 10 minutes before and after the first dose of midazolam. Ten patients were analyzed as a group and one patient was analyzed separately (due to idiosyncratic reaction).

**Results** Following administration of midazolam, the group MV and TV decreased an average of 19 ± 7% and 16 ± 5%, respectively (mean ± SEM, \( P < 0.01 \)) while RR remained essentially unchanged (decrease of 3 ± 8%, \( P > 0.3 \)). In the younger half of the cohort (45 ± 16 years), the decreases in MV and TV were not significant, only 6 ± 3% and 8 ± 5%, respectively. The older half of the cohort (72 ± 8 years) displayed fourfold greater MV and TV decreases (32 ± 11%, \( P < 0.05 \) and 25 ± 6%, \( P < 0.05 \)), when compared with the younger cohort, \( P < 0.01 \), Figure 1).

**Conclusion** Continuous monitoring with RVM provides a valuable depiction of hypoventilation from benzodiazepines, not demonstrated by other methodologies such as pulse oximetry and RR alone. RVM monitoring can help uncover potentially life-threatening hypoventilation in older patients. Further studies are ongoing to quantify hypoventilation after administration of other anesthetic medications.

P229

**Nebulized heparin for patients under mechanical ventilation: a conventional data meta-analysis**

GJ Glas1, A Serpa Neto2, J Horn1, MJ Schultz1

1Academic Medical Center, Amsterdam, the Netherlands; 2Hospital Israelita Albert Einstein, São Paulo, Brazil

**Introduction** Mechanical ventilation has the potential to induce pulmonary coagulopathy. Local treatment by nebulization of heparin could be beneficial in ventilated patients. The aim of this data meta-analysis is to determine the association between nebulization of heparin and outcome of mechanically ventilated critically ill patients.

**Methods** PubMed, Scopus, EMBASE, and Web of Science were searched for relevant articles. Articles were selected if they compared...
nebulization of heparin with standard care. The primary endpoint was overall mortality. Secondary endpoints included occurrence of pneumonia and number of ventilator-free days and alive at day 28.

**Results**

Six articles were found: five retrospective cohorts with historical controls, one randomized controlled trial, covering 423 patients. Dosages of nebulized heparin varied from 30,000 to 150,000 IU/day. Fifty out of 222 patients (22.5%) receiving nebulized heparin and 48 out of 201 patients (23.9%) receiving standard care died (risk ratio (RR) 0.79 (95% CI 0.47 to 1.35)) (see Figure 1). Occurrence of pneumonia (RR 1.36 (95% CI 0.54 to 3.45); I² = 31%), and number of ventilator-free days and alive at day 28 (standardized mean difference 0.11 (95% CI –0.14 to 35); I² = 0%), were not different between the two groups.

**Conclusion**

Nebulization of heparin is not associated with improved outcome in mechanically ventilated critically ill patients. This meta-analysis is limited by methodological problems in most included studies. Only one randomized controlled trial could be included. Also, most patients in the meta-analyzed studies suffered from inhalation trauma, and heparin dosages differed widely.

**Diagnosis of obstructive sleep apnea with respiratory polygraph in hypercapnic ICU patients**

G Gursel, A Zerman, M Aydoglu, B Basarik Aydogan, K Gonderen, S Memmedova, N Sevimli, I Koroglu, Z Isikdogan, M Badoglu, O Ozdedeoglu

Gazi University-Medical Faculty, Ankara, Turkey

**Introduction**

The most frequent reasons for hypercapnic respiratory failure (HRF) in ICUs are COPD and in recent years obesity hypoventilation syndrome (OHS) and obstructive sleep apnea (OSA). Even 15 to 30% of COPD patients also have accompanying OSA. Due to increased upper airway resistance, those patients require higher expiratory pressures (EPAP) during noninvasive ventilation (NIV). In order to prescribe optimal mode and pressures during the ICU stay and at discharge, the intensivist should diagnose the underlying OSA. Portable recording devices have been developed and they were approved at least for the diagnosis in high pretest probability patients with results equal to in-laboratory polysomnography. The aim of this study is to assess whether respiratory polygraphy (RPLG) can be used for obtaining diagnostic information of OSA in hypercapnic ICU patients.

**Methods**

Patients, with HRF requiring NIV, were included in the study. RPLG studies were conducted under nasal oxygen before NIV, using the Philips Respironics Alice PDx® device, which provides the records of pulse oximetry with derived heart rate; snoring and nasal airflow with nasal pressure transducer and nasal thermistor; rib cage, abdominal motion and body position with abdominal and thoracic belts. American Academy of Sleep Medicine 2014 recommendations were used for the diagnosis of OSA and OHS. Because of the diagnostic difficulties of hypopnea in hypoxemic patients, we evaluated only the obstructive apnea index (OAI) instead of the apnea hypopnea index (AHI). All patients, and EPAP levels were increased. Laboratory sleep study was recommended to 19% of the patients. At the end of the study 56% of the COPD and 72% of the OHS patients were identified to have OSA.

**Conclusion**

Although it underestimates AHI, RPLG is important and technically feasible in ICU patients in suggesting the presence of OSA and in providing information for appropriate NIV management.
A variety of IMT techniques were employed including inspiratory threshold loading (eight studies), biofeedback to increase inspiratory effort (one study), chair-sitting (one study) and diaphragmatic breathing pattern training (one study). Threshold loading was achieved by application of an external device (six studies) or increases in the inspiratory pressure trigger setting (two studies). Most studies implemented IMT in the weaning phase (n = 5) or after difficult weaning (n = 5); one study implemented IMT within 24 hours of intubation. IMT was associated with greater increases in maximal inspiratory pressure compared with control (six studies, mean difference 7.6 cmH2O, 95% CI 5.8, 9.3), P = 0.01. There were no significant differences in the duration of MV (six studies, mean difference –1.1 days (95% CI –2.5, 0.3), P = 0.71) or the rate of successful weaning (Figure 1; five studies, risk ratio 1.13 (95% CI 0.92, 1.40), P = 0.58). The GRADE quality of evidence was low for all these outcomes; risk of bias was high for most studies and summary effects were imprecise and inconsistent. No serious adverse events related to IMT were reported.

Conclusion IMT in mechanically ventilated patients appears safe and well tolerated and improves respiratory muscle function. IMT was not associated with accelerated liberation from mechanical ventilation. However, because the included studies had important methodological limitations and employed varying methods of IMT, we cannot draw firm conclusions about the effect of IMT on clinical outcomes.

Prospective assessment of the ability of rapid shallow breathing index computed during a pressure support spontaneous breathing trial to predict extubation failure in ICU

G Beschin1, J Revelly1, P Jolliet1, L Piquilloud-Imboden1,2
CHRU Besançon, France; CHRU, Lausanne, Switzerland

Introduction As the objective clinical criteria [1] are imperfect to assess patients before extubation, simple physiological parameters are used to try to improve extubation failure (EF) prediction. The rapid shallow breathing index (RSBI) (respiratory rate (RR) over tidal volume (VT) ratio) recorded during a T-piece spontaneous breathing trial (SBT) is known as the most reliable physiologic predictor. However, RSBI is nowadays usually computed during a pressure support (PS) SBT using the values displayed on the ventilator screen and not based on spirometry measurements without any assist as initially published. The aim of the present study was to prospectively assess the ability of currently measured RSBI to predict EF.

Methods Retrospective analysis of prospectively collected data from patients intubated for more than 48 hours admitted in the medicosurgical ICU of Lausanne, Switzerland, from January 2007 to December 2008. EF was defined as the need for reintubation within 48 hours after extubation. Reintubations for a procedure requiring general anesthesia were not considered as EFS. RR and VT during the PS SBT were recorded from the ventilator and RSBI was computed accordingly. Baseline characteristics and currently measured RSBI were compared between patients who experienced EF versus success (t test or chi-square test as appropriate). The ability of currently measured RSBI to predict EF was assessed using ROC curve analysis.

Results A total of 478 extubated patients were included, 25 of whom (5.2%) were reintubated. ICU mortality (ICU-m) and in-hospital mortality (H-m) were higher in reintubated patients: ICU-m = 6 (24) versus 22 (5), P = 0.002 and H-m = 9 (36) versus 63 (15), P = 0.009. The reasons for EF were: acute lung failure (n = 15), congestive heart failure (n = 4) and aspiration/bronchial congestion (n = 6). Demographic data were similar between patients successfully and nonsuccessfully extubated: age: 58 ± 17 versus 58 ± 19 years, P = 0.85; male gender: 15 (60) versus 263 (61), P = 0.99. SAPS II score was higher in the EF group: 30 ± 22 versus 42 ± 27, P = 0.04. RSBI were significantly higher in patients who experienced EF: RSBI=59 ± 44 versus 43 ± 26, P = 0.04. The area under the ROC curve of currently measured RSBI was: 0.617 (95% CI = 0.571 to 0.662), P = 0.035.

Conclusion In a cohort of 458 medicosurgical ICU patients, RSBI measured during a pressure support SBT was higher in patients experiencing EF but very imperfect to predict EF.

Presence of neutrophil extracellular traps in bronchial aspirate of patients diagnosed with acute respiratory distress syndrome or acute exacerbation of idiopathic pulmonary fibrosis

M Ojima1, N Yamamoto2, T Hirose3, S Hamaguchi4, N Matsumoto5, R Takegawa6, M Seki6, O Tasaki7, K Tomono7, T Shimazu1
1Osaka University Graduate School of Medicine, Suita, Japan; 2Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Introduction Neutrophil extracellular traps (NETs) are fibrous structures that are produced extracellularly from activated neutrophil. They can trap and kill various pathogens, and their release is one of the first lines of immune system. Meanwhile, recently it was reported that NETs also exert adverse effects in inflammatory diseases. Acute respiratory distress syndrome (ARDS) and acute exacerbation of idiopathic pulmonary fibrosis is acute-onset respiratory failure. It is characterized by excessive neutrophil infiltration into the alveolus, and great amounts of neutrophil elastase are released. The purpose of this study is to evaluate whether NETs are produced in bronchial aspirate of patients with ARDS or acute exacerbation of idiopathic pulmonary fibrosis, and to identify correlations with the respiratory function.

Methods This was a prospective observational study of seven patients admitted to the ICU of a large urban tertiary referral hospital. All patients were mechanically ventilated at the time of admission. The bronchial aspirates were collected serially from the patients by suction through a tracheal tube. To identify NETs, extracellular components including DNA, histone H3, and citrullinated histone H3 were simultaneously detected using immunohistochemistry. The respiratory function was evaluated by PaO2/FiO2, ratio (P/F ratio).

Results The study group was comprised of four men and three women. Median age was 69 (IQR: 61.0 to 72.5) years old. The reason for admission was ARDS (n = 5) and acute exacerbation of idiopathic pulmonary fibrosis (n = 2). The reasons for ARDS are bacterial pneumonia (n = 3), necrotizing fasciitis (n = 1) and extensive burn (n = 1). We identified NETs in the bronchial aspirates of all the patients. NET formation had persisted in four cases during the study period, their P/F ratio did not improve and all patients were dead due to respiratory failure. On the other hand, NETs decreased and vanished in three cases, their P/F ratio improved and all patients recovered from ARDS.

Conclusion NET formation was observed in bronchial aspirates of all the patients diagnosed with ARDS or acute exacerbation of idiopathic pulmonary fibrosis. It may be one of the prognostic factors of ARDS or acute exacerbation of idiopathic pulmonary fibrosis.

P234
New molecules controlling endothelial barrier

S Jalkanen
University of Turku, Finland

Introduction Acute lung injury (ALI) and its hypoxemic form, acute respiratory distress syndrome (ARDS), has no approved pharmacological treatment and is a condition with high mortality. Vascular leakage is one of the early events of ALI/ARDS. CD73 activity (ecto-5’-nucleotidase) maintains the endothelial barrier function of lung capillaries via its enzymatic endproduct adenosine. Interferon-beta (IFNβ) increases synthesis of CD73 and has been effective in a mouse model of ALI.[1]

Methods Therefore we conducted a phase I/I trial [2], in which intravenously administered human recombinant IFNβ1a (FP-1201) was used in the study, which consisted of dose escalation (phase I) and expansion (phase II) parts to test the FP-1201 safety, tolerability and efficacy in ALI/ARDS patients. CD73, MxA (a marker for IFN β response) and other biomarkers were measured to follow pharmacokinetics/dynamics of the intravenously administered FP-1201 and therapeutic efficacy.

Results The optimal tolerated dose of FP-1201 (10 μg/day for 6 days) resulted in maximal MxA stimulation. Also soluble CD73 values increased, while IL-6 decreased in sera of the FP-1201-treated ALI/ARDS patients. The overall mortality of the 37 patients treated with FP-1201
was only 8.1%, fourfold to fivefold less than the expected rate based on APACHE II score values of 21.9. The control group (n=59), which was eligible for the trial but not possible to recruit, had mortality of 32.2% (P < 0.01) and APACHE II score 23.0.

**Conclusion** Restriction of vascular leakage with FP-1201 seems to significantly benefit ALI/ARDS patients. Our results suggest that FP-1201 could be the first effective, mechanistically targeted, disease-specific pharmacotherapy for patients with ARDS. However, these findings warrant conduction of a large multicenter study to establish specific pharmacotherapy for patients with ARDS.

**Endocan can be a predictive marker of severity of sepsis but cannot be a marker of acute respiratory distress syndrome in ICU patients**

M Mizunuma, H Ishikura, Y Nakamura, K Muranishi, S Morimoto, H Kaneyama, Y Izutani, T Nishida, A Murai

Fukuoka University Hospital, Fukuoka, Japan

**Introduction** Endocan (endothelial cell specific molecule-1), a 50 kDa dermatan sulfate proteoglycan, is expressed by endothelial cells in the lung and kidney. It was reported that the serum Endocan level is related to the severity of sepsis and positive correlation with the mortality rate. On the other hand, it was also reported that lower levels of serum Endocan are associated with subsequent development of chronic kidney disease, and chronic liver disease acute lung injury (ALI) in trauma patients. The aim of this study is confirmation of the relationship between serum Endocan level and the severity of sepsis, and also the severity of acute respiratory distress syndrome (ARDS) in septic patients.

**Methods** This study was conducted as a single-center, retrospective, observational study in the emergency department of Fukuoka University Hospital from April 2010 to August 2013. Blood samples were collected from patients who were diagnosed with ARDS. In this study, we used the Berlin definition as the categorized of ARDS severity. Furthermore, we evaluated the extravascular lung water index (EVLWI) and pulmonary vascular permeability index (PVPI) as a condition of ARDS using the transpulmonary thermodilution method. Additionally, 10 healthy donors were entered as a control. The patients were divided into nonsepsis, severe sepsis and septic shock groups using the ACCP/SCCM guidelines.

**Results** We enrolled 70 ARDS patients during the investigation periods. We met six patients with nonsepsis, 27 with severe sepsis and 37 with septic shock. The serum Endocan levels were significantly higher in patients with septic shock (3.2 to 3.9 ng/ml) than in patients with severe sepsis (1.7 to 2.3 ng/ml, P < 0.05), nonsepsis (0.6 to 0.3 ng/ml, P < 0.05) and healthy donors (0.4 to 0.1 ng/ml, P < 0.05). However, there was no significant correlation between the Endocan level and the severity of ARDS. In addition, significant correlation between the Endocan level and the permeability of EVLWI and PVPI was not observed.

**Conclusion** These results suggested that there was good relationship between the Endocan level and the severity of sepsis. But unlike the trauma patients, correlation between the severity of ARDS and Endocan value was not recognized.

**Mesenchymal stem cell and endothelial cell interaction restores endothelial permeability via paracrine hepatocyte growth factor in vitro**

Q Chen, A Liu, H Qiu, Y Yang

Southeast University, Nanjing, China

**Introduction** Mesenchymal stem cells (MSCs) have potent stabilizing effects on the vascular endothelium injury, inhibiting endothelial permeability in lung injury via paracrine hepatocyte growth factor (HGF). Recently, it has been indicated that MSCs secreted more factors by MSC–endothelial cell (MSC-EC) interaction. We hypothesized that MSC-EC interaction decreased endothelial permeability induced by lipopolysaccharide (LPS) via paracrine HGF.

**Methods** We investigated the endothelial permeability induced by LPS under two co-culture conditions in transwells. HPMECs were added into the upper chambers of cell-culture inserts, while two different co-culture conditions in the lower side of transwells as follows: MSC-EC interaction group: MSCs and HPMECs contact co-culture in the lower chambers and MSC groups: MSCs only in the lower chambers. The endothelial permeability in the upper side of transwells was detected. Then the concentration of HGF was measured in the culture medium using an enzyme-linked immunosorbent assay kit, followed by neutralizing HGF with anti-HGF antibody in the co-culture medium. In addition, VE-cadherin protein expression were measured under the co-culture conditions by western blot, adherens junctions (AJs) protein including F-actin and VE-cadherin were detected by immunofluorescence technique as well.

**Results** The permeability significantly increased after LPS stimulation in a dose-dependent and time-dependent manner (P < 0.01). Meanwhile, MSC-EC interaction more significantly decreased endothelial permeability induced by LPS (P < 0.05 or P < 0.01). Moreover, HGF levels in the MSC-EC interaction group were much higher than those of the MSC group (P < 0.01). However, neutralizing HGF with anti-HGF antibody inhibited the role of MSC-EC interaction in improving endothelial permeability (P < 0.05). Compared with the MSC group, MSC-EC interaction increased VE-cadherin protein expression (P < 0.01), and restored remodeling of F-actin and junctional localization of VE-cadherin. However, the MSC effect was significantly blocked by anti-HGF antibody (P < 0.05 or P < 0.01).

**Conclusion** These data suggest that MSC-EC interaction decreased endothelial permeability induced by LPS, which was mainly attributed to HGF secreted by hMSCs. The main mechanisms of HGF restoring the integrity of EC monolayers are remodeling of endothelial intercellular AJs and decreasing caveolin-1 protein expression.
admission to the SICU is associated with increased risk of new ARDS with a hazard ratio of 1.02 (95% CI: 1.01 to 1.02, P = 0.001) after adjustment for APACHE II score, age, gender, and chronic obstructive pulmonary disease.

**Conclusion** In surgical critically ill patients, active smokers are associated with increased risk of new ARDS, longer SICU LOS, and higher total ICU cost, compared with exsmokers and nonsmokers. Our findings emphasize the essential need for a smoking cessation program.

**Introduction** Traditionally, ARDS obese patients are ventilated with higher tidal volumes and higher PEEP due to expected increased in pleural pressure. However, data from the literature regarding the influence of body mass on lung mechanics and, particularly, on chest wall elastance are not univocal [1,2]. Failure to account for how the increase in body weight could affect the respiratory function can result in injurious mechanical ventilation and in the onset of VILI. The aim of this study was to evaluate the role of the body weight on respiratory mechanics in ARDS patients.

**Methods** A group of deeply sedated and paralyzed ARDS patients was divided into three classes according to the body mass index: normal weight (between 18.5 and 24.9 kg/m²), overweight (between 25.0 and 29.9 kg/m²) and obese (between 30.0 and 39.9 kg/m²). They were mechanically ventilated in volume-controlled mode with a tidal volume of 6 to 8 ml/kg according to predicted body weight. Respiratory mechanics and gas exchange were assessed at PEEP levels of 5 and 15 cmH₂O.

**Results** A total of 101 ARDS patients was enrolled; 44 (43.6%) patients were normal weight, 36 (35.6%) overweight and 21 (20.8%) obese. Lung and chest wall elastance were not different between groups, both at PEEP levels of 5 cmH₂O and 15 cmH₂O (P = 0.580 and 0.113, respectively), and the end-inspiratory transpulmonary pressure was also similar. We did not observe any difference between groups regarding PaO₂/FiO₂ ratio (P = 0.178 at PEEP 5 cmH₂O; P = 0.073 at PEEP 15 cmH₂O) and PaCO₂ (P = 0.491 at PEEP 5 cmH₂O; P = 0.237 at PEEP 15 cmH₂O).

**Conclusion** In ARDS obese patients the chest wall elastance and the end-inspiratory transpulmonary pressure are not affected by the body weight, suggesting that normal weight and obese patients present similar risks for lung stress and VILI onset. The severity of hypoxemia was not different between groups.

**References**
Methods The observational study in ICU ventilated septic patients with peritonitis (70%), pancreonecrosis (25%) and mediastinitis (5%) was done in 2010 and 2014. ARDS was diagnosed and staged according to the V.A. Negovsky Research Institute criteria and the Berlin definition. Plasma SPD was measured on ARDS diagnosis (day 0) and days 3 and 5 by the immunoenzyme essay (BioVendor, USA). Patients were treated according to the international guidelines. Data were statistically analyzed by STATISTICA 7.0, ANOVA and presented as median and 25 to 75th percentiles (ng/ml); \( P < 0.05 \) was considered statistically significant. Areas under the receiver operating curves were calculated.

Results Sixty-five patients (out of 450 screened) were enrolled in the study according to the inclusion/exclusion criteria. Patients were assigned into groups: NP + ARDS (\( n = 43, 43 \pm 4 \text{ years old}, \text{M/F} \ 39/4, \text{mortality} 23\% \) and NP (\( n = 22, 40 \pm 5.1 \text{ years old}, \text{M/F} \ 20/2, \text{mortality} 18\% \)). Groups were comparable in APACHE II and SOFA scores on the baseline. In the NP + ARDS group SPD was higher at all points than in the NP group. Plasma SPD on day 0 >111.2 ng/ml yielded a sensitivity of 68.2% and specificity of 92.3% (AUC 0.85; 95% CI 0.684 to 0.945; \( P < 0.0001 \)) for diagnosing ARDS in NP. P/F ratio on day 0 <280 yielded a sensitivity of 94.1% and specificity of 76.9% (AUC 0.85; 95% CI 0.744 to 0.952; \( P < 0.0001 \)) and EVLWI on day 0 >8.3 ml/kg yielded a sensitivity of 94.1% and specificity of 92.3% (AUC 0.92; 95% CI 0.801 to 0.982; \( P < 0.0001 \)) for the diagnosis of ARDS in NP. A complex ROC analysis (for SPD in the group of patients with P/F <280 and EVLWI >8.3) yielded a much better diagnostic accuracy of SPD: cutoff >93.7 ng/ml, sensitivity 81.0%, specificity 100.0% (AUC 0.96; 95% CI 0.817 to 0.998; \( P < 0.0001 \)).

Conclusion A complex approach (P/F <280, EVLWI >8.3, SPD >93.7) presents as a sensitive and highly specific method for diagnosing ARDS in NP patients.
demonstrated recently its effectiveness on prognosis. Extrapulmonary etiologies of ARDS include abdominal emergencies. In cases of severe hypoxemia in the early postoperative period, intensivists discuss prone positioning based on the risk/benefit ratio.

Methods We conducted a retrospective two-center study of 5 years. The aim was to compare the prevalence of surgical complication potentially related to prone positioning between patients who had at least one prone positioning session and patients that remained in a supine position after abdominal surgery. Patients with ARDS in a context of recent (<7 days) abdominal surgery (except laparoscopy) were included. The primary outcome was the number of patients who had at least one surgical complication potentially related to prone positioning. We defined a priori these complications: scar dehiscence, abdominal compartment syndrome, stoma leakage, stoma necrosis, scar necrosis, wound infection, displacing of a drainage system, removal of gastro- or jejunostomy feeding, digestive fistula, evisceration.

Results We identified 43 patients with postoperative ARDS (62 ± 8 years, SAPS II 50 ± 13), among whom 34 (79%) had emergent surgery. Fifteen patients had at least one stoma after surgery. Nineteen patients (44%) had at least one prone positioning session (number of sessions: 2 (1 to 3)). At baseline, prone group patients had minimal PaO2/FIO2 ratio lower than the supine group (77 ± 23 vs. 110 ± 46 mmHg, P = 0.005). Plateau pressure was higher in the prone group (28 ± 4 vs. 23 ± 5 cmH2O, P = 0.002). The first prone positioning session significantly increased the PaO2/FIO2 ratio: 106 ± 52 vs. 192 ± 90 mmHg (P = 0.001). Mean duration of the first prone positioning session was 20 ± 10 hours. In the prone group, 11 patients (58%) had at least one surgical complication, in comparison with nine (38%) in the supine group (P = 0.2). These complications resulted in revision surgery for two (10%) patients in the prone group and two (8%) in the supine group (P = 0.8). Mortality in the ICU was respectively 42% and 38% in prone group and supine group (P = 0.8).

Conclusion These preliminary results confirm the effectiveness of prone positioning in terms of oxygenation in ARDS after abdominal surgery without significant increase in surgical complications and no effect on the need for surgical revisions. Hence, if necessary, clinicians should not refrain from proning patients with postabdominal surgery ARDS.

Regional distribution of excess tissue mass in ARDS lung
I Algieri1, D Massari1, A Colombo1, G Babini1, F Crimella1, M Brioni1, A Cammaroto1, K Nikolla1, C Montaruli1, M Guanzirilli1, M Gotti1, C Chiurazzi1, M Amini1, M Chioldi1, M Cressoni1, D Chiumento1, L Gattinoni1
1Universita degli Studi di Milano, Milan, Italy; 2Regional IRCCS, Ospedale Maggiore Policlinico Mangiagalli Regina Elena di Milano, Milan, Italy Critical Care 2015, 19(Suppl 1):P244 (doi: 10.1186/cc14324)

Introduction ARDS is characterized by edema diffused to all lung fields. Distribution of excess tissue mass had been studied with CT scan in a few patients on a single slice, comparing with data obtained in healthy controls.

Methods ARDS patients underwent CT scan imaging during their ICU stay at 45 cmH2O end-inspiratory pressure. After hospital discharge, patients underwent a follow-up CT scan performed at end inspiration. Each lung was divided into three sections along the apex–base axis and into three sections along the sternum–vertebral axis (nine regions per lung). Excess tissue mass in each lung region was defined as the difference in lung tissue (grams) between the CT scan performed during ARDS course and the follow-up CT scan. Results are presented as mean ± SD.

Results We studied eight ARDS patients (55 ± 18 years) with a BMI of 27 ± 6 kg/m2. At ICU admission, patients had the following clinical parameters: PaO2/FIO2 106 ± 33 with PEEP 15 ± 5 cmH2O; PaCO2 43 ± 10 mmHg; pH 7.35 ± 0.05. The average increase in lung weight during ARDS compared with follow-up CT scan was 68 ± 40% (680 ± 320 g).

Figure 1 presents the tissue volume during ARDS (white bars) and after ARDS resolution (black bars) and compares the ratio between the two (*P < 0.01 vs. dependent region).

Conclusion The excess tissue mass was not different between apex, hilum and base, but was increased in the dependent lung regions at apex and hilum, being uniformly distributed at the lung base.
airway recruitment. This pilot study shows that, in ARDS, the upper lung regions are subject to airway dilation, whereas the lower (atelectatic) lung lobes have more airway opening with higher PEEP levels.

**Efficacy and safety of open lung ventilation in patients with impaired peripheral chemoreflex sensitivity**

N Trembach, I Zabolotskikh
Kuban State Medical University, Krasnodar, Russia

**Introduction** Mechanical ventilation during anesthesia leads to the development of atelectasis, poor oxygenation and postoperative pulmonary complications. Application of PEEP and recruitment maneuver (RM) can significantly reduce the severity of atelectasis and improve lung function. But the application of this strategy often leads to hemodynamic instability, which may be associated with impaired reactivity of the cardiovascular system. The purpose of this study was to evaluate the efficacy and safety of RM in patients with increased sensitivity of peripheral chemoreceptors (SPCR), which reflects the decreasing reactivity of the cardiovascular system.

**Methods** We conducted a prospective study in 116 patients with high SPCR, evaluated using the breath-holding test. The test was performed by measuring of voluntary breath-holding duration (BHD) after two-thirds of maximal inspiration. The end of breath-hold was determined by a palpation of contraction of the diaphragm. BHD <38 seconds was the marker of high SPCR [1]. All patients received a major abdominal surgery and were randomized into an open lung ventilation group or a PEEP group. The concept of open lung ventilation was performed as follows: PEEP was increased from 4 to 10 cmH2O for three breaths, from 10 to 15 cmH2O for three breaths, and from 15 to 20 cmH2O for 10 breaths [2]. Then PEEP was reduced to 12 cmH2O. This RM was repeated every hour. In the PEEP group PEEP was maintained at 12 cmH2O during the whole anesthesia. Hemodynamics, blood gases and dynamic compliance were evaluated.

**Results** RM improved oxygenation compared with the PEEP group. The mean increase in the oxygenation index at the end of surgery was 31% (from 340 to 445 mmHg, P <0.05), in the PEEP group the increase was less significant and amounted to 12% (from 330 to 370 mmHg, P <0.05). Dynamic compliance increased by 35% in the RM group and did not change in the PEEP group. Hemodynamic changes at RM were more pronounced. So CI on average decreased by 34% (from 3.7 to 2.5 l/minute/m2) compared with 10% with no RM (P <0.05), and SVR decreased by 19% (from 1,310 to 1,150 dyn x sec x cm-5, P <0.05), while in the PEEP group it did not change. No significant differences between groups in the incidence of complications, length of stay in the ICU and in the hospital were noted.

**Conclusion** RM patients with high SPCR and with reduced reactivity of the cardiovascular system improve lung function, but this is associated with the risk of hemodynamic instability.

**Determinants of energy dissipation in the respiratory system during mechanical ventilation**

D Massari, C Montaruli, M Gotti, C Chiurazzi, I Algieri, M Amini, M Broni, C Rovati, A Cammaroto, K Nikolla, M Guanzio, M Chioci, A Colombo, M Cressoni, L Gattinoni
Università degli Studi di Milano, Milan, Italy

**Introduction** Mechanical ventilation performs at each breath mechanical work on the lung parenchyma. Part of this energy is recovered and part is dissipated into the respiratory system. The purpose of this study is to assess the respective role of three known determinants of energy dissipation: lung opening and closing, strain and lung inhomogeneities [1].

**Methods** Thirteen female piglets (21 ± 2 kg) were ventilated with a strain (V/FRC) greater than 2.5 (V, ~ 38 ± 3 ml/kg) for 54 hours or until massive lung edema developed. Piglets were divided into five groups characterized by different energy loads obtained varying the respiratory rate: 15 breaths/minute (n = 3), 12 (n = 3), 9 (n = 3), 6 (n = 2) and 3 (n = 2). Every 6 hours two CT scans were performed (end-expiration and end-inspiration) and a static pressure–volume curve was obtained. A total of 51 CT scan couples and 51 corresponding pressure–volume curves was analyzed. The energy dissipated in the lung parenchyma at each breath was determined as the hysteresis area of the pressure–volume curve. CT scans were quantitatively analyzed with dedicated software. Data are presented as median (interquartile range).

**Results** Piglets ventilated with higher energy loads (RR 9, 6 and 3) developed ventilator-induced lung injury (VILI), while piglets ventilated with lower energy loads (RR 9, 6 and 3) did not. The energy dissipated in the lung parenchyma at each breath was 0.56 J (0.52 to 0.62). Dissipated energy increased with time in piglets that developed VILI, while it remained near-constant in all the other piglets. Recruittability was 6% (3 to 8) of lung parenchyma, strain was 3.1 (2.6 to 3.5) and lung inhomogeneity extent (that is, the percentage of lung parenchyma that is inhomogeneous) was 10% (9 to 11). The energy dissipated in the lung parenchyma was well related to lung recruitability (r = 0.57, P <0.0001) and lung inhomogeneity extent (r = 0.57, P <0.0001) and lung inhomogeneity extent (r = 0.57, P <0.0001). Multiple linear regression showed that dissipated energy was independently related to all of the three determinants of energy dissipation: lung opening and closing (P = 0.025), strain (P <0.0001) and lung inhomogeneities (P <0.01).

**Conclusion** Energy dissipation was largely dependent on strain, obtained with very high tidal volumes, but also lung inhomogeneities and lung opening and closing played a significant role.

**Immune response after prolonged hyperoxic mechanical ventilation**

HJ Helmerhorst, LR Schouten, NP Juffermans, MJ Schultz, E De Jonge, DJ Van Westerloo
1Leiden University Medical Center, Leiden, the Netherlands; 2Academic Medical Center, Amsterdam, the Netherlands

**Introduction** Mechanical ventilation and hypoxia independently promote pulmonary injury and inflammation. However, the time course of the immune response following concurrent exposure is unclear. The
Prolonged and severe hyperoxia caused an increase in inflammatory mediators independent of tidal volumes after 12 hours of MV. The presence of cytokines and chemokines in the pulmonary compartment was more pronounced in mechanically ventilated mice. The presence of cytokines and the immune response that was independent of tidal volumes in a model with prolonged and severe hyperoxia markedly influenced the effects of hyperoxia. See Figure 1.

Diff erences between the tidal volume groups were small and did not diff er between FiO₂ groups at 8 hours of ventilation. In mice ventilated for 12 hours, a signifi cantly increasing trend in IFNγ, IL-1β, IL-10, MCP-1 and TNFa was observed with increasing FiO₂ (P = 0.03). Cytokine and chemokine levels did not diff er between FiO₂ groups at 8 hours of ventilation. In mice ventilated for 12 hours, a significantly increasing trend in IFNγ, IL-1β, IL-10, MCP-1 and TNFa was observed with increasing FiO₂, whereas IL-6, KC, MIP-2, GM-CSF and VEGF remained virtually unchanged. Differences between the tidal volume groups were small and did not markedly influence the effects of hyperoxia. See Figure 1.

Conclusion Hyperoxia induced a time-dependent and diff erentiated immune response that was independent of tidal volumes in a model of mechanically ventilated mice. The presence of cytokines and chemokines in the pulmonary compartment was more pronounced with prolonged and severe hyperoxia.

Perioperative assessment of regional ventilation during changing body positions and ventilation conditions by electrical impedance tomography with increased spatial resolution and signal quality
A März1, A Ukere1, K Wodack1, C Trepte1, A Walldmann1, S Böhm2, D Reuter1
1University Medical Center Hamburg-Eppendorf, University Hamburg, Germany; 2Swisstom AG, Landquart, Switzerland

Introduction Electrical impedance tomography (EIT) is a functional imaging technology allowing one to regionally monitor aeration of the lungs. We used EIT with increased signal quality and spatial resolution to describe and quantify the regional changes in aeration caused by body position, both during spontaneous breathing and mechanical ventilation in pulmonary healthy patients undergoing laparoscopic prostatectomy.

Methods In 40 patients we performed EIT measurements at five points of time (Table 1) with the Swisstom BB2 prototype. Thirty-two electrodes were used to apply weak alternating currents to the thorax and to measure the resulting voltages, from which tomographic images of the changes in regional impedance caused by ventilation were created. We describe the ventilation distribution using a novel EIT lung function parameter called Silent Spaces that provides information about areas that do not receive much or any air during tidal breathing and are divided into nondependent (NSS) and dependent Silent Spaces (DSS) using a reference line that runs perpendicular to the gravity vector right through the centre of ventilation. NSS and DSS are expressed as a percentage of the total lung area.

Results Perioperative changes of NSS and DSS are shown in Table 1 as mean ± SD. Statistically signifi cant diff erences marked by § when compared with 1 or by * when compared with 3 (P < 0.05).

Conclusion We describe for the fi rst time the mapping of Silent Spaces during spontaneous breathing and changing ventilation conditions and body positions in patients with healthy lungs using EIT. This mapping of Silent Spaces might prove useful for developing perioperative protective ventilation strategies.

P250
Structural and functional effects of mechanical ventilation and aging on single rat diaphragm muscle fi bers
N Cacciani, H Ogilvie, L Larsson
Karolinska Institutet, Solna – Stockholm, Sweden

Introduction The still unclear mechanisms causing ventilator-induced diaphragm dysfunction (VIDD) are considered intrinsic to the diaphragm muscle fi bers. VIDD delays and complicates weaning from mechanical ventilation (MV) and accordingly contributes to prolonged ICU stay by 50%, with older patients being more affected than the young. The main aim of this study was to measure the effects of aging and 5 days of MV on rat diaphragm muscle fi ber structure and function. We also aimed to investigate the biological age of the old rats to obtain data useful to design future experimental studies focusing on the effects of age in an ICU setting.

Methods We used a unique ICU rat model, which allows us to maintain the vital parameters stable under deep sedation and MV for long durations (several weeks). Diaphragm fi ber cross-sectional area (CSA) and force-generating capacity (specifi c force = absolute force / CSA) were measured in young (6 months) and old (28 to 32 months) F344/BN hybrid rats in response to 5 days of deep sedation and volume-controlled MV. To investigate the biological age of the old rats, we performed a second set of experiments, comparing muscle fi ber CSA and specifi c force in fast and slow-twitch distal hind limb muscles in three diff erent age groups: young adults (6 months), middle aged (18 months) and old rats (28 months).

Results This study demonstrated an unexpected increase in CSA (P < 0.001) of the diaphragm fi bers in response to 5 days of MV in both young and old animals. Maximum force decreased 39.8 to 45.2% (P < 0.001) in both young and old animals compared with controls, resulting in a dramatic loss of specifi c force. This increase in CSA and the concomitant decrease in specifi c force observed in both young and old diaphragm fi bers are compatible with an ineffective compensatory hypertrophy in response to the MV. The comparison of the limb muscles

Figure 1 (abstract P248). Infl ammatory mediators independent of tidal volumes after 12 hours of MV.
fibers from young, middle aged and old animals confirmed the 28 to 32 month rats to be senescent from a skeletal muscle point of view. Conclusion These results demonstrate intrinsic changes in diaphragm muscle fibers of significant importance for the prolonged and complicated weaning from MV. Moreover, the increased number of frail diaphragm muscle fibers observed after MV in old age, both controls and mechanically ventilated, offers a further age-related possible mechanism which may be of significant clinical importance. These results also provided useful information to design future experimental studies focused on the effect of age in an ICU setting, pharmacological intervention strategies as well as mechanisms underlying rat strain differences.

P251
Does it make a difference to add automatic EPAP titration to the volume-targeted pressure support mode in noninvasive ventilation of hypercapnic ICU patients?
G Gursel, A Zerman, B Basarik, K Gonderen, M Aydogdu, S Memmedova
Gazi University Medical Faculty, Ankara, Turkey

Introduction Obese patients are increasing in number in ICUs and more than 90% of them also have sleep apneic syndrome. Variability in upper airway resistance during sleep and awakening periods makes it difficult to set EPAP in these patients. A new mode that automatically titrates EPAP according to upper airway resistance and IPAP according to target tidal volume may be more effective. The aim of this study is to evaluate whether adding automatic EPAP titration to the volume-targeted pressure support mode will provide any therapeutic advantages in hypercapnic ICU patients.

Methods The hypercapnic patients treated with average volume-assured pressure-support-automatic EPAP (AVAPS-AE) mode (Group 1 (G1)) were compared with those treated with AVAPS mode (Group 2 (G2)). G2 was recruited retrospectively and matched with G1 according to diagnoses, demographic characteristics, arterial blood gas values and daily noninvasive ventilation (NIV) usage times. Trilogy 100® devices and their software Directview® (Philips Respironics) were used to reveal the respiratory data such as pressures, volumes, and daily usage times. For statistical analyses, t test, chi-square test and repeated measures of ANOVA were used.

Results Twenty-eight patients were included in G1 and 22 patients in G2. There was no significant difference between the patients’ admission parameters and daily NIV usage times. PaCO2 decreased >5 mmHg in 93% of G1 patients and in 60% of G2 patients in the first 6 hours (P = 0.044). A 10 mmHg reduction in PaCO2 occurred in more patients (93% vs. 60%, P = 0.004) and in a shorter time (1.8 ± 1.2 vs. 3 ± 3 days, P = 0.044) in G1. At the time of discharge, PaCO2 levels were <50 mmHg in 79% of G1 vs. 41% of G2 patients (P = 0.006). Both groups showed similar and significant improvements in PaO2, PaCO2, and HCO3 levels within the first 4 days but only in G1 patients were HCO3 levels decreased more rapidly than G2 patients (P = 0.007). Duration of NIV (6 ± 2 vs. 8 ± 3 days, P = 0.002) and the number of mode and pressures changes (0.3 ± 1.8 vs. 2 ± 2 times, P > 0.0001) were significantly less in G1. While mean IPAP was similar in both groups, maximum and minimum EPAP titrated automatically in G1 were significantly different from G2. Mean tidal volume and amount of leakage were also significantly higher in G1.

Conclusion These results suggest that the AVAPS-AE mode may provide some advantages in hypercapnic ICU patients such as rapid PaCO2 reduction, less NIV duration and workload.

P252
Retrospective study of patients receiving long-term mechanical ventilation
IM Goodhart, MC Faulds, S Lobaz, AJ Glossop
Shefﬁ eld Teaching Hospitals NHS FT, Shefﬁ eld, UK

Introduction This study analysed the practice of clinicians managing patients requiring long-term mechanical ventilation in the critical care unit (CCU) of the Royal Cornwall Hospital, Truro (RCTH), comparing outcomes of primary tracheostomy (TR) with trial of extubation (TOE).

Methods All 89 inpatients on the CCU who received mechanical ventilation continuously for 7 days or more between October 2012 and December 2013 were initially included. Forty patients who were intubated prior to arrival at RCHT, had incomplete notes, or were extubated during end-of-life care were excluded. Patients were divided into groups by first airway intervention; 31 TOE, 18 TR.

Results A total 52% (16/31) of patients had TOE, required no other airway intervention and survived to discharge from hospital, compared with 72% (13/18) of TR patients. Four patients from each group failed a second airway intervention and died prior to a second intervention. In total, 8/11 patients who had a second intervention after failed TOE survived to discharge from hospital. One patient had a second TR but died before discharge. This gave an in-hospital mortality rate of 19% for the TOE group and 28% for the TR group. TOE was performed earlier, all 31 on days 7 to 15. TR was performed later; 14/18 on days 7 to 15, and 4/18 on days 17 to 23. Early TR was more successful; 11/11 survived to discharge without a second intervention who had TR on days 7 to 12, compared with 29% (2/7) after day 12. TOE was more successful when performed later; 64% (7/11) survived to discharge without a second airway intervention when TOE was after day 10, 45% (9/20) between days 7 and 10. After first failed TOE, four patients had a successful second TOE; all four survived to discharge resulting in a median CCU stay of 29 days and median hospital stay of 39 days (excluding prior to CCU admission). Seven patients had TR after the first failed TOE, five survived to discharge from the CCU and four to discharge from the hospital. This group had shorter median stays in both the CCU (27 days) and hospital (32 days). Overall, the median duration of time ventilated, in the CCU, and in hospital was shorter for the TOE group; 13, 17 and 24 days respectively, compared with 22, 27.5 and 34 days for the TR group.

Conclusion TOE is more common and is associated with shorter time spent ventilated, in the CCU and in hospital than TR. It is also associated with a lower in-hospital mortality rate. TOE is more successful when performed after day 10; TR is more successful when performed before day 13. After failed TOE, a second TOE is associated with longer time in hospital but a better mortality rate than secondary tracheostomy.
patients with pneumonia treated with NIV have the highest mortality. A low presenting pH is associated with a higher mortality in patients with pneumonia treated with NIV. However, in COPD patients, pH <7.25 is not associated with higher mortality in CC or 1 year. Further work defining the precise role of pH as a prognostic indicator is warranted.

Lung protective ventilation with lower tidal volumes and development of pulmonary complications in critically ill patients without ARDS
FD Simons1, A Serpa Neto2, M Gama de Abreu2, P Pelosi2, MJ Schultz3
1Academic Medical Center, Amsterdam, the Netherlands; 2Hospital Israelita Albert Einstein, São Paulo, Brazil; 3University Hospital Carl Gustav Carus, Dresden, Germany; 4IRCCS San Martino IST, Genoa, Italy

Introduction A large meta-analysis suggests that use of low tidal volumes benefits patients without ARDS [1] but most studies in this meta-analysis included patients receiving ventilation during general anesthesia for surgery. The aim of the present meta-analysis is to determine the association between tidal volume size and development of pulmonary complications in ICU patients.

Methods An individual patient data meta-analysis of studies of ventilation in ICU patients without ARDS. Corresponding authors of retrieved studies provided individual patient data. The primary outcome, pulmonary complications, was a composite of development of ARDS or pneumonia during hospital stay. Secondary outcomes included ICU and hospital length of stay, and in-hospital mortality. Patients were assigned to three groups based on tidal volume size (≤7 ml/kg predicted body weight (PBW), 7 to 10 ml/kg PBW, or ≥10 ml/kg PBW).

Results Seven investigations (2,184 patients) were meta-analyzed. Pulmonary complications occurred in 23%, 28% and 31% respectively in the ≤7 ml/kg PBW, 7 to 10 ml/kg PBW and ≥10 ml/kg PBW group (adjusted RR, 0.72; 95% CI, 0.52 to 0.98; P = 0.042). Occurrence of pulmonary complications was associated with a lower number of ICU-free days and alive at day 28, a lower number of hospital-free days and alive at day 28 and increased in-hospital mortality.

Conclusion Ventilation with low tidal volumes is associated with a lower risk of development of pulmonary complications. Occurrence of pulmonary complications is associated with an increased ICU and hospital length of stay and in-hospital mortality in ICU patients without ARDS.

Factors associated with survival and hospital discharge amongst critically ill patients undergoing prolonged mechanical ventilation in the North of England Critical Care Network
L O’Connor1, J Gonzalez2, L Garcia3
1San Gerardo Hospital, Monza, Italy; 2IRCC Ca’Granda Maggiore Policlinico Hospital, Milan, Italy

Introduction The combination of a global demographic shift and increased survival following critical illness has led to an increasing number of patients requiring prolonged mechanical ventilation (PMV) and longer critical care stay. This is a prospective observational study evaluating the characteristics and speciality-based outcome of critically ill patients undergoing prolonged mechanical ventilation in the North of England Critical Care Network (NoECCN).

Methods A weekly survey was conducted over a 1-year period screening patients older than 16 years of age requiring PMV in all 18 adult critical care units within the NoECCN. Patient data collected included patient demographics, admission diagnosis and speciality, hospital length of stay (LOS) pre and post critical care admission, severity of illness scores, critical care LOS and status at hospital discharge.

Results During the study period 134 patients met the criteria for PMV representing 1% of annual admissions and 6.9% NoECCN bed-days. The majority of patients receiving PMV were medical (50.7%), followed by emergency surgery (20.1%), elective surgery (16.4%) and specialist services such as spinal cord injury (8.2%) and cardiothoracic transplant (4.5%). The commonest admission diagnosis in the medical population was pulmonary infection followed by multi-system disorders, while 89.4% of surgical patients were admitted to critical care during the perioperative period. At the end of the study period the highest hospital mortality was observed in the nonspecialist surgical population (26.5%). In contrast, the medical population had one of the lowest hospital mortality rates (11.8%), lower than predicted using the intensive care national audit research network illness severity score. Comparable rates of hospital discharge were found in both medical (85%) and nonspecialist surgical patients (88.9%).

Conclusion The results of this study highlight an expanding proportion of NoECCN critical care bed-days occupied by stable patients undergoing PMV. In keeping with published UK data, elevated hospital mortality was observed in the nonspecialist surgical subpopulation. Although the literature suggests the medical cohort of patients has poorer prognosis, within our region all were liberated from mechanical ventilation and over 80% were discharged from hospital.

Effects of positive end-expiratory pressure on lung ventilation/perfusion matching: a clinical study
N Eronia1, T Mauri1, G Bellani1, R Marcolin1, S Marocco Arrigoni1, G Grasselli1, A Pesenti1
1San Gerardo Hospital, Monza, Italy; 2IRCC Ca’Granda Maggiore Policlinico Hospital, Milan, Italy

Introduction Positive end-expiratory pressure (PEEP) exerts multiple protective effects in hypoxemic critically ill patients: PEEP can increase end-expiratory lung volume (EELV) and induce recruitment, thus reducing lung strain and opening and closing of alveoli and potentially improving the ventilation/perfusion matching. In particular, estimation of PEEP-induced ventilation/perfusion matching might help identify the optimal PEEP setting, but bedside non-invasive methods are few and complex to be applied in daily clinical practice. Electrical impedance tomography (EIT) is a non-invasive bedside technique that claims to track global and regional changes in perfusion and ventilation over time. In the present study we aimed at verifying the effects of PEEP on ventilation/perfusion matching, as assessed by EIT, in acute respiratory failure patients.

Methods We enrolled 20 intubated critically ill patients undergoing controlled mechanical ventilation, sedated, paralyzed and with PaO$_2$/FiO$_2$ <300 at PEEP ≥5 cmH$_2$O. We started EIT monitoring (Pulmovista500®; Dräger Medical GmbH, Lübeck, Germany) and applied two PEEP levels (clinical and clinical + 5 cmH$_2$O) for 20 minutes each. We collected ventilatory and EIT parameters and, by offline analysis, we calculated the increase of EELV at higher PEEP and the EIT-based indexes of ventilation heterogeneity (VHeterod-insp) and of the regional homogeneity of ventilation/perfusion matching (HA/P).

Results Patients were 62 ± 12 years old, mean PaO$_2$/FiO$_2$ was 197 ± 52, lower PEEP level was 7 (7 to 9) cmH$_2$O, while higher PEEP was 12 (10 to 14) cmH$_2$O (P <0.001). At higher PEEP, EELV increased (391 (334 to 450) ml vs. PEEP low, considered as baseline, P <0.001); VHandr-insp was reduced (1.8 (1.5 to 2.4) vs. 2.2 (1.8 to 2.6), P <0.001) and HA/P increased (0.29 ± 0.19 vs. 0.2 ± 0.15, P <0.05). Interestingly, the increase of HA/P was significantly correlated with the decrease of VHandr-insp (r = −0.48, P <0.05). Moreover, patients with higher potential for improvement of ventilation/perfusion matching (that is, patients with increase of HA/P >16%) had higher baseline VHeterod-insp (2.6 (2.3 to 2.6) ml PBW).
4.8) vs. 1.9 (1.5 to 2.1), \( P < 0.01 \) and lower compliance of dependent lung regions (Crsdep, 13 ± 3 ml/cmH\(_2\)O vs. 18 ± 6 ml/cmH\(_2\)O, \( P < 0.05 \)), as compared with patients with smaller improvement.

**Conclusion** EIT might represent a feasible, bedside method to estimate PEEP-induced improvement in ventilation/perfusion matching. Assessing regional ventilation and mechanical lung properties might help identify patients who would benefit more from higher PEEP.

**P257**

18-FDG PET in lung transplantation  
I Aligieri, F Valenza, M Guanzoni, B Safaei Fakhr, M Cressoni, M Brioni, A Colombo, G Babini, D Massari, K Nikolla, G Crisafulli, S Paladin, L Rossa, A Falleschi, F Zito, D Chiurmeo, LGattinoni  
*Università degli Studi di Milano, Milan, Italy*  
*Fondazione IRCCS Ca’ Granda- Ospedale Maggiore Policlinico, Milan, Italy*

**Introduction** Lung transplantation is associated with an inflammatory reaction known as primary graft dysfunction. This clinical syndrome occurs within the first 72 hours after transplantation and is a sign of the graft dysfunction known as primary graft dysfunction. This clinical syndrome is characterized by hypoxemia (PaO\(_2/\)FiO\(_2\) < 300) and bilateral infiltrates that occur within the first 72 hours after transplantation and is a risk factor for graft failure.

**Methods** 18-FDG PET scan was used to study 15 lung transplantation patients. The rate of 18-FDG uptake (Ki) was computed voxel by voxel with the Patlak method. Patients were divided according to the median Ki (27.8 ± 20.3 to 34.6 ml/minute/ml × 10\(^4\)). Data are reported as median and interquartile range.

**Results** Five patients developed primary graft dysfunction; median Ki in these patients was not different from patients who did not (24.5 (18.2 to 33.6) ml/minute/ml × 10\(^4\)) vs. 29.2 (23 to 35.4) ml/minute/ml × 10\(^4\) respectively, \( P = 0.64 \). Bilateral lung transplantation patients were characterized by a median Ki of 30.5 (22.9 to 34.5) ml/minute/ml × 10\(^4\), while patients undergoing single-lung transplantation presented a median Ki of 24.4 (21 to 34.1) ml/minute/ml × 10\(^4\) (\( P = 0.06 \)). Considering single-lung transplantation, graft and native lung had similar Ki: 24.4 (21 to 34.1) ml/minute/ml × 10\(^4\) versus 24.2 (17.7 to 30.1) ml/minute/ml × 10\(^4\) respectively (\( P = 0.64 \)). When patients were divided according to the median Ki value, higher Ki was associated with more inflammation. **Conclusion** Patients clinically defined as having primary graft dysfunction did not have an increased rate of 18-FDG uptake. 18-FDG uptake was not different in single-lung versus bilateral transplantation and, in single-lung procedures, the native lung showed elevated inflammatory activity.

Usefulness of extravascular lung water assessment as a predictor of weaning from mechanical ventilation  
D Zelian, A Okasha, M Megahed, A Mahrous, R Mohamed  
Alexandria University Hospital, Alexandria, Egypt

**Introduction** Quantitative measurement of extravascular lung water (EVLW) would be extremely useful for clinical management, both as an index of severity and to guide treatment lung ultrasonography (LU) as a tool to quantify EVLW.

**Methods** Forty mechanically ventilated patients were examined for 5 successive days after being eligible for weaning; counting B-lines (comets) in both lung fields by LU, peak airway pressure, plateau airway pressure, static compliance and ABG analysis every 6 hours. Patients were divided into two groups according to success of the weaning process: group A (weaned group), and group B (nonweaned group).

**Results** The median value of LU comets was significantly lower in Group A compared with Group B. There was a significant increase in hypoxic index in Group A compared with Group B. There was no significant difference between both groups as regards PaO\(_2/\)FiO\(_2\), while Pplat showed a significant increase in Group B compared with Group A and C and showed a significant decrease in Group B.

**Conclusion** LU is a useful to quantify EVLW; it is a good predictor of weaning.

Pressure reconstruction method for spontaneous breathing effort monitoring  
N Damanhuri, YS Chiew, NA Othman, PD Docherty, GM Shaw, JG Chase  
1University of Canterbury, Christchurch, New Zealand; 2Christchurch Hospital, Christchurch, New Zealand

**Introduction** Estimating respiratory mechanics of mechanically ventilated patients is unreliable when patients exhibit spontaneous breathing (SB) efforts on top of ventilator support. This reverse triggering effect [1] results in an M-wave shaped pressure wave. A model-based method to reconstruct the affected airway pressure curve is presented to enable estimation of the true underlying respiratory mechanics of these patients.

**Methods** Airway pressure and flow data from 72 breaths of a pneumonia patient were used for proof of concept. A pressure wave reconstruction method fills parts of the missing area caused by SB efforts and reverse triggering by connecting the peak pressure and end-inspiration slope (Figure 1). A time-varying elastance model [2] was then used to identify underlying respiratory elastance (AUC\(_{Ea}\)). The area of the reconstructed M-wave has less pressure, resulting in a lower overall AUC\(_{Ea}\) without reconstruction. The missing area of the airway pressure or AUC\(_{Ea}\) is hypothesized to be a surrogate of patient-specific inspiratory to assess the strength of SB efforts. AUC\(_{Ea}\), and missing area A, are compared with without reconstruction.

**Results** Median AUC\(_{Ea}\) and breath-specific effort using reconstruction were 24.99 (IQR: 22.90 to 25.98) cmH\(_2\)O/l and 3.64 (IQR: 0.00 to 3.87)% versus AUC\(_{Ea}\) of 20.87 (IQR: 15.24 to 27.48) cmH\(_2\)O/l for unreconstructed M-wave data, indicating significant patient and breath-specific SB effort, and the expected higher elastance (\( P < 0.05 \)).

**Conclusion** A simple reconstruction method enables the real-time measurement of respiratory system properties of a SB patient and measures the surrogate of the SB effort, that latter of which has clinical use in deciding whether to extubate or re-sedate the patient.

**References**

Conclusion in extreme cases, can be up to 16%.

Results The coefficient of variation (CV) of identified Ers across all patients was low (<0.005), as expected, as the 30-minute period allows time-dependent alveolar recruitment to fully occur and stabilise. However, even with substantial stabilisation periods, there remains a difference between the minimum and maximum estimated Ers within each 1-minute period of analysed data. The differences were median 2.8% (interquartile range (IQR): 1.5 to 4.6%, 90% range (90R): 0.8 to 13.4%) for Ers and 3.6% (IQR: 2.3 to 5.2, 90R: 0.9 to 10.8) for Edynamic. Dynamic elastance (Edynamic = (peak airway pressure – positive end-expiratory pressure) / tidal volume) of the corresponding breathing cycle is calculated for comparison.

Reference

Introduction Model-based respiratory mechanics can be used to guide mechanical ventilation therapy. However, identified mechanical properties vary breath to breath, leading to potential treatment errors when using model-based care that requires accuracy. This study investigates and quantifies this variability to improve its application in guiding clinical interventions.

Methods Retrospective data from 12 acute respiratory distress syndrome (ARDS) patients were used [1]. Each patient was sedated to prevent spontaneous breathing effort, and ventilated using the volume control mode with a square flow profile. Varied PEEP levels were maintained for 30 minutes before 1 minute of data were collected for analysis. This dataset provides a wide range of respiratory mechanics values, and the clinical protocol detail is in [1]. A clinically proven, single compartment model model respiratory system elastance (Ers) is identified from data for every breathing cycle at each PEEP level using a linear regression method. The dynamic elastance (Edynamic) = (peak airway pressure – positive end-expiratory pressure) / tidal volume of the corresponding breathing cycle is calculated for comparison.

Results The patient-dedicated blood gas analysers demonstrated excellent agreement with the bench-top analyser for pH, pCO2, pO2 and K+, while Hct provides a reasonable trend monitor with variable bias. This indicates that scatter observed on the Hct sensor was largely due to inter-device rather than intra-device factors.

Conclusion The patient-dedicated blood gas analysers demonstrated excellent agreement with the bench-top analyser for pH, pCO2, pO2 and K+, while Hct provides a reasonable trend monitor with variable bias. Proxima is well suited to enable staff to more closely manage unstable and critically ill patients. This device may be of significant benefit to patients at risk of iatrogenic anaemia or those being treated in side rooms/isolation rooms.

**Tidal volume accuracy during non-invasive ventilation with modern neonatal mechanical ventilators**

K Moon, S Mazuykaka, K Tachibana, M Takeuchi
Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi City, Osaka, Japan

**Introduction**
Maintaining the appropriate tidal volume (VT) is important for success of lung protective ventilation. However, in neonates, the presence of airway leaks may increase the errors in the delivery of tiny VT, which raises a concern of ventilator-induced lung injury. This study is to investigate the accuracy of VT delivery during non-invasive ventilation (NIV) with modern neonatal ventilators.

**Methods**
Using a lung simulator for a patient body weight of 3 kg, we measured the actual delivered VT in the lung and compared it with the value displayed on the ventilator in six ventilators. We tested 18 conditions with various combinations of respiratory mechanics (normal, restrictive, obstructive), leak levels (0, 1.0, 1.5 l/minute), and PEEP settings (5, 10 cmH2O). All conditions were tested in NIV mode.

The pressure level was set to achieve VT to the lung at 6 to 7 ml/kg. All other settings were: FIO2 0.21, I时间 0.6 seconds, f 25/minute, and default rise time. We calculated the mean errors of the ventilator-displayed VT at various levels of airway leak.

**Results**
The VT mean error values are presented in Table 1. When no leak existed, the mean error was less than 5% in all ventilators except one (C3) which showed a mean error of 26%. As the leak level increased, three ventilators (C3, G5, and VNS500) showed marked differences between the delivered and displayed VT. In particular, the VNS500 could not operate in the large leak condition. The other three ventilators (PB840, PB980, Servo i) showed acceptable VT accuracy across all conditions tested.

Data presented as mean (SD), %. *Unable to measure in one case.

**Conclusion**
Tidal volume accuracy during neonatal NIV varies greatly among different ventilators and leak conditions. This must be considered in neonatal ventilation management to avoid over-ventilation or under-ventilation.

**Effective capnography training in the ICU using the ‘hats and caps’ training tool**

CA Lobo, FE Kelly, S Steynberg, G Thomas, C Pope, M Eveleigh, M Charlton, TM Cook
Royal United Hospital, Bath, UK

**Introduction**
Failure to use or correctly interpret capnography in patients dependent on an artificial airway in ICUs was thought to have contributed to 74% of ICU airway-related deaths in the NAP4 study [1]. However, capnography is only of value if those using it can interpret it correctly, with recommendations for training all ICU staff in capnography [1,2]. A recent UK survey identified that only 48% of ICUs have trained all staff in capnography interpretation (TM Cook, personal communication). In this study, we used a capnography teaching aid (‘hats and caps’) to educate all ICU staff during a 1-month period, and evaluated its effectiveness.

---

**Figure 1 (abstract P264).** ‘Hats and caps’ capnography training guide.
Methods ‘Hats and caps’ was devised on our ICU [3] and used for the training: this teaches that capnography traces on the left signify the airway is functional, in contrast to the traces on the right which indicate immediate attention is required (Figure 1). This was presented to staff working on the ICU in individual bedside teaching sessions with feedback obtained and evaluated.

Results We delivered teaching sessions to 100% (9/9) of junior doctors, 100% (71/71) of nursing staff and other health professionals. We obtained feedback from 90% (76/84), showing an improvement in understanding of capnography from 73% of respondents to 100%, with 87% reporting that the teaching aid made capnography interpretation much easier. All felt the training would improve patient safety, and 97% felt it would be worthwhile training in other ICUs.

Conclusion Use of ‘hats and caps’ enabled delivery of short bedside teaching sessions to clinical staff in ICU during everyday work. Feedback shows a marked improvement in confidence around capnography interpretation. It may have value in other ICUs to improve staff understanding of capnography and improve patient safety.

Comparison of three methods of applying high flow nasal oxygen: in vitro study

M Muñoz Garach1, O Olga1, ME Yuste Osorio1, R Fernandez Fernandez1, R Ramírez Puerta1, F Acosta Díaz1, AM Pérez Bailón1, S Narbona Galdó1, L Peñas Maldonado1
1Hospital Universitario San Cecilio, Granada, Spain; 2Hospital Nuestra Señora del Prado, Talavera de la Reina, Spain

Introduction High flow nasal (HFN) requires precise control of the fraction of inspired oxygen (FiO2) and flow contributed as well as an adequate adjustment of temperature and humidity of the gas provided. There are several equipments for HNF. We evaluated the FiO2 and flow measurements were performed at room temperature in the ICU of our hospital (23 to 26º). The data were processed using SPSS v.15.0.1, accepting a significance level of 95%.

Results The FiO2 variation –0.001 ± 0.09 (–0.01 to 0.002); FiO2 percentage variation –0.012 ± 1.88 (–0.27 to 0.25); r² = 0.999 and r = 0.998 (P <0.000). Flow variation (l/minute) 3.82 ± 3.85 (3.04 to 4.69); flow percentage variation 3.76 ± 8.08 (8.11 to 11.41); r = 0.969 and r² = 0.939 (P <0.000). (3) FiO2 variation –0.005 ± 0.26 (–0.001 to 0.000); FiO2 percentage variation –0.72 ± 5.2 (–1.5 to 0.1); r = 0.996 and r² = 0.992 (P <0.000). Flow variation (l/minute) 3.91 ± 1.26 (3.69 to 4.13); flow percentage variation 12.77 ± 5.33 (11.84 to 13.7); r = 0.996 and r² = 0.992 (P <0.000). See Figure 1.

Conclusion The FiO2 percentage variation in the Airvo® is higher than the other two devices, with no clinical relevance. The flow percentage variation of Evita XL® is superior to the other two devices; this may have some clinical relevance.

Surface electromyography of respiratory muscles during a CPAP trial for weaning

S Arigoni Marocco, G Bellani, A Bronco, M Pozzi, F Rabboni, G Villa, N Eronia, A Pesenti
San Gerardo Hospital, Monza, Italy

Introduction Weaning from mechanical ventilation is an important concern in ICU clinical practice. Surface electromyography (sEMG) [1] is a non-invasive tool to assess activity of different muscles. We describe sEMG patterns of respiratory muscles during a CPAP trial [2] in patients undergoing pressure support ventilation.

Methods Twenty-one adult and clinically stable patients undergoing assisted mechanical ventilation for more than 48 hours were investigated during pressure support (baseline) and during a 2-hour CPAP trial. sEMG of diaphragm (costmar), intercostal and sternocleidal (accessory muscles) was recorded with a dedicated device (Dipha16; Inbiolab, Groningen, the Netherlands) simultaneously with airway waveforms and expressed as the ratio of the signal during baseline. Diaphragmatic electrical activity from a nasogastric tube (EAdi) of 14 of those patients was also measured.

Results The rapid shallow breathing index was lower than 105 in all patients and only one patient failed the trial. We observed that the mean inspiratory costmar increased immediately after switch to CPAP but did not significantly vary during the CPAP trial (ANOVA, P = 0.7). On the other hand, the activation of accessory muscles increased significantly during the same period (P = 0.01) and was strongly correlated with respiratory rate (r = 0.41, P <0.001) and inversely with percentage variation −1.4040 ± 4.73 (–2.15 to −0.67); r = 0.996 and r² = 0.992 (P <0.000). Flow variation (l/minute) 3.82 ± 3.85 (3.04 to 4.69); flow percentage variation 3.76 ± 8.08 (8.11 to 11.41); r = 0.969 and r² = 0.939 (P <0.000). (3) FiO2 variation –0.005 ± 0.26 (–0.001 to 0.000); FiO2 percentage variation –0.72 ± 5.2 (–1.5 to 0.1); r = 0.996 and r² = 0.992 (P <0.000). Flow variation (l/minute) 3.91 ± 1.26 (3.69 to 4.13); flow percentage variation 12.77 ± 5.33 (11.84 to 13.7); r = 0.996 and r² = 0.992 (P <0.000). See Figure 1.

Conclusion The FiO2 percentage variation in the Airvo® is higher than the other two devices, with no clinical relevance. The flow percentage variation of Evita XL® is superior to the other two devices; this may have some clinical relevance.
A tight correlation between costmar and EAdi (tidal volume) was indicated by SEMG. Accessory muscles were progressively recruited and particularly in the conditions of increased respiratory rate and lower tidal volumes.

P267 Ventilator-day reductions not associated with reintubations and further reduced by an early mobilization program
M Palmquist-Tess, A Adams, J Mangan, D Owen, M LeClaire
HCWIC, Minneapolis, MN, USA

Introduction Mechanical ventilation is associated with increased risk of pneumonia, barotrauma, VILI, VAP, ARDS and mortality. From 2009 to 2014 in the MICU/SICU of our facility, efforts to reduce ventilator-days included: noninvasive ventilation, sedation reduction, daily sedation vacations and weaning protocols. In 2013, an early mobilization of ventilated patients in the SICU was initiated. Aggressive ventilator-day reduction efforts may be expected to lead to premature extubations and reintubations.

Methods Ventilator-day data were compiled from 2009 to 2014 for MICU and SICU in our facility. Reintubation rates were calculated when intubations were required >1 day after an extubation.

Results Ventilator volume ranged from 639 to 766 distinct patients/year in the MICU and from 555 to 687 for the SICU. Ventilator-day reduction was significant (P <0.01) for the MICU* (7.7 to 5.5%, -29%) and the SICU* (5.91 to 5.20, -12%). Reduction patterns differed between the units as the SICU had a distinct reduction (**P = 0.007) between 2012 and 2013 coinciding with implementation of an early mobilization program. Reintubation rates differed between the units and rates did not increase with decreasing mean patient ventilator-days. See Table 1.

* Significant as described in Results.

Conclusion Initiatives to reduce ventilator-days per patient realized significant reductions from 2009 to 2014 while reintubation rates were unaffected. One component of the bundle, early mobilization, introduced in the SICU in 2013 was associated with an additional reduction in mean ventilator-days.

P268 Open-label randomized control trial between low pressure support and T-piece method for discontinuation from mechanical ventilator and extubation in general surgical ICUs
K Chittawatanarat, S Orparin, S Orparin
Chiang Mai University, Chiang Mai, Thailand

Introduction In routine practice for most surgical patients in Thailand, all appropriated patients with planned discontinuation of mechanical ventilator (MV) are routinely changed to T-piece before extubation. However, this method needs to alter the instrument for testing tolerability of the patient. The objective of this study was to compare continuous low pressure support (PSV) and the T-piece method (T) before discontinue mechanical ventilation and extubation in the surgical intensive care unit (SICU).

Methods We performed a prospective open-label randomized control study (non-inferiority trial) in SICU patients who were intubated and used mechanical ventilation, and appropriated discontinuation of the ventilator between June 2011 and November 2013. All patients underwent the same weaning protocol. The appropriated patients for discontinuation of MV were randomized into low pressure support up to 7 cmH₂O and T-piece method. Reintubation within 72 hours, pneumonia after extubation, and hospital mortality were recorded. The statistical significant difference was considered when P <0.05.

Results A total of 520 patients were randomized into two groups: low pressure support group (260 patients) and T-piece group (260 patients). There was no difference in age, gender, body mass index, comorbidity, site of surgery, Charlson Comorbidity Index and Acute Physiologic and Chronic Health II score between groups (P >0.05). Regarding the intention to treat analysis, there were no differences between groups in reintubation rate (PSV 10% vs. T 14.6%; P = 0.109), pneumonia after extubation (PSV 14.2% vs. T 11.9%; P = 0.435) and hospital mortality rate (PSV 3.1% vs. T 3.5%; P = 0.805).

Conclusion The outcomes after discontinuation of the mechanical ventilator between low pressure support and T-piece was not different after group in term of reintubation, pneumonia after extubation and hospital mortality.

P269 Systematic procedures including non-invasive ventilation improve morbidity in sleeve gastrectomy
I Auriant, N Devos, S Rossi
Clinique de l’Europe, Rouen, France

Introduction Postoperative morbidity after sleeve gastrectomy is decreasing, but remains significant. Bleeding and surgical fistulas remain the leading causes of morbidity and mortality. In several studies in postoperative care of obese patients, non-invasive positive pressure ventilation (NPPV) reduced the risk of lower respiratory tract infection and pneumonia [1], thereby reducing in-hospital morbidity. The aim of study was to describe whether systematic use of NPPV improves morbidity in the postoperative care of sleeve gastrectomy.

Methods A 4-year before–after study was conducted in a 19-bed intermediate care unit of a private hospital. Before period: standard treatment – all patients received oxygen supplementation to achieve SaO₂ above 90%. After period: standard treatment plus NPPV – all patients were submitted to a systematic postoperative protocol: NPPV was provided using an oxygen CIPAP system with 5 cmH₂O. Statistical analysis: complication rates were compared using the chi-square test. P <0.05 was considered statistically significant.

Results A total of 857 patients were included. Inclusion characteristics were similar in the two groups: Before group – non-NPPV: 352 patients, 2010 to 2011. Age: 40.58 ± 10.94, BMI: 42.79 ± 5.51, sex ratio F/M: 0.81. After group – NPPV: 504 patients, 2012 to 2013. Age: 40.81 ± 11.24, BMI: 42.92 ± 5.09, sex ratio F/M: 0.77. There is a significant between-group difference in the complication rate: Before group – no-NPPV: 10 surgical fistula (2.84%) and six postoperative bleeding (1.70%); After group – NPPV: seven surgical fistula (1.39%) and three postoperative bleeding (0.6%). The overall complication rate fell from 4.54% to 1.96%. The chi-square statistic = 4.58. The number of degrees of freedom is 1. The value returned from the chi-square statistic is P <,5.<%

Conclusion Systematic use of NPPV significantly improves morbidity in the postoperative care of sleeve gastrectomy.

Early postoperative pulmonary complications following heart transplantation
A Camkiran Firat, O Komuccu, P Zeyneloglu, M Turket, A Sezgin, A Pirat
Baskent University, Ankara, Turkey

Introduction The aim of this study was to determine the types, incidence, and risk factors for early postoperative pulmonary complications in heart transplantation recipients.

Methods We retrospectively collected data from the records of consecutive heart transplantsations from January 2003 to December 2013. A total of 83 patients underwent heart transplantation. Those patients younger than 10 years (n = 9) and the patients who died intraoperatively (n = 1) or during the first postoperative day (n = 1) were not included in the analyses. The data collected for each case were demographic features, duration of mechanical ventilation, respiratory problems that developed during the ICU stay, and early postoperative mortality (<30 days). The respiratory complications that we sought were pleural effusion, pneumonia, pulmonary atelectasis, pulmonary edema, pneumothorax, and acute respiratory failure.

Results Of the 72 patients considered, 52 (72.2%) were male. The mean age at the time of transplantation was 32.1 ± 16.6 years. The mean duration of postoperative mechanical ventilation was 71.8 ± 126.6 hours. The mean length of ICU stay was 13.5 ± 18.0 days. Two patients (2.8%) and one patient (1.4%) required extracorporeal membrane oxygenation support and intra-aortic balloon pump support, respectively, due to low cardiac output or primary graft failure postoperatively. Twenty-five patients (34.7%) developed early postoperative respiratory complications. The most frequent problem was pleural effusion (n = 19, 26.4%) followed by atelectasis (n = 6, 8.3%), acute respiratory distress syndrome (n = 5, 6.9%), pulmonary edema (n = 4, 5.6%), and pneumonia (n = 3, 4.2%). Postoperative duration of mechanical ventilation (44.2 ± 59.2 hours vs. 123.8 ± 190.8 hours, P = 0.005) and the length of ICU stay postoperatively (10.1 ± 5.8 hours vs. 19.8 ± 28.9 hours, P = 0.03) were longer among patients who had respiratory problems. Postoperative length of stay in the hospital (22.3 ± 12.5 days vs. 30.3 ± 38.3 days, P = 0.75) was similar in the two groups. The overall mortality rate was 12.5% (n = 9 patients). The patients who had respiratory problems did not show higher mortality than those who did not have respiratory problems (16.0% vs. 10.6%, P = 0.71).

Conclusion Respiratory complications were relatively common in our cohort of heart transplant recipients. However, these complications were mostly self-limiting and did not result in increased mortality.

Systematic alveolar recruitment after cardiac surgery
AL Lafarge, CK Kerneis, F Scalbert, LL Larrier, AB Brusset, PE Estagnasie,
PS Squara
Clinique Ambroise Paré, Neuilly-sur-Seine, France

Introduction We designed a pilot study to evaluate the interest of an early systematic acute recruitment maneuver (ARM) in postcardiac surgery hypoxemic patients in order to properly design a larger trial.

Methods This randomized controlled trial included consecutive patients operated on in our institution. Three hours after surgery, hypoxemic patients (PaO2/FIO2 <300 mmHg, FIO2 = 1) were randomly assigned to ARM or control (H0). ARM was performed by applying once a positive end-expiratory pressure of 35 cmH2O during 45 seconds.

Results We included 124 patients, age 67.5 ± 10.6 years, M/F sex ratio 95/29, left ventricle ejection fraction 58.8 ± 10.6%, forced expiratory volume 94 ± 23% of the predicted value, bypass/valve ratio 82/53. The preoperative and postoperative PaO2/FIO2 were 401 ± 66 and 204 ± 66 mmHg, respectively (P <0.0001). The hemodynamic and ventilation status as well as the fluid and inotrope supports were comparable in the two groups. At H1, PaO2/FIO2 was 367 ± 15 in the recruited group versus 299 ± 15 mmHg in the control group, P = 0.002. At H8 and 24 the difference was not significant. At H48, the PaO2/FIO2 was lower in the recruited group (296 ± 10 vs. 343 ± 11 mmHg, P = 0.003) (Figure 1). The duration of mechanical ventilation (invasive + non-invasive) was lower in the recruited group (total 6.4 ± 1.4 vs. 8.4 ± 1.4 hours, P = 0.02). The survival rate, the length of stay in the ICU and the occurrence of pneumonia were similar in the two groups (P >0.2).

Conclusion We can speculate that the inverse evolution of the blood oxygenation between the ARM group versus control may be due to: barotraumatism of normal alveoli during the ARM and/or a higher de-recruitment rate after ARM due to the shorter mechanical ventilation support. This pilot study shows that a unique ARM decreased the duration of MV in cardiac surgery patients but this may have subsequent detrimental effects on blood oxygenation.

P272
Is procalcitonin a valuable marker for identification of postoperative complications after coronary artery bypass graft surgery with cardiopulmonary bypass? A Baysal1, M Dogukan1, H Toman1
1Kartal Kouyolu Research and Training Hospital, Istanbul, Turkey; 2Adiyaman University Research and Training Hospital, Adiyaman, Turkey; 3Canakkale 18 Mart University Hospital, Canakkale, Turkey

Introduction The aim of our study was to investigate the value of C-reactive protein (CRP) and procalcitonin (PCT) in identification of the systemic inflammatory response syndrome (SIRS) and other complications in the early postoperative period after cardiac surgery with cardiopulmonary bypass (CPB) [1].

Methods In 93 patients undergoing coronary artery bypass graft surgery with CPB, after Ethical Committee approval in a prospective study, serum PCT and CRP values were collected before operation and daily until postoperative day 5. All patients were divided post hoc into patients with SIRS (n = 42) and patients without SIRS (n = 51). Student’s t test, the Mann–Whitney U test and receiver operating characteristic (ROC) curves were used.

Results The comparison of serum CRP values in patients with or without SIRS on postoperative day 1 until postoperative day 5 demonstrated an increase in both groups without significant differences (P >0.05). The PCT levels increased more significantly in SIRS patients (5.78 ± 3.21 ng/ml vs. 1.23 ± 0.31 ng/ml) compared with patients without SIRS (P = 0.0001) on postoperative day 1. In patients with postoperative complications (21/93, 22%) (circulatory failure = 10, pneumonia = 2, respiratory insufficiency = 9, sepsis = 0), PCT levels remained elevated until postoperative day 5 (6.11 ± 2.87 ng/ml) but diminished in patients with SIRS (0.96 ± 0.23 ng/ml) (P <0.0001). A PCT threshold value of 2.79 ng/ml was able to discriminate between postoperative complications in patients with or without SIRS with a sensitivity of...
82.5% and a specificity of 70% (area under the curve: 0.76 ± 0.05; P <0.01) on postoperative day 1.

Conclusion After cardiac surgery with CPB, PCT values increased significantly in the SIRS group of patients, compared with patients without SIRS on postoperative day 1 and remained elevated until postoperative day 5. In the early postoperative period, early rise of PCT values may help to discriminate the development of postoperative complications in patients with or without SIRS.

P273 Prediction of risk factors related to the development of hepatic dysfunction following open heart surgery
A Baysal1, I Ozkaynak2, M Dogukan3
1Kartal Kouyoulu Research and Training Hospital, Istanbul, Turkey; 2Kahramanmaras Sütçü İymam University Hospital, Kahramanmaras, Turkey; 3Adiyaman University Research and Training Hospital, Adiyaman, Turkey

Introduction Our goal was to investigate the incidence of postoperative jaundice in open heart surgery patients and to determine the risk factors associated with hepatic dysfunction.

Methods A total of 292 patients were included in a prospective study design. Patients undergoing on-pump coronary artery bypass graft surgery (CABG) (n = 154) and valve repair surgery (mitral, mitral and aortic valve and/or tricuspid valve) (n = 138) were included. Postoperative hyperbilirubinemia was defined as occurrence of a plasma total bilirubin concentration of more than 34 μmol/l (2 mg/dl) in any measurement during the postoperative period. All patients were divided into groups with or without hyperbilirubinemia. Liver enzymes were collected on postoperative days 1, 7, 14 and 30. The risk factors including age, cardiopulmonary bypass time, number of blood transfusions, inotropic support, use of intra-aortic balloon pump and ICU stay were evaluated with logistic regression.

Results Postoperative hyperbilirubinemia was observed in 27 of 292 patients (9.3%). The numbers of valves replaced, preoperative total bilirubin concentration, increased cardiopulmonary bypass time, higher number of inotropic support agents, and use of intra-aortic balloon pump correlate with hyperbilirubinemia on postoperative day 7 (P <0.05). Independent risk factors of early postoperative jaundice are: multiple valve replacement surgery, ejection fraction and use of intraaortic balloon pump (R = 0.58, R² = 0.33, F = 26.44, P <0.001). The ICU stay was significantly longer in group 2 (11.52 ± 3.76 days) as compared with group 1 (2.79 ± 1.36 days) (P <0.001).

Conclusion Patients undergoing multiple valve replacement procedures are at greater risk for the development of postoperative hyperbilirubinemia and an association with prolonged ICU stay was observed. Other risk factors including ejection fraction, increased cardiopulmonary bypass time and use of intra-aortic balloon pump are also important as they have been reported to increase postoperative complications [1].

P274 Determinants of gas exchange during extracorporeal CO2 removal using a novel pump-driven venovenous gas exchange system in a minimally invasive setting
A Hermann, K Riss, P Schellongowski, A Bojic, P Wohlfarth, O Robak, W Sperr, T Staudinger
Medical University of Vienna, Austria

Introduction Pump-driven venovenous extracorporeal CO2 removal (ECO2-R) increasingly takes root in hypercapnic lung failure to minimize ventilation invasiveness or to avoid intubation. A recently developed miniaturized device consisting of a centrifugal pump and a membrane ventilator (iLA Active®; Novalung, Germany) allows effective decarboxylation via a jugular double lumen cannula. So far no data on gas exchange in this setting exist to date.

Methods We included 10 patients receiving iLA Active® due to hypercapnic respiratory failure as bridge-to-transplant or obstructive lung disease. Sweep gas flow was increased in steps from 1 to 14 l/minute at constant blood flow (phase 1). Similarly, blood flow was gradually increased at constant sweep gas flow (phase 2). At each step, gas transfer via the membrane as well as arterial blood gas samples were obtained.

Results During phase 1, we observed a significant increase in CO2 transfer together with a decrease in PaCO2 levels from a median of 66 mmHg (range 46 to 85) to 49 (31 to 65) mmHg from 1 to 14 l/minute sweep gas flow, while arterial oxygenation deteriorated with high sweep gas flow rates. During phase 2, oxygen transfer significantly increased leading to an increase in PaO2 from 67 (49 to 87) at 0.5 l/minute sweep gas flow to 117 (66 to 305) mmHg at 2.0 l/minute. Higher blood flow rates also significantly enhanced decarboxylation. Increasing blood flow to 2.0 l/minute led to negative suction pressures of more than –100 mmHg and signs of hemolysis. See Figure 1.

Conclusion Increasing sweep gas flow results in effective CO2 removal which can be further reinforced by raising blood flow. The clinically relevant oxygenation effect even in this setting of low invasivity could broaden the range of indications towards hypercapnic lung failure with mild to moderate hypoxia.

P275 Safety and efficacy of extracorporeal CO2 removal combined with continuous renal replacement therapy in patients presenting both acute respiratory distress syndrome and acute kidney injury
J Allardet-Servent, M Castanier, T Signouret, A Lepidi, R Soundaravelou, J Sieghbyoan
Hôpital Européen Marseille, France

Introduction Pulmonary overdistension has been observed in 33% of patients with acute respiratory distress syndrome (ARDS) despite low tidal volume (6 ml/kg ideal body weight) ventilation [1]. Tidal volume
(VT) reduction from 6 to 4 ml/kg attenuates overdistension but is associated with hypercarbia [2]. We thought to combine extracorporeal CO2 removal (ECCO2R) with continuous renal replacement therapy (CRRT) through the insertion of an oxygenator membrane within the hemofiltration circuit in patients presenting both ARDS and acute kidney injury (AKI).

Methods A first set of measurement was performed at 6 ml/kg before and after ECCO2R. Twenty minutes later, VT was reduced to 4 ml/kg for the remainder of the study period (72 hours). Ventilator settings were thoracic. The CRRT mode was hemofiltration with 33% of predilution. Ultrafiltration was adjusted to achieve a filtration fraction of 15%. Sweep gas flow was constant at 8 l/minute. The primary endpoint was a 20% reduction of PaCO2 at 20 minutes after initiation of ECCO2R.

Results Eight patients were studied. Age was 69 ± 11 years, SAPS II was 68 ± 9 and SOFA score was 13 ± 4 at inclusion. Blood flow, at the inlet of the oxygenator membrane, was 400 ± 4 ml/minute. CO2 removal rate was 84 ± 4 ml/minute. Initiating ECCO2R, at 6 ml/kg, induced a mean PaCO2 reduction of 17% (41.5 ± 5.5 to 33.9 ± 5.6 mmHg, P < 0.001). Then, lowering the VT to 4 ml/kg induced a mean PaCO2 increase of 25% (33.9 ± 5.6 to 42.6 ± 8 mmHg) and a mean PaO2/FIO2 ratio increase of 8% (176 ± 63 to 190 ± 61). Minute ventilation decrease from 7.4 ± 1.6 to 5 ± 1.2 l/minute. Respiratory system compliance did not vary. No major complications occurred.

Conclusion Combining ECCO2R and CRRT in patients with ARDS and AKI is safe and feasible through the insertion of an oxygenator membrane within a RRT circuit.

Interhospital transfer of patients in extracorporeal membrane oxygenation
F Socci, S Di Valvasone, M Ciapetti, A Franci, M Bonizzoli, G Cianchi, S Batacchi, A Peris
Careggi Hospital, Florence, Italy

Introduction The transfer of patients in extracorporeal membrane oxygenation (ECMO) from a peripheral hospital to a tertiary center represents a high-risk situation of adverse events [1]. The aim of this retrospective study is to determine the feasibility and safety of interhospital transfer for critically ill patients with ECMO support.

Methods We collected data for the ECMO Regional Reference Centre Careggi Hospital activity from September 2009 to June 2014. In this study, 57 transfers were examined. The ECMO service is activated by a telephone call from a peripheral hospital. The team is represented by an intensivist, a heart surgeon, a cardiologist, a perfusionist and an intensive care nurse, all previously trained in the management of patients with ECMO. Medical personnel and the necessary equipment are transported by an ambulance and a van, specially designed and equipped for the transfer of patients with ECMO.

Results In this study, 57 patients transferred from the peripheral hospital to the ECMO center were examined; in all cases the ECMO system was implanted in the peripheral hospital (54 venovenous ECMO and three venaarterious ECMO). On average, trails were 271 km ± 304 (round trip) (minimum 14 km to maximum 939 km). The activation time from the call to the ambulance departure from our hospital was an average of 2 hours 27 minutes 13 seconds ± 1 hour 25 minutes 35 seconds. Transfer duration (from activation to return to the ECMO center) was an average of 8 hours 25 minutes 6 seconds ± 3 hours 27 minutes 58 seconds (minimum 3 hours to maximum 16 hours 55 minutes). The stop time (necessary for evaluation of the patient and for placement of the ECMO system) was an average of 3 hours 53 minutes 40 seconds ± 1 hour 6 minutes 35 seconds (minimum 2 hours 5 minutes to maximum 7 hours 30 minutes). Major complications related to malfunctions of the devices during transport were not recorded; in some cases it was necessary to manage minor complications (circuit cavitation, minor vascula accesses bleeding).

Conclusion Some studies have found several complications during transfer of patients in ECMO [2]. In our experience, there were no complications during the transfer of ECMO patients, even for longer trips. A wide and thorough clinical evaluation and multidisciplinary ECMO team allowed the optimization of clinical parameters before transport and a safely transfer. The start of ECMO treatment at peripheral hospital and the transfer of patients in ECMO may be a viable option compared with conventional ventilation. Our data suggest that ECMO can be set up safely in peripheral hospitals by a multidisciplinary highly specialized ECMO team [3].

Differential venous oxygen return: a key factor of differential hypoxia in venoarterial extracorporeal membrane oxygenation
X Hou1, X Yang1, Z Du1, J Xing1, C Jiang1, J Wang1, Z Xing1, H Wang1, H Zeng2
1Beijing Anzhen Hospital, Beijing, China; 2Beijing Key Laboratory of Emerging Infectious Diseases, Beijing, China

Introduction Differential hypoxia is a pivotal problem in cardio-pulmonary failure patients with femoral venoarterial extracorporeal membrane oxygenation (VA ECMO) support. Although there was some attempt to deliver more oxygenated blood to the upper body, the mechanism of differential hypoxia has not been well investigated.

Methods We used a sheep model of acute respiratory failure that was supported with femoral VA ECMO (from inferior vena cava to femoral artery (IVC-FA), ECMO from IVC to carotid artery (IVC-CA) and ECMO adding an additional return cannula to internal jugular vein based on femoral VA ECMO (FA-IJV). Angiography and blood gas analysis were performed.

Results Blood oxygen saturation (SO2) of IVC (83.6 ± 0.8%) was higher than that of SVC (40.3 ± 1.0%) in sheep with IVC-FA. Oxygen-rich blood was drained back to the ECMO circuit and poorly oxygenated blood in the SVC entered the right atrium (RA). SVC-FA achieved the oxygen-rich blood return from IVC to RA without shifting the arterial cannulation. SO2 of SVC and pulmonary artery increased (70.4 ± 1.0% and 73.4 ± 1.1%, respectively) subsequently. Compared with IVC-FA, less differences of venous oxygen return and attenuated differential hypoxia were also observed in IVC-CA and FA-IJV. See Figure 1.

Conclusion Differential venous oxygen return is a key factor of differential hypoxia in VA ECMO. We can take advantage of the notion of differential venous oxygen return to choose better cannula configuration in clinical practice.

Successful approach for emergent consent for ECMO research
J Board1, S Vallance1, C Aubron2, D Pilcher1, V Pellegrino1, DJ Cooper1
1The Alfred Hospital, Melbourne, Australia; 2Monash University, Melbourne, Australia

Introduction The HELP-ECMO pilot study (Heparin low dose protocol versus standard care in critically ill patients undergoing ECMO; ACTRN12613001324707) is a randomised controlled phase II study evaluating two levels of heparin anticoagulation in patients with no requirement for full anticoagulation. This work is a substudy of the HELP-ECMO trial and describes the consent process of the parent study. At our site, consent for research is often obtained by the research coordinator with little involvement from investigators. However, the nature of the ECMO population required a modified consent approach to be implemented given that ECMO is often inserted emergently. It required a model that would be successful out of hours and could be delivered by any member of the treating team.

Figure 1 (abstract P278). SO2 values from blood gas analysis and vena cava angiography.
Methods The HELP-ECMO pilot study is enrolling patients admitted to a large metropolitan ICU who require ECMO. Education on eligibility criteria and study processes was given to all ICU senior medical staff. Consent must be performed prior to the commencement of anticoagulation, often only a short time after ECMO cannulation. To facilitate recruitment at all hours, a HELP-ECMO study box is located in the ICU. Within the box is an instruction page outlining the screening, consent and randomisation process, as well as administrative tasks. Plain language statements, randomisation envelopes and consent documentation stickers are provided. A consent script is provided to ensure consistency across consenting personnel. The process is reviewed by the research coordinator the following day to confirm local governance compliance.

Results From April to December 2014, 30 patients were screened. Fourteen met the eligibility criteria and were approached for consent. Twelve patients were enrolled and randomised to receive either standard anticoagulation or low-dose heparin as per the study protocol. Consent was provided by the person responsible for 10 patients. One patient was competent to consent for themselves and one was enrolled under legislation allowing enrolment into research in the absence of a person responsible. There were two refusals. Seventy-one per cent of participants were approached out of hours. Eighty-six per cent were consented by clinicians. Twenty-one per cent of patients were consented by a non-investigator.

Conclusion The model of consent described has proven to be successful in this challenging patient population. The ability of all staff to perform consent for the study has been a significant factor in the success of the pilot. The review of study processes by research coordinators has supported this model.

P280 Extracorporeal membrane oxygenator and ventricular assist device activity of a tertiary cardiothoracic centre: survival rates and length of ITU stay

D Samdou1, CP Walker1, N Rashid1, D Heaton1, I McGovern1, N Marczin2, J Mitchell3

1 The Royal Brompton & Harefield NHS Foundation Trust, London, UK; 2 Imperial College, London, UK; 3 The Royal Brompton & Harefield NHS Foundation Trust, London, UK

Introduction Harefield Hospital accepts patients as a tertiary centre for end-stage heart and respiratory failure for the south of England. Interventions include VA-ECMO, VV-ECMO as a bridge to lung transplantation, left ventricular assist devices (LVAD) as a bridge for heart transplantation, right ventricular assist devices (RVAD) and BIVADs. The aim of this review was to identify the total number of such patients, analyse the individual length of ITU stay and calculate survival and mortality rates for each intervention.

Methods Patients consisted of six groups: Group 1: VA ECMO, Group 2: VV-ECMO, Group 3: LVAD, Group 4: RVAD, Group 5: BIVAD, Group 6: combination of devices. Data were extracted from the Perfusion Department records and the intensive care dataset from 2011 to 2013. Data included length of ITU stay, outcome, indication for device insertion and device-related major complications.

Results Forty patients were identified. Twenty-nine were male and 11 female. Group 1 included 22 patients, Group 2: two patients, Group 3: four patients, Group 4: four patients, Group 5: zero, Group 6: eight patients treated with various combinations of ECMO or ventricular assist devices. ITU stay varied from 1 day to a maximum of 6 months intermittently for one patient. Duration of ITU stay for all 40 patients was 1,052 days with an average of 26.3 days per patient. Sixteen patients survived and were discharged to the Transplant Unit. Twenty-four patients died, putting the survival rate at 40% for this group.

Conclusion This review demonstrates that the majority of these patients occupied intensive care beds for a prolonged period of time and despite the use of advanced support devices survival rates were significantly lower than mortality rates.

P281 In-hospital and long-term mortality after venoarterial ECMO for refractory cardiogenic shock

M Bottiroli, F Maraffi, D Decarli, S Nonini, E Montrasio, K Gervasio, F Milazzo, R Paino

Anesthesia Rianimazione 3, A.O. Niguarda, Milan, Italy

Introduction Venoarterial (VA) ECMO is used for mechanical support in patients with cardiogenic shock (CS) unresponsive to medical therapy. Long-term survival and quality of life after hospital discharge have not yet been well analyzed.

Methods We performed a retrospective observational study of patients admitted to the ICU for refractory CS from January 2010 to November 2014. Patients with postcardiotomy and/or post-transplant CS were excluded. Demographic, clinical and biochemical variables were collected. Continuous variables are presented as mean (standard deviation) and categorical variables as percentage. Long-term outcome and quality of life were assessed during scheduled follow-up evaluations or telephonic interviews.

Results We analyzed 23 consecutive patients undergoing VA ECMO for refractory CS. Etiologies of cardiac collapse were: 11 acute myocarditis, five acute myocardial infarctions and seven acute decompensation of chronic cardiomyopathies (CCM). Thirteen patients died during the hospital stay and 10 survived. The main cause of ICU death was progressive multiple organ dysfunction (12/13). Baseline variables are presented in Table 1. All patients discharged from the hospital are still alive at follow-up (median 27 months, range 4 to 56) with a median NYHA class of 1 (range 1 to 2). All patients except one returned to an active style of life. Multivariate analysis (Cox) revealed pre-ECMO SOFA score (HR = 2.18, 95% CI = 1.016 to 4.6) and history of CCM (HR = 19, 95% CI = 2 to 178) and pre-ECMO lactate (HR = 1.2, 95% CI = 1.02 to 1.4) as independent risk factors for hospital mortality.

Conclusion VA-ECMO is an effective treatment tool for refractory CS in patients with acute life-threatening heart failure. Patients affected by acute decompensation of CCM had poorer outcomes characterized by multiple organ dysfunction, as already known in the literature.

P282 Characteristics of trauma patients with creatinine kinase elevation

N Assanangkornchai, O Akaborworn, C Tongkamol, K Kaevaenggrueang

Prince of Songkla University, Hatyai, Thailand

Introduction Rhabdomyolysis is a condition that results in the release of mainly creatine kinase (CK) and myoglobin from the breakdown of myocytes. Myoglobin has been known to cause renal failure (RF) and the CK level is routinely used as an indicator. A CK level >5,000 U/l was found to be associated with the risk of RF [1]. However, data are lacking on the level of CK to predict RF, especially in general trauma patients. The purpose of this study was to determine the initial CK level that predicts markedly elevated CK and the characteristics of trauma patients with elevated CK.
Methods Data from the Songklanagarind Hospital trauma registry were reviewed over 1 year (January 2013 to December 2013). Patients with at least two records of CK and creatinine (Cr) levels were included. Creatinine kinase levels were analyzed during the first 3 days of hospital admission. RF was defined as a Cr increment >0.3 mg/dl within 48 hours. Results Of the 1,491 patients admitted to the trauma service, 47 patients had CK levels drawn twice. These patients had a mean age of 32 years and a median Injury Severity Score (ISS) of 14. The predominant mechanism of injury was motorcycle crash. Only three patients developed RF. The median CK during the first 3 days after admission was 3,088 (IQR 1,327, 6,072) U/l. The CK peaked at 11 hours after admission at a mean value of 16,114.167 (SD 34,010.80) U/l. There were no significant differences in demographic data, ISS scores and fluid balance between the groups of CK level over or below 5,000 U/l. A mean positive fluid balance observed; however, initial CK was significantly different between the two groups. None of the patients with initial CK of <900 U/l had a peak of CK >5,000 U/l.

Conclusion Trauma patients had varying levels of elevated CK. Initial CK shows a promising result as a predictor of high peak CK levels. A larger sample size is needed to demonstrate the predictors of RF in trauma patients with elevated CK levels.

P283 Rhabdomyolysis: early prognostication of renal failure and other adverse outcomes
J Simpson, A Taylor, DK Menon, N Sudhan, A Lavinio
University of Cambridge, UK ‘Cambridge University Hospitals, Cambridge, UK

Introduction The clinical diagnosis of rhabdomyolysis is confirmed by creatine kinase (CK) levels >1,000 IU/l [1]. A local therapeutic protocol triggers aggressive renoprotective treatment in all patients with CK >2,000 IU/l. To evaluate local practice and refine CK thresholds for the instigation of renoprotective treatment, we studied the correlation between CK time trends and adverse outcomes such as acute kidney injury (AKI), the need for emergency renal replacement therapy (RRT) and mortality. We also evaluated the McMahon Score, a risk prediction model based on demographic, clinical, and laboratory variables available on admission [2].

Methods A retrospective observational study of adults with confirmed rhabdomyolysis admitted to the Neurosciences Critical Care Unit between 2002 and 2012. Data collection included APACHE score, daily CK (with PEAK CK defined as the maximum CK recorded throughout ICU stay), creatinine, calcium, phosphate and bicarbonate levels, AKI, RRT, ICU length of stay and mortality.

Results A total of 232 patients met the inclusion criteria. Rhabdomyolysis was associated with trauma (76%), medical (15%) and surgical (9%) admission diagnoses. Forty-five (19%) patients developed AKI, with 29 (12.5%) requiring RRT. Mortality was significantly higher in patients who developed AKI (62% vs. 18%, P <0.001). Average CK on admission was 5,009 IU/l (SD 12,403 IU/l). CK values remained greater than 2,000 IU/l for an average of 3.3 days (range 1 to 10 days). Although PEAK CK was greater in patients requiring RRT compared with those that did not (PEAK CK: 32,354 IU/l vs. 7,353 IU/l, P = 0.001), receiver operating characteristic curves revealed that a threshold for PEAK CK >5,000 IU/l is only 55% specific and 83% sensitive for the prediction of need for RRT. CK peaks on the day of admission in 46% of patients, on day 2 in 37%, and on day 3 or later in 17% of cases. A McMahon Score >6 calculated on admission is 68% specific and 86% sensitive for RRT.

Conclusion Although higher CK levels are associated with adverse outcomes, instigation of renoprotective treatment should not be based solely on CK levels. A McMahon Score >6 on admission allows for a more sensitive, specific and timely identification of patients at risk of renal failure requiring RRT.

Results Table 1 presents the performance of the models and admission pNGAL. Performance improved when predictions were made at a later time point, and was highest for LR_BAD1. Similar results were obtained in subgroups of septic and cardiac surgery patients. As an independent predictor, pNGAL alone did not perform better than a model using routine clinical data available upon admission. However, when combining pNGAL with LR_BA, predictive performance improved. The performance of LR_BAD1 was not improved by including pNGAL.

Conclusion This study shows the potential of data-driven models based on routinely collected patient information for early detection of AKI during the first week of ICU stay. Although adding admission pNGAL to admission data improved early detection of AKI, this added value is lost upon inclusion of data from the first day of ICU.

P286 Is acute kidney injury in the early phase of sepsis a sign of metabolic downregulation in tubular epithelial cells?
K Jin, H Li, J Volpe, D Emlet, N Pastor-Soler, MR Pinsky, BS Zuckerbraun, K Hallows, JA Kellum, H Gomez
University of Pittsburgh, PA, USA

Introduction This study tested the hypothesis that the cellular response in the kidney to sepsis is characterized by early activation of AMPK activated protein kinase (AMPK), and that such activation is temporally associated with downregulation of the epithelial sodium channel (B-ENaC).

Methods Fifteen C57BL/6 wildtype (WT) mice were subjected to cecal ligation and puncture (CLP), and sacrificed at 2, 6, 18, 24, or 48 hours. In addition, we pretreated three WT and three AMPK Beta 1 knockout mice with the AMPK activator AICAR (100 mg/kg intraperitoneal, 24 hours before CLP), and sacrificed 24 hours after CLP. Blood and tissue samples were collected for all animals. AMPK activation (pThr172), B-ENaC, and mitophagy (LC3 II/I) were examined by western blot of kidney lysates. Plasma creatinine (Scr) was assessed using ELISA.

Results The acute response to sepsis was characterized by early activation of AMPK which increased from 6 to 18 hours, peaked at 24 hours, and decreased by 48 hours (Figure 1A). This activation was associated with a consistent decrease in B-ENaC expression. In AICAR pretreated animals, AMPK was only activated in WT mice, which was associated with a decrease in the expression of B-ENaC as compared with AMPK KO mice (Figure 1B).

Conclusion AMPK was activated early after induction of sepsis, and was associated with a consistent decrease in Beta-ENaC expression in the apical membrane of tubular epithelial cells. In addition, absence of AMPK activation in KO animals was associated with increased expression of Beta-ENaC at 24 hours after CLP. These data support the hypothesis that early activation of AMPK decreases energy consumption through ion channel downregulation.

P287 Urinary TIMP-2 and IGFBP7 elevate early in critically ill postoperative patients that develop AKI
P Honore1, LS Chauwla2, A Bihorac3, AD Shaw4, J Shi5, JA Kellum6
1VUB, Brussels, Belgium; 2VAMC, Washington, DC, USA; 3UF, Gainesville, FL, USA; 4VUSM, Nashville, TN, USA; 5WB, Carlsbad, CA, USA; 6PiU, Pittsburgh, PA, USA

Introduction Little is known about temporal changes in [TIMP-2·IGFBP7] relative to injury in patients who develop AKI. In this analysis, we examined [TIMP-2·IGFBP7] in serial urine collections from the subset of Sapphire patients who were admitted to the ICU after major surgery.

Methods We stratified 238 Sapphire patients into three groups by their maximum AKI stage within 48 hours of the start of surgery using KDIGO criteria (No AKI, KDIGO 1, and KDIGO 2 to 3). Median TIMP-2·IGFBP7 values were calculated from all samples collected at 12 (±6)-hour intervals for 4 days following the start of surgery.
Results There were 101 patients without AKI, 95 patients with KDIGO 1 AKI, and 42 patients with KDIGO 2 to 3 AKI within 48 hours of the start of surgery. In patients without AKI, median TIMP-2*IGFBP7 values were less than 0.3 (ng/ml)²/1,000 (dashed line in Figure 1) for all time points. In patients with KDIGO 1 AKI, median (TIMP-2*IGFBP7)² significantly exceeded this cutoff at 24 and 36 hours following the start of surgery (*one-sided γ < 0.025). Median (TIMP-2*IGFBP7)² increased earlier in KDIGO 2 to 3 AKI patients, remaining significantly elevated relative to the cutoff from 12 to 60 hours after the start of surgery. The highest median (TIMP-2*IGFBP7)² was observed at 24 hours for KDIGO 2 to 3 AKI patients and was nearly five times the 0.3 (ng/ml)²/1,000 cutoff.

Conclusion Urinary (TIMP-2*IGFBP7)² was significantly elevated as early as 12 to 24 hours from the start of surgery in patients who developed AKI within 48 hours. Monitoring of these biomarkers in the immediate postsurgical period might enable improved management of patients at risk for AKI.

P288 Urinary TIMP2 and IGFBP7 as early biomarkers of acute kidney injury in septic and nonseptic critically ill patients
M Cuartero1, A Betbesé1, J Sabater1, J Ballús1, J Ordóñez1
1Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona, Spain; 2Hospital Universitari Bellvitge, Hospitalet Llobregat, Barcelona, Spain

Introduction Sepsis and acute kidney injury (AKI) have a high prevalence in the ICU population. The aim of this study is to describe the composite of tissue inhibitor of metalloproteinas-2 (TIMP2) and insulin-like growth factor-binding protein-7 (IGFBP7) as novel urinary renal biomarkers in both septic and nonseptic patients.

Methods We conducted a prospective, observational study in two university hospitals. Patients were admitted in ICU either from the emergency department or after undergoing an acute surgery at hospital admission. Two months prior to the admission, recruited patients had not been admitted to hospital. We collected epidemiological, clinical and laboratory data at admission, 24 and 48 hours. TIMP2*IGFBP7 was analysed in urine samples by a point-of-care device (Nephrocheck®; Astute Medical).

Results The sample included 98 patients (65 men) with mean age 55 ± 17.3 years, length of ICU stay 11.1 ± 14.6 days. In total, 41.4% had sepsis at ICU admission; 59.2% were diagnosed of sepsis within the first 48 hours of stay. We stratified patients based on the presence of AKI as per the AKIN KDIGO definition, as well as their worst level of TIMP2*IGFBP7 during their first 2-day stay. Values of mean and 25th to 75th percentile for the worst value of TIMP2*IGFBP7 were 0.24 (0.11 to 0.46), 0.50 (0.28 to 1.24), 0.94 (0.34 to 3.28) and 3.34 (1.47 to 6.22) for no AKI, AKIN I, II and II respectively (P < 0.0001). The worst values for no AKI/no sepsis, no AKI/sepsis, AKI/no sepsis and AKI/sepsis were 0.21 (0.10 to 0.4), 0.32 (0.15 to 0.63), 1.05 (0.41 to 2.31) and 0.98 (0.36 to 3.94) respectively, with P < 0.05 for AKI and P = NS for sepsis. The AUC ROC curve for prediction of AKI of the worst value was 0.80 with sensitivity of 73.5% and specificity of 71.4% (P < 0.0001). In contrast to the Sapphire study, in our population cutoff values of 0.4 and 0.8 (ng/ml)²/1,000 predict AKI and AKIN ≥II respectively, regardless of the presence of sepsis. See Figure 1.

Conclusion TIMP-2 and IGFBP-7 can predict AKI in both septic and nonseptic critically ill patients. Further pragmatic randomised controlled trials are needed to prove their role on clinical basis.

P289 Single point measurement of cystatin C has similar performance as serum creatinine for assessment of kidney function in critically ill patients
J Houthoofd1, M Carlier1, J De Waele1, R Vanholder2, J Delanghe2, J Decruyenaere2, E Hoste2
1OLV Van Lourdes Hospital, Waregem, Belgium; 2Ghent University Hospital, Ghent, Belgium

Introduction The gold standard for routine evaluation of kidney function is measurement of serum creatinine concentration (Scr). In ICU patients, muscle loss and dilution leads to decreased Scr. Scr is distributed in total body water, resulting in delay of Scr changes when the glomerular filtration rate (GFR) changes (lag time). Cystatin C (CysC) is a protein produced by all cells with a nucleus and therefore less affected by muscle mass. Also, the lag time may be shorter as the volume of distribution is only extracellular fluid. The objective of this study was to evaluate whether single point measurement of CysC in ICU patients is more adequate than Scr for monitoring of kidney function in ICU patients.

Methods Data were collected in two prospective single-center studies on a convenience sample of ICU patients. During the 24-hour study period, we measured CysC, Scr, and urinary inulin clearance (Cinu) as a
gold standard for assessment of GFR. We compared Scr and CysC, with Cinu. Also, we assessed Cinu in patients who had CysC and Scr within the normal sex and age corrected limits. Finally, we determined the ability of CysC and Scr to detect normal range and decreased GFR (80 to 120 ml/minute/1.73 m² resp. <60).

**Results**
We included 68 patients, with median age 58 years (IQR 29 years), length of stay in the hospital before study 11 days (IQR 16), and APACHE II score 19 (IQR 9). Scr was 1.12 (IQR 1.55), CysC 0.64 (IQR 0.73), and Cinu 80 ml/minute/1.73 m² (IQR 82). Scr was markedly decreased in patients with Scr in normal range (n = 12) compared with patients with Cinu in normal range (n = 22) (55 ml/minute/1.73 m² (IQR 57.4) vs. 100 (IQR 42.2), P < 0.001). Patients with normal range Scr had similar proportion of patients with Cinu in the normal range compared with normal range CysC patients (33.3% vs. 45.5%, P = 0.23).

ROC analysis showed that Scr and CysC had similar performance for detection of normal range Cinu (AUC: 0.66; 95% CI = 0.53 to 0.77 vs. 0.77; 95% CI = 0.65 to 0.87; P = 0.116), and decreased Cinu (AUC: 0.86; 95% CI = 0.76 to 0.97 vs. 0.94; 95% CI = 0.88 to 1; P = 0.113).

**Conclusion**
Single point measurement of Scr and CysC has similar performance for detection of normal and decreased GFR in this cohort of ICU patients. Performance was weak for detection of normal GFR, but both biomarkers had moderate good performance for detection of decreased GFR.

Early prediction of acute kidney injury after transcatheter aortic valve implantation with urinary G1 cell cycle arrest biomarkers

University Hospital Essen, Germany

**Introduction**
Acute kidney injury (AKI) is a common complication following transcatheter aortic valve implantation (TAVI) and has been shown to increase mortality. The concentration of the G1 cell cycle arrest proteins TIMP-2 and IGFBP7 in the urine have recently been suggested as sensitive biomarkers for early detection of AKI in critically ill patients. Whether postoperatively elevated levels of urinary TIMP-2*IGFBP7* (UTI) predict the development of an AKI in patients undergoing TAVI is currently unknown.

**Methods**
In a prospective cohort study, 40 patients undergoing TAVI, either trans-apical (TA) or trans-aortic (T Ao), were enrolled. Serial measurements of UTI were performed every 12 hours in the postoperative course. Results were calculated for their multiplication and presented as arbitrary values. Urinary output and serum creatinine were recorded simultaneously. The primary clinical endpoint was the occurrence of AKI according to the AKI Network.

**Results**
Mean age was 81 ± 5.6 years (16 male, 40.0%). Thirty-five patients underwent TA-TAVI and five patients TAo-TAVI. AKI developed in 17 patients (42.5%); seven patients (17.5%) suffered from AKI 3 and required renal replacement therapy (RRT). Mean maximum value of UTI within 24 hours after TAVI was significantly higher in patients with AKI compared with patients without renal impairment (2.19 ± 3.11 vs. 0.67 ± 0.18, P = 0.037) and higher in patients with AKI 3 compared with patients with AKI 2 (4.73 ± 3.58 vs. 0.59 ± 0.71, P = 0.022). In contrast, preoperative creatinine (AKI (mg/dl) 1.22 ± 0.41 vs. no AKI 1.30 ± 0.59; AKI 3 1.32 ± 0.49 vs. AKI 2 1.26 ± 0.53, P = NS) and early postoperative serum creatinine levels (maximum within 24 hours after TAVI: AKI 1.41 ± 0.50 vs. no AKI 1.34 ± 0.60; AKI 3 1.69 ± 0.56 vs. AKI 2 1.32 ± 0.54, P = NS) did not show any association with the development of AKI. ROC analyses revealed a very good predictive value of early UTI levels for the development of AKI 3 within the next 72 hours after TAVI with a sensitivity of 100% and a specificity of 80% for a cutoff value of 0.815 (AUC = 0.919, 95% CI = 0.824 to 1.0, SE 0.048, P = 0.001).

**Conclusion**
Early elevation of urinary TIMP-2*IGFBP7* after TAVI is associated with the development of postoperative AKI. These biomarkers have an excellent diagnostic accuracy in the prediction of severe AKI requiring RRT that is superior to that of serum creatinine. Further studies are necessary to prove whether UTI-guided therapy of patients with AKI can reduce morbidity and mortality.

Association between urinary TIMP-2 and IGFBP7 as early biomarkers of AKI and oliguria during liver surgery: a prospective pilot study

F. Desmet, M. D’Honda, H. Potel, S. Carlier, E. Hoste, J. Kellum, W. De Corte
1AZ Groeninge, Kortrijk, Belgium; 2Catholic University Leuven, Kortrijk, Belgium; 3Ghent University Hospital, Ghent University, Ghent, Belgium; 4University of Pittsburgh School of Medicine, Pittsburgh, PA, USA

**Introduction**
Patients undergoing elective liver surgery have an increased risk for developing AKI [1]. This study was intended to assess TIMP-2*IGFBP7* and its possible association with urine output (UO) in this population. Secondly we sought to compare TIMP-2*IGFBP7* with serum creatinine concentration (Scr).

**Methods**
A prospective single-center pilot study performed on 12 patients undergoing elective liver surgery. Serial urine samples were analyzed for TIMP-2*IGFBP7* measured with the Nephrocheck device (Astute Medical, San Diego, CA, USA). Serial Scr was analyzed, UO, blood losses, and mean arterial pressure (MAP) were recorded. Fluid management was standardized, oliguria defined as a UO <0.5 ml/kg/hour. TIMP-2*IGFBP7* values of >0.3 identify patients at high risk and >2 at highest risk for AKI [2].

**Results**
Males comprised 66.7%, median age was 72 years. Median surgical time was 195 minutes. Peroperative median MAP was 71 mmHg (IQR 69; 77). Baseline median GFR was normal in eight patients and decreased in four patients (eGFR >90 and 66.5 ml/minute/1.73 m² respectively). Median baseline Scr was 0.75 mg/dl (IQR 0.61; 1.10), 0.74 mg/dl (IQR 0.64; 1.04) at ICU admission and 0.74 mg/dl (0.64; 1.04) on day 1 postoperatively. No difference in Scr and eGFR was seen between these time points (P = 0.457 and P = 0.517 respectively; repeated-measures ANOVA). Median peroperative and postoperative UO was 0.18 ml/kg/hour (IQR 0.13; 0.23) and 0.93 ml/kg/hour (IQR 0.79; 1.49) respectively. Median baseline TIMP-2*IGFBP7* was 0.10 (IQR 0.04; 0.34), 0.22 (1.44; 6.23) during surgery, 0.61 (IQR 0.27; 1.22) at ICU admission and 0.74 (0.67; 0.97) on day 1 postoperatively. TIMP-2*IGFBP7* differed at these time points (P <0.0001; repeated-measures ANOVA). Peroperative oliguria was associated with increased TIMP-2*IGFBP7* (P = 0.018, chi-squared test).

**Conclusion**
This pilot study demonstrated the association between TIMP-2*IGFBP7* increase and oliguria and may therefore indicate kidney damage during liver surgery. As Scr could not differentiate for these changes, patients did not meet the classical biomarker criteria for AKI.

Continuous infusion of low-dose iohexol confirms 1-hour creatinine clearance is more accurate in acute kidney injury than 4-hour creatinine clearance: preliminary data

J. Dixon1, K. Lane1, R. Dalton1, J. MacPhee1, B. Phillips1
1St George’s Hospital and University of London, UK; 2King’s College, London, UK

**Introduction**
There is currently no accurate method of measuring the glomerular filtration rate (GFR) during acute kidney injury (AKI). Four-hour creatinine clearance (4-CrCl) is often used. We have previously validated a method of measuring the GFR using a continuous infusion of low-dose iohexol (CILDI) in patients with stable renal function (GFR from normal to <30 ml/minute/1.73 m²). Steady state was achieved in <10 hours in all subjects and we calculate that variations >10.3% suggest an AKI. In this study we compare GFR measured by CILDI with 4-CrCl and 1-hour creatinine clearance (1-CrCl).

**Methods**
Critically ill patients with evolving AKI and patients following nephrectomy were recruited. Demographics were compared using the t test. CILDI was connected for up to 72 hours. Plasma and renal iohexol and creatinine concentrations were measured by tandem mass spectrometry four times daily. Iohexol renal clearance (IRC) and

Does cardiopulmonary bypass increase the risk of postoperative acute kidney injury after coronary artery bypass grafting?

A Karmali, C Walker, L Kuppurao
Harefield Hospital, London, UK

Introduction Acute kidney injury (AKI) following coronary artery bypass grafting (CABG) results in significant morbidity, mortality and prolonged stay on the cardiothoracic ICU. We sought to determine the incidence of AKI in our cardiothoracic centre, hypothesizing a higher occurrence in patients undergoing CABG using cardiopulmonary bypass (OPCAB) compared with off-pump (OPCAB) surgery [1].

Methods Retrospective data from all non-implanted patients undergoing isolated CABG at our institution were collected for the year 2013. Propensity scoring using the software platform MatchIt® was used to match subjects from ONCAB and OPCAB groups with regard to preoperative variables: logistic EuroSCORE, creatinine clearance (CrCl), gender and operative urgency. Postoperative AKI was defined as a rise of 50% or more in baseline serum creatinine [2]. Chi-square analysis was used to determine statistically significant differences.

Results From 500 cases (369 OPCAB, 131 ONCAB), 262 subjects were included in the final analysis, with 131 in each group. There was a higher incidence of AKI in our cardiothoracic centre, hypothesizing a higher occurrence in patients undergoing CABG using cardiopulmonary bypass (ONCAB) compared with off-pump (OPCAB) surgery [1].

Conclusion Our study is limited by its size and the use of logistic EuroSCORE as a composite measure of risk factors. However, it has demonstrated that in our predominantly off-pump cardiac unit, OPCAB conferred no statistically significant advantage over ONCAB with regard to postoperative AKI. Studies to date have standardised patient-specific variables, but not the conduct of the procedure itself; for example, minimising renal hypoperfusion during OPCAB. This may be a reason for the lack of clear superiority in the continuing debate over choice of CABG procedure and reducing the risk of AKI.

Impact of kidney injury on fluid overload and impaired oxygenation

A Akcan Anikan, LL Loftis, WA Arnold, CE Kennedy
Baylor College of Medicine, Houston, TX, USA

Introduction Severity of acute kidney injury (AKI) and fluid overload (FO) are not incorporated into current severity of illness measures and are invisible to the practitioner. The causal relationship and timing between AKI and FO and oxygenation is not clear. The Fluid Overload Kidney Injury Score (FOKIS) is a daily score incorporating subscores for AKI (pRIFLE (creatinine (Cr) and urine output (UOP)), FO (total fluid (in – out) / ICU admission weight) >15% in five percentile increments, and exposure to nephrotoxic medications. We previously reported that FOKIS outperforms PRISM in mortality prediction in our pediatric intensive care unit (PICU). We hypothesized that patients with AKI on admission to the PICU developed worse fluid overload and in turn worse oxygenation.

Methods We prospectively calculated daily FOKIS scores and subscores (Cr, UOP, FO) in PICU patients. We excluded patients with <7 day stays in order to properly explore the association between timing of AKI and FO and oxygenation by oxygenation index (OI).

Results Over 18 months, there were 2,830 patients, 436 patients with PICU stay >7 days, 361 patients had complete data for all 7 days. Mortality was 4.5% overall and 11% cohort. A total of 246 patients (68%) had AKI (by FOKIS cr or FOKIS uop); 205 patients (57%) on day 1, 85 patients (24%) on day 3. Admission or day 3 AKI by either FOKIS subscore (FOKIS cr or FOKIS uop) did not predict maxFO or mortality. Increasing total FOKIS score was associated with increasing mortality and increasing OI (Table 1). FOKIS, controlled for PRISM, was an independent predictor of OI (P = 0.03).

Conclusion In PICU patients, admission or day 3 AKI alone did not predict maxFO. A composite score that includes both AKI and FO parameters correlated with OI and discriminated survivors from nonsurvivors. FO seems to result from combination of increased fluid exposure with underlying AKI but cannot fully be explained by oliguria in pediatric patients.

Acute kidney injury biomarkers offer the opportunity to reduce exposure to nephrotoxic drugs

M Ostermann, L Fornier, K Kashani, M Joannidis, A Shaw, M Chawla, JA Kellum*, on behalf of the Sapphire Investigators
1Guy’s & St Thomas Foundation Hospital, London, UK; 2Royal Surrey County Hospital, Guilford, UK; 3Mayo Clinic, Rochester, MN, USA; 4University Hospital Innsbruck, Austria; 5Vanderbilt University Hospital, Nashville, TN, USA; 6George Washington University Medical Center, Washington, DC, USA; 7University of Pittsburgh, PA, USA

Introduction Tissue inhibitor of metalloproteinase-2 (TIMP-2) and insulin-like growth factor binding protein 7 (IGFBP7) are specific urinary biomarkers which can predict acute kidney injury (AKI) in critically ill patients within 12 hours [1]. A (TIMP-2) (IGFBP7) result >0.3 (ng/ml)/1,000 is associated with seven times the risk of AKI compared with a test result ≤0.3 [2]. The aim of our study was to explore the use of potentially nephrotoxic medications within the window between a positive biomarker test and the diagnosis of AKI stage 2 or 3.

Methods We identified all patients enrolled into the Sapphire study [1] who received at least one potentially nephrotoxic drug on the day of AKI (defined by stage 2 or 3 as per KDIGO classification). We subsequently...
determined the proportion of patients who had a [TIMP-2][IGFBP7] result >0.3 (ng/ml)²/1,000 before meeting the criteria for AKI.

Results Of 184 patients who developed AKI, 58% received one or more potentially nephrotoxic drug on the day of AKI. Eighty-nine percent of these patients had a positive biomarker test ≥12 hours earlier. In 41% of patients receiving one or more nephrotoxic drug on the day of AKI, at least one nephrotoxic medication was stopped within 1 day of AKI, and in 24% of patients all nephrotoxic drugs were stopped within 1 day of AKI, which implies that these medications were not absolutely necessary.

Conclusion Nephrotoxic medications are commonly used in patients who develop moderate or severe AKI. The [TIMP-2][IGFBP7] test could have identified many of these patients earlier and would have offered an opportunity to reduce exposure to non-essential nephrotoxic drugs.

P296 Retrospective analysis of the efficacy of radio-contrast-induced nephropathy prophylaxis
J Wood, N Shields, KV Wood
Maidstone & Tunbridge Wells NHS Trust, Maidstone, UK

Introduction This study investigated renal outcomes following radio-contrast (RC) administration in patients from two intensive care units (ITUs), where one gave RC-induced nephropathy (RCIN) prophylaxis, while the other did not. Acute kidney injury (AKI) during critical illness increases morbidity and mortality. ITU patients, who already suffer a variety of renal insults, often require RC, increasing their risk of developing AKI, and requiring renal replacement therapy (RRT). Evidence suggests that hydration alone is inadequate for the prevention of RCIN in ITU patients, and is contraindicated in some disease states [1]. The European Society of Intensive Care Medicine (ESICM) provides recommendations for prophylaxis [2]. The current study aimed to establish the efficacy of the ESICM recommended prophylaxis.

Methods Retrospective data from 140 Maidstone (M) ITU patients (men 101, women 39, mean age 63.5, mean APACHE 15.3) and 73 Tunbridge Wells (T) ITU patients (men 41, women 32, mean age 60.2, mean APACHE 20.2) admitted between 22 September 2011 and 22 September 2013, who underwent RC-enhanced CT, were collected. Patients on MITU received ESICM-recommended RCIN prophylaxis: 200 mg mannitol i.v. over 30 minutes prior to RC, 1.26% sodium bicarbonate 3 ml/kg/hour for 1 hour prior to RC and 1 ml/kg/hour for 6 hours post RC. TITU patients received standard critical care alone. Exclusion criteria were: those undergoing RRT prior to CT, >1 CT in 48 hours, no creatinine (Cr) data available post scan. The Cr prior to CT (baseline), at 24, 48 and 72 hours post CT scan were identified. The RFLE criteria was used to classify the changes of Cr from baseline into low risk (% change < 1.25), risk (% change < 1.5), injury (% change > 2) or failure (% change > 3, or Cr > 335 and increase of >44).

Results The total number of patients developing renal injury falling into any RFLE category for MITU at 24, 28 and 72 hours was eight (0.06%), 12 (0.09%) and 14 (0.1%), while for TITU it was five (0.07%), six (0.08%), and four (0.05%) respectively. A repeated-measures ANOVA revealed no significant differences in outcomes between the two groups overall (P = 2.35, P = 0.127) or at each time point (F = 1.93, P = 0.123).

Conclusion While RCIN is a recognised problem within the critical care population, there is little clear evidence for any prophylactic strategy to reduce this risk. This study suggests that a RCIN prophylaxis protocol based on the ESICM recommendations has no effect on the incidence of RCIN. However, further studies are needed.

P297 Base deficit and SOFA score are predictive factors of early acute kidney injury in oncologic surgical patients
A Gerente, J Almeida, E Almeida, A Louzada, C Park, J Ribeiro, J Fukushima, A Leme, E Osawa, A Rezende, J Bispo, F Galas, L Hajar
Instituto do Cancer do Estado de Sao Paulo – ICESP, Sao Paulo, Brazil

Introduction Patients who undergo major oncology surgery are under high risk to develop postoperative acute kidney injury (AKI), mainly due to inflammatory and ischemic insults. This complication results in worse outcomes. The aim of this study is to identify predictive factors of AKI in this population.

Methods We performed an observational study in 285 consecutive patients admitted to a surgical ICU after major abdominal oncology surgery. Baseline characteristics, laboratorial, clinical and intraoperative data, such as type of fluids, blood transfusion, bleeding and use of vasoressor, were collected at ICU admission. Early acute kidney injury was defined according to the Acute Kidney Injury Network classification at 48 hours of ICU admission. Logistic regression model was performed using AKI as the outcome.

Results There were 76 (26.7%) patients who developed AKI within the first 48 hours after ICU admission. In a univariate analysis, patients with AKI were more likely to be male, had higher Sequential Organ Failure Assessment (SOFA) score, higher baseline serum creatinine and urea levels, higher serum lactate levels and had more metabolic academia at admission. These patients also had a higher 24-hour Simplified Acute Physiology III score and higher length of mechanical ventilation as compared with non-AKI patients. There were no differences between patients regarding intraoperative vasoressors, type and amount of fluids, diuresis and blood transfusion. In a multivariate analysis we identified admission base deficit (BD) (OR = 1.13, 95% CI = 1.02 to 1.24, P = 0.017) and SOFA score (OR = 1.35, 95% CI = 1.2 to 1.51, P <0.001) as independent predictive factors of early AKI.

Conclusion Both SOFA score and BD may be used to predict AKI in surgical oncology patients at ICU admission. These variables allow physicians to recognize early patients who might be under risk, and anticipate measures to avoid further renal impairment.

P298 Predictors of renal recovery in critically ill patients with AKI: observations from the ongoing FBI clinical trial
S Robinson, U Larsen, A Zinck, S Zwisher, P Toft
Odense University Hospital, Odense, Denmark

Introduction The predictive value of NGAL for renal recovery is not established.

Methods Data from the first 19 patients were assessed during a multicentre low molecular weight heparin trial (FBI, EudraCT Number: 2012-004368-23). Critically ill patients with AKI are randomly assigned into either a treatment arm (1 mg/kg enoxaparin) or a control arm (40 mg enoxaparin) upon commencement of CRRT. The primary outcome is the occurrence of venous thromboembolism. NGAL was measured at baseline and during CRRT-free intervals.

Results Patients were comparable at baseline with respects to demographics, APACHE II, creatinine, NGAL, start of dialysis, and the duration of dialysis. The main cause of AKI was sepsis (42%). In 66% of the patients, the reason for starting dialysis was a combination of anuria and electrolyte disturbances. Twenty-six percent of patients were dialysis dependent after the first CRRT-free interval. Plasma NGAL levels were higher in nonrenal recovery patients (1,074 ±694 ng/ml) compared with renal recovery patients (296 ±197 ng/ml; P = 0.01).

Urine NGAL levels were higher in nonrenal recovery patients (3,885...
Comparison of two strategies for initiating renal replacement therapy in the ICU: study protocol plan for a multicenter, randomized, controlled trial from the AKIKI research group

Introduction

Patients with acute kidney injury (AKI) may require renal replacement therapy (RRT), which could result in loss of water-soluble micronutrients. Little is known about these losses in RRT and whether they differ between types of RRT. This study aims to quantify micronutrient losses during RRT in patients with AKI and to compare them in three different RRT modalities: continuous venovenous haemofiltration (CVVH), intermittent haemodialysis (IHD) and sustained low-efficiency dialfiltration (SLEDF).

Methods

A prospective observational study is being conducted at NUH. Thirty-three adult patients with AKI requiring RRT (IHD, 10 SLEDF, 10 CVVH) have been recruited. Samples of blood and RRT effluent were obtained at baseline, mid and end-session from each participant during their first RRT treatment. Samples were processed and stored at –80°C for subsequent analysis of amino acids by high-performance liquid chromatography and trace elements by inductively coupled mass spectrometry after derivatization from physiological fluids. Micronutrient losses were calculated by multiplying mass-corrected concentrations by total volume of RRT effluent, adjusted for baseline plasma concentrations and RRT dose. Data were analysed by restricted maximum likelihood estimating equations.

Results

The total baseline plasma concentration of all standard amino acids was similar between IHD versus SLEDF groups (1,812 ± 517 vs. 2,675 ± 527 μmol/l, respectively) but were higher in the CVVH group (3,194 ± 564 μmol/l). RRT reduced the plasma concentration of amino acids in the SLEDF group (to 1,732 ± 529 μmol/l; P = 0.02), but had no effect in the IHD or CVVH groups (IHD; 1,853 ± 523, CVVH; 2,845 ± 512 μmol/l). The average, unadjusted loss of amino acids was significantly influenced by mode of RRT (IHD, 5.13 ± 3.1 vs. SLEDF, 8.21 ± 4.07 vs. CVVH, 18.69 ± 3.04 g; P <0.01). The total baseline plasma concentration of trace elements was similar in the IHD, SLEDF and CVVH groups (3,797 ± 827, 3,667 ± 791, 3,642 ± 481 μg/l, respectively). By the end of the RRT session, the plasma concentration of trace elements had reduced (IHD, to 3,103 ± 827; SLEDF, to 2,805 ± 797; CVVH, to 3,433 ± 481 μg/l; P = 0.01). By the end of each RRT session, total losses of trace elements were estimated at IHD, 5.051 ± 2.312; SLEDF, 8.751 ± 2.421; CVVH, 11.258 ± 2.547 μg/l; P = 0.02 for treatment.

Conclusion

Micronutrients are lost during RRT in AKI. The degree of micronutrient loss is influenced by the type of RRT used.

Super high-flux CVHD using regional citrate anticoagulation: long-term stability of middle molecule clearance
M Siebeck1, D Kindgen-Milles2, M Worthington3, T Jones3, J Highgate4, A Lowe5, F Stedman2, N McNeillis2
1Worthing Hospital, Worthing, UK; 2Conquest Hospital, Hastings, UK; 3Guy’s and St Thomas NHS Foundation Trust, London, UK

Introduction Conventional membranes used for CRRT have a limited middle molecule clearance. New membranes called super high-flux (SHF) or high cutoff membranes have been investigated. The loss of albumin with hemofiltration is a major drawback, but these membranes can be used in CVVHD with regional citrate anticoagulation (Ci-Ca® CVVHD), which may limit albumin loss, and contribute to a prolonged filter patency and an improved and stable middle molecule clearance. We evaluated saturation coefficients (SC), plasma clearances (PCL) and serum levels of eight small and middle molecules during 72 hours of Ci-Ca® CVVHD with a SHF membrane. Methods After approval of the local committee of medical ethics and written informed consent we enrolled patients on a surgical ICU with AKI RIFLE-F who were treated with a Ci-Ca® CVVHD with a SHF membrane during 72 hours. We measured urea (0.006 kDa), creatinine (0.113 kDa), osteocalcin (5.8 kDa), B2MG (12 kDa), myoglobin (17.2 kDa), FreeLightChains (FLC) kappa (25 kDa) and lambda (50 kDa) and albumin (66 kDa) at 0 hours, 1 hour, 6 hours, 12 hours, 24 hours, 48 hours, and 72 hours. PCL, SC and serum levels during 72 hours were compared, using the Wilcoxon signed-rank test with P < 0.05. Results Four females and 10 males (mean age 68.1 ± 15.1 years; mean APACHE II score 13.7 ± 14.7; mean SAPS II score 38.7 ± 12.7) were included. The SC and the PCL (ml/minute) of small solutes like creatinine at 1 hour (1.0 ± 0.2/23.72 ± 1.04) and 72 hours (0.95 ± 0.16/22.19 ± 3.99) were not statistically significantly different (P = 0.5/P = 0.42), the PCL was slightly reduced by 6%. The creatinine serum level was reduced by 42%. The SC and PCL of B2MG from 1 hour (0.61 ± 0.09/14.9 ± 2.5) to 72 hours (0.48 ± 0.13/11.6 ± 2.96) were significantly decreased (P = 0.0024/P = 0.0061). The reduction was 23% only; the overall clearance still was high. There was almost no reduction in SC or PCL for FLC kappa from 1 hour (0.176 ± 0.047/4.14 ± 1.08) to 72 hours (0.164 ± 0.078/3.854 ± 1.87), not reaching statistical significance (P = 0.94/P = 0.81). The serum levels of B2MG and FLC kappa were decreased by 39% and 23%. The SC of albumin was low (1 hour: 0.0009 ± 0.0004) and clearance decreased rapidly within the first 6 hours from 0.021 ± 0.01 to 0.011 ± 0.009. Serum levels of albumin did not decrease (1 hour: 2.64 ± 0.51; 72 hours: 2.63 ± 0.25). Conclusion This study shows high middle molecule clearances using a SHF membrane with Ci-Ca® CVVHD for 72 hours with no loss of albumin. This set-up may improve blood purification in critically ill patients with acute kidney injury.

P302
Citrate anticoagulation for continuous venovenous haemofiltration: the impact of a novel protocol on patients receiving therapy in one regional hospital
O Tavabie1, R Pocock, M Barrett, A Retter, T Jones1, G Lad, A Munt, M Worthington1
1Worthing Hospital, Worthing, UK

Introduction Citrate has been used to anticoagulate extracorporeal haemofiltration circuits since the 1960s, and has been used as the first-line anticoagulant for continuous venovenous haemodiafiltration (CVVHDF) at Conquest Hospital since 2009. Benefits of citrate demonstrated in clinical trials include increased filter life and increased bicarbonate formation from metabolism of the citrate complex; citrate also lacks the increased bleeding risk associated with unfractionated heparin use. One of the main issues with new renal replacement therapies is the development of ideal dialysate fluids. During the initial period of citrate use at Conquest, hyponatraemia was identified as an issue, with off-license supplementation of dialysate fluid with sodium bicarbonate often necessary to prevent this. New protocols were therefore developed, designed to maximise the filtration dose and maintain normal electrolyte balance.

Methods A comparison of patients receiving CVVHDF on the 11-bed critical care unit at Conquest Hospital, Hastings was undertaken, before and after the implementation of new CVVHDF protocols. All patients receiving CVVHDF were identified from the electronic patient record system between March 2012 to 2013 and September 2013 to 2014. Patient demographics, the duration of CVVHDF and sodium bicarbonate supplementation were analysed between the groups to assess the impact of the new protocols.

Results Sixty-four patients received CVVHDF in 2012 to 2013, 61 receiving citrate and three receiving unfractionated heparin due to fulminant liver failure. Forty-seven patients received CVVHDF in 2013 to 2014, two receiving no anticoagulation due to severe coagulopathy and one receiving unfractionated heparin. The two patient cohorts assessed were similar in age (median 65.5 for March 2012 to 2013 cohort vs. 66 for September 2013 to 2014 cohort), gender mix (64% male vs. 57% male) and severity of illness as assessed by APACHE II score (23 vs. 24). Mean duration of CVVHDF was also similar (71.5 hours vs. 75 hours). A total 30/64 of 2012 to 2013 patients did not require a filter change prior to completion of RRT, compared with 23/47 of 2013 to 2014 patients. Sodium bicarbonate was added to the dialysate fluid in 29/64 2012 to 2013 patients, compared with just 2/47 2013 to 2014 patients.

Conclusion Changing protocols resulted in a significant reduction in off-license addition of sodium bicarbonate to dialysate bags without impacting on filter life, thus reducing nursing workload and removing a potential source of adverse events in this high-risk group of patients.

P303
Descriptive study of the haematological management of adult patients with severe respiratory failure receiving venovenous extracorporeal membrane oxygenation
O Tavabie1, R Pocock, M Barrett, A Retter, T Jones1, G Lad, A Munt, M Worthington1
1Worthing Hospital, Worthing, UK

Introduction Venovenous extracorporeal membrane oxygenation (VV-ECMO) is a novel therapy for severe respiratory failure (SRF). Its introduction has reduced mortality; however, patients require substantial blood product support and between 10 and 20% of cases develop a life-threatening haemorrhage.

Methods We contacted 336 practitioners at 135 centres, examining their haematological management.

Results In total 25% of practitioners contacted responded; 85% were attending physicians, predominantly based in North America and Europe, 41 and 32% respectively. Ninety-six per cent of units used a post-haemofiltration membrane oxygenator and all used a centrifugal pump. Thirty-four per cent of responders managed <10 cases a year and 60% worked in units handling <20 annually, 6% saw >50 patients. One centre did not use unfractionated heparin. Monitoring of anticoagulation varied; 52% used the aPTT, 43% the ACT and 5% the aPTTTr. Sixty per cent did not routinely measure antithrombin.

Scenario 1 was based on a patient with H1N1. Practitioners targeted a haemoglobin (Hb) of 80 to 100 g/l; however, 20% targeted a Hb outside this range; 38% favouring a transfusion threshold of <80 g/l when the patient was improving compared with 32% when the patient had just started on ECMO. Seventeen per cent of practitioners transfused platelets when the count was <30 x 10⁹/l whilst 21% maintained the platelet count >100 x 10⁹/l. Scenario 2 described a patient with SRF secondary to a hospital-acquired pneumonia. The patient developed a haemothorax, with persistent blood loss of 200 m/our. Practitioners targeted a haemoglobin concentration of 100 g/l and targeted a higher platelet count of >100 x 10⁹/l when compared with the patient in scenario 1, neither of these differences was statistically significant. Seventy-one per cent stated they would manage the patient off anticoagulation. There was no agreement as to the length of time off anticoagulation; 26% restarted anticoagulation in <12 hours, compared with 22% who advised no anticoagulation for >5 days. Scenario 3 examined the management of an incidental intracranial haemorrhage. There was a lack of consensus regarding the duration off anticoagulation; 14% of responders held anticoagulation for less than
12 hours whilst 37% held anticoagulation for >5 days and tranexamic acid was considered useful by 25%.

Conclusion There was wide variation in the use of blood products and the intensity of anticoagulation. This is not surprising given the current lack of evidence. Further work is required to provide a standardised approach.

Comparison between nafamostat mesilate and unfractionated heparin as anticoagulant during continuous renal replacement therapy

S Makino, H Kita, Y Miyatake, T Yokoyama, K Kubota, N Obata, M Egí, T Misumi, S Izuta, S Mizobuchi
Kobe University Hospital, Kobe, Japan

Introduction For continuous renal replacement therapy (CRRT), continuous administration of anticoagulant would be necessary to prevent the circuit clotting. Nafamostat mesilate (NM) is commonly used as its anticoagulant in Japan, although unfractionated heparin (UFH) is the most frequently used anticoagulant internationally. There is little study to compare the risk and benefit of NM with UFH as an anticoagulant during CRRT.

Methods We conducted a single-center retrospective observational study to compare NM with UFH as anticoagulant during CRRT. We screened subsequent critically ill patients requiring CRRT in our ICU from January 2011 to December 2013. We excluded patients who required any other extracorporeal circuit including extracorporeal membrane oxygenation, who used both NM and UFH simultaneously, or who were administered any other anticoagulant including gabexate mesilate or orukinase. The primary outcome of this analysis was filter life, and the secondary outcome was the incidence of bleeding complications during CRRT. As an initial dose, NM and UFH were given pre filter at 15 to 25 mg/hour and 1,500 to 3,000 IU/hour, respectively. The dose of both drugs was adjusted to maintain activated clotting time at post filter between 150 and 200 seconds. Filter life was assessed using the Kaplan–Meier method and the incidence of bleeding complications was compared using the chi-square test. P < 0.05 was considered to be statistically significant.

Results We included 101 patients in this study. Among them, 76 patients were with NM and 25 patients were with UFH. They used 239 filters in total; 173 with NM, 66 with UFH. There were significantly more post-surgical patients in the NM group (P = 0.001). There was no difference in age, APACHE II score, days from ICU admission to commencement of CRRT, length of ICU stay and mortality between two groups. There was no difference in median number of filters used by one patient (NM vs. heparin; median of 1.5 (IQR) vs. 2 (IQR); P = 0.27). Filter life in the UFH group was significantly longer than those in the NM group (NM vs. UFH; median of 24 hours vs. 36 hours; P = 0.01). The incidence of bleeding complications was not significantly different between two groups (P = 0.15).

Conclusion In our retrospective analysis with 101 patients, filter life with UFH was significantly longer than those with NM. The incidence of bleeding complications was not significantly differed between patients with NM and UFH.

P305

Long-term renal and survival outcomes in acute kidney injury patients receiving renal replacement therapy in intensive care

I Elsayed1, N Pavley1, J Rosser1, MJ Heap1, GH Mills1, A Tridelter1, AH Raithatha1
Sheffield Teaching Hospitals, Sheffield, UK; Whiston Hospital, St Helens & Knowsley, UK

Introduction Acute kidney injury (AKI) affects 40% of critically ill patients, with UK data reporting 5% needing renal replacement therapy (RRT). Hospital mortality is reported as being up to 60%. We sought to evaluate renal and long-term patient survival outcomes in AKI patients receiving RRT on our ICU.

Methods Data were collected from our computerised information system on all AKI patients receiving RRT on our ICU, between October 2008 and October 2013. This included demographics, APACHE II and SOFA scores, mortality and dose of RRT and ICU length of stay (LOS). Renal and patient survival at ICU discharge was collected, in addition to outcome data at 28 and 90 days and 12 months. Data were examined using Cox proportional hazard multivariate analysis, with Stata 10.1.

Results A total of 620 patients with AKI received RRT on our ICU between October 2008 and October 2013. Sixty-one per cent were male, median age was 65 years and 65 years (IQR 54 to 74). Median APACHE II score was 23 (IQR 18 to 27). Median SOFA score was 11 (IQR 8 to 13). Fifty-five per cent were mechanically ventilated. A total of 96.7% received CVVH as the principal RRT modality. Twenty-one per cent received a period of high-volume haemofiltration (HVHF) (80 ml/kg/hour), median LOS was 6 days (IQR 3 to 14). In total, 331 (53.4%) patients recovered their renal function at ICU discharge, whilst 237 (38.2%), 220 (35.4%), and 220 (35.4%) patients did not at 28 and 90 days and 12 months respectively. A total of 414 (66.7%) patients survived to ICU discharge, with 368 (59.3%), 341 (55%) and 308 (49.6%) patients being alive at 28 and 90 days and 12 months respectively. Overall patient survival at the end of follow-up was 43%. Adjusting for age and sex; APACHE II score, SOFA score and use of HVHF were associated with worse patient survival at ICU discharge (HR: 1.07, 95% CI: 1.03 to 1.11, P < 0.001; HR: 1.11, 95% CI: 1.03 to 1.19, P = 0.006 and HR: 2.27, 95% CI: 1.4 to 3.66, P = 0.001, respectively). Adjusting for age and sex; APACHE II score and use of HVHF were associated with worse renal recovery at ICU discharge (HR: 1.06, 95% CI: 1.03 to 1.09, P < 0.001 and HR: 1.55, 95% CI: 1.03 to 2.3, P = 0.032 respectively). SOFA score did not appear to significantly impact renal recovery (HR: 0.99, 95% CI: 0.94 to 1.04, P = 0.81).

Conclusion Results from our cohort suggest that, in patients with AKI presenting to ICU for RRT, long-term patient survival is significantly impaired. Renal outcomes are poor with 35% being either dialysis dependent or having severe chronic kidney disease (eGFR <15 ml/minute), at 1 year from ICU discharge. Our data do not suggest a benefit of using HVHF in AKI patients presenting to ICU for RRT.

P306

Plasma antioxidant capacity in critically traumatized patients: severity and anatomical location

G Papakitsos1, A Kapsali1, T Papakitsou2, A Roimba3
1GHA, Arta, Greece; 2GHM, Messologi, Greece; 3General Practitioner, Thessaloniki, Greece

Introduction Oxidative stress (OS) has been invoked as a relevant factor in the evolution and outcome of critical care patients. Indeed, antioxidant therapies have been used in critical care patients, but with controversial results. This may be explained by assuming OS as a homeostatically regulated parameter and both its excess and its deficit influencing severity progression. Nonetheless, antioxidant agents could mask an OS signaling role, blocking otherwise physiological responses aimed at recovery of homeostasis. We have evaluated plasma total antioxidant capacity (TAC) in traumatized patients in the emergency department (ED) and we determined its potential relationship with severity and trauma location.

Methods In a prospective observational study of ED polytraumatized patients (n = 23, mean Acute Physiology and Chronic Health Evaluation II (APACHE II) score of 11 ± 6) we measured (in the first 24 hours) plasma TAC by the ferric reducing activity/antioxidant power (FRAP). For control subjects, we used age-matched and gender-matched volunteers (n = 32). We also evaluated the contribution of antioxidant molecules (uric acid, bilirubin, and albumin) to these values.

Results Polytraumatized patients show differences in TAC with reference to control subjects. ED polytraumatized patients show high FRAP values. We found that FRAP values were inversely correlated with APACHE II score (r = –0.266, P < 0.01) suggesting that, in trauma patients, increased antioxidant response, as measured by FRAP assay, could be a pathophysiological response to stress. Albumin and uric acid concentrations reproduced the FRAP trend with severity.

Conclusion FRAP values in trauma ED patients are independently influenced by age (β = 0.271, P < 0.021), APACHE II score (β = –0.356, P < 0.001) and trauma location.
P <0.002) and head trauma (β = −0.219, P <0.045). These results accentuate the influence of trauma location and severity in TAC changes. TAC response in ED patients reinforces the need for an adequate tailoring of treatments aimed at their recovery, such as antioxidant therapies.

P307  
Hypothermia as a predictor for mortality in trauma patients
K Balvers1, JIM Brinkkade1, C Boer1, JC Goslings2, NP Juffermans2
1Academic Medical Center, Amsterdam, the Netherlands; 2VU University Medical Center, Amsterdam, the Netherlands

Introduction  
Previous studies reported hypothermia as an independent predictor for mortality. However, different cutoff points were used in these studies and external validation has never been applied. The aim of this study was to quantify the net effect of hypothermia on admission to the ICU on the 28-day mortality and to test the predictors from the developed model in another level 1 trauma center with a comparable patient population to validate the model.

Methods  
A retrospective cohort study was performed in adult trauma patients admitted to a level 1 trauma center and who were transferred to the ICU between 2007 and 2012. Different cutoff points for hypothermia were compared to find the best definition for hypothermia. Logistic regression analysis was performed to quantify the net effect of hypothermia on admission to the ICU on 28-day mortality and to develop a model with predictors. The developed model was externally validated in data from another level 1 trauma center with a comparable patient population.

Results  
In total, 722 trauma patients were included, of which 300 patients were hypothermic. The mortality in the hypothermia group was significantly higher than in normothermia patients (OR = 3.73, 95% CI = 2.02 to 7.13, P <0.001). A cutoff point of 36°C was observed as the best threshold for hypothermia (sensitivity 74%, specificity 56%). Besides hypothermia, other predictors found for 28-day mortality were APACHE II score corrected for temperature, minimum thrombocytes in first 24 hours and urea and included in the final model with an AUC of 0.89 (95% CI = 0.85 to 0.92). External validation of the model was associated with a predicted probability of an AUC of 0.64 (95% CI = 0.51 to 0.77).

Conclusion  
Hypothermia, defined as <36°C, is associated with an increased 28-day mortality. The discriminative ability of the developed model for predicting mortality in a new patient population is moderate.

P308  
Near-infrared spectroscopy to assess tissue oxygenation in patients with polytrauma: relationship with outcome
A Donati, E Damiani, R Domizi, S Pierantozzi, S Cicala, P Pelaia
Università Politecnica delle Marche, Ancona, Italy

Introduction  
We evaluated tissue oxygenation by means of near-infrared spectroscopy (NIRS) and explored its relationship with outcome in polytrauma patients.

Methods  
A prospective observational study; 37 polytrauma patients underwent NIRS monitoring (thenan eminence) every day during their stay in the ICU. A VOT was performed with a 40% tissue oxygen saturation (StO2) target. Healthy volunteers (n = 27) were studied as controls.

Results  
StO2 increased over the first 7 days only in hospital survivors (n = 29), who showed higher values as compared with healthy volunteers at days 5 and 7 (Figure 1). StO2 downslope and upslope tended to be lower in H-nonsurvivors (n = 8) (P <0.05 at days 2 and 4) as compared with H-survivors. Tissue hemoglobin index was lower in H-no survivors over the first 7 days and tended to normalize only in H-survivors (P >0.05 vs. healthy at day 7). Five patients were discharged from the ICU but did not survive until H-discharge. At discharge from the ICU, these patients were similar to H-survivors in SOFA score, heart rate, mean arterial pressure and lactate, but showed lower StO2 downslope (~13 (~16.5, −11.7)%/minute vs. −8.6 (~11.7, −6.5)%/minute, P = 0.01).

Figure 1 (abstract P308).

Conclusion  
An increase in StO2 and lower tissue oxygen extraction rates were associated with H-survival in polytrauma patients.

P309  
Features and treatment of surviving casualties in the Kunshan ‘August 2’ Explosion Accident: 40 case reports and literature review
J Liu, WU Wu
Suzhou Municipal Hospital, Nanjing Medical University, Suzhou, China

Introduction  
The aim was to analyze the injury features and treatment strategies of surviving casualties in the explosion accident on 2 August 2014 in Kunshan city (Kunshan ‘August 2’ Explosion Accident).

Methods  
We retrospectively studied 40 cases of surviving casualties in the Kunshan ‘August 2’ Explosion Accident, and systemically reviewed the relevant literature.

Results  
A total of 40 cases were admitted to our hospital within 6.3 ± 0.8 hours after the explosion accident on 2 August 2014 in Kunshan city, including 28 males and 12 females. The major injury types included burn injury, inhalation injury, blast injury (lung, eye, eardrum, and so forth), traumatic brain injury and bone fractures. All cases suffered from burn injury caused by the explosion. The mean burned area in the surviving casualties accounted for 92 ± 14% total body surface area (TBSA) and those with third-degree burns for 77 ± 19% TBSA. Additionally, incidence rate of inhalation injuries was 97.5%. There were 34 cases complicated by multiple organ dysfunction syndrome, which accounted for 85.0%. The common organ dysfunction of surviving casualties included the lungs, circulation, liver, gastrointestinal tract, kidney, brain, and coagulation. During hospitalization, the most common infectious site in surviving casualties was a burn wound, followed by blood and lung. The most common infectious strain of bacteria was Gram-negative bacteria, which accounted for 91.3%. Further analysis showed that Proteus mirabilis ranked first in occurrence, followed by Acinetobacter baumannii and Psedomonas aeruginosa, and Klebsiella pneumonia and Enterobacter cloacae ranked fourth and fifth. After intensive treatment, the mean 28-day mortality was 20.0% and 90-day mortality was 62.5%, mainly due to septic shock and multiple organ dysfunction syndrome.

Conclusion  
During the Kunshan ‘August 2’ Explosion Accident, burn injury was the leading cause of injuries. Most surviving casualties are accompanied by multiple organ dysfunction syndrome and infection.

P310  
Duration of mechanical ventilation in trauma patients: risk factor for VAP?
I Turroni, A Cecchi, A Giugni, L Copertino
Ospedale Maggiore, Bologna, Italy

Introduction  
In the literature, duration of mechanical ventilation (DMV) is often considered an important risk factor (RF) [1] for VAP [2] in critical patients; generally the whole duration of MV is taken into
account, including days before and after infection onset. We tried to assess whether, counting only MV days prior to VAP development (MVp), something would change.

Methods We considered, in a 10-year period, data prospectively collected in our database (4D solution, V111) on trauma patients admitted to the ICU directly from the emergency department. Inclusion criteria were: age ≥16 years, ICU length of stay (ICUlos) ≥4 days, DMV ≥48 hours; we excluded patients who received antibiotics before VAP (or during the whole stay, for patients without VAP) and with incomplete data. Data were: age, sex, prehospital GCS <9, prehospital intoxication (preHTI), admission base excess (BE), Injury Severity Score (ISS), surgery, massive transfusion, feeding, antacids, nursing, DMV, ICUlos and MVp. MVp was calculated as the difference between the first day of VAP and the first day of MV in patients who developed VAP (vapY) and whole DMV in patients that did not (vapN). We only considered the first infectious episode. The outcome was VAP onset. Group comparison was made with Fisher’s exact test and Student’s t test. Significant variables were evaluated in a logistic regression (LR) model; the Hosmer–Lemeshow test (HL) was used as the post-estimation test. Odds ratio (OR) and 95% confidence interval (95% CI) were calculated. Statistical significance for P <0.05. We used Stata/IC 10.1 for analysis.

Results A total of 541 patients met the inclusion criteria, 378 (69.9%) developed VAP. MVp does not seem to be a RF for VAP because they are longer in vapN than in vapY (mean MVp 5.5 vs. 4.41, P = 0.001). PreHTI (vapY/N: 49.74%/38.65%; OR: 1.57; 95% CI: 1.08 to 2.28), ISS (mean vapY/N: 28.4/25.55; P = 0.0018), BE (mean vapY/N: –3.76/–3.04; P = 0.03) were significantly different between the two groups. In LR only preHTI (OR: 1.47; 95% CI: 1.01 to 2.15) and ISS (OR: 1.03; 95% CI: 1.01 to 1.05) are RF for VAP (HL: P = 0.133).

Conclusion In our study MVp are not a RF for VAP in trauma patients, although the whole DMV is longer in patients with VAP (mean DMV vapY/N: 13.57/6.09; P = 0.0001). Further studies could confirm whether the whole DMV in trauma patients with VAP is a consequence of infection.

Missed fractures in severely injured patients
H Park
Dankook University Hospital, Cheonan City, South Korea

Introduction The purpose of this study is to analyze anatomic distributions, diagnostic methods, and prognosis of missed fractures in patients with severe injury.

Methods A review of single-institutional medical records between January 2001 and May 2012 identified 58 patients with 62 delayed diagnoses of fractures among 4,643 severely injured patients older than 20 years with Injury Severity Scores higher than 16. We evaluated combined injuries, location of fractures, diagnostic methods, and reasons for missed diagnosis at initial examination.

Results Among 62 missed fractures, there were eight cases of spine fracture, 10 cases of peri-shoulder joint fracture, eight cases of upper extremity fracture, 10 cases of pelvis of acetabulum fracture, and 26 cases of lower extremity fracture. Head injury was the most common concomitant injury (23 cases). Initially missed fractures were most commonly discovered by official reading by radiologists. The most common reasons for misdiagnosis were the use of improper radiologic study and missed-reading of proper radiologic studies.

Conclusion In order to prevent misdiagnosis of fractures in patients with severe injury, meticulous physical examination with suspicion of fractures should come first. In addition, obtaining proper radiologic study and thorough evaluation of radiologic images are important to decreasing the rates of missed fracture diagnoses. In addition, thorough surveillance for ipsilateral fractures is important in extremities with identified fractures.

In-depth study of road accidents in Florence: understanding the biomechanical effects in major trauma involving vulnerable road users
A Franci1, S Piantini2, M Pierini2, A Peris1, M Mangini1
1A.O.U. Careggi, Firenze, Italy; 2University of Florence, Italy

Introduction Road accidents are the leading cause of death for young people, 50% being represented by vulnerable road users (VRU) (pedestrians, cyclists). In-depth accident studies assess the consequences of lack of use of safety devices and the need to develop specific impact objects.

Methods We have performed in-depth studies on road trauma admitted to our ICU [1]. Medical and engineering data were cross-matched during the correlation process. Injuries suffered by each person were related to combined injuries, location of fractures, diagnostic methods, and prognosis of missed fractures in patients with severe injury.

Results The team studied 52 VRU crashes that occurred in an urban area. The clinical data included an injury assessment using total body CT scan, Injury Severity Score (ISS), Abbreviated Injury Score (AIS), ICU and hospital length of stay and outcome score. Engineers collect data onsite with the partnership of the police, and assess the dynamics of the vehicles with the most advanced reconstruction techniques. Injuries suff ered by each person were related to combined injuries, location of fractures, diagnostic methods, and prognosis of missed fractures in patients with severe injury.

Conclusion Injuries suff ered by each person were related to combined injuries, location of fractures, diagnostic methods, and prognosis of missed fractures in patients with severe injury.
Endogenous microparticles drive the proinflammatory host immune response in severely injured trauma patients

N Curry1, K Balvers2, DJ Kleinveld2, AN Boing2, R Nieuwland2, JC Goslings1, NP Juffermans2
1John Radcliffe Hospital, Oxford, UK; 2Academic Medical Center, Amsterdam, the Netherlands

Introduction Severe trauma affects the immune system, which in turn is associated with poor outcome. The mediators driving the immune responses in trauma are largely unknown. The aim of this study was to investigate the role of endogenous microparticles (MPs) in mediating the immune response following severe trauma.

Methods A prospective, observational substudy of the Acute Coagulopathy and Inflammation in Trauma (ACIT) II study was performed at our academic level 1 trauma center. Adult multiple trauma patients with an Injury Severity Score of 15 or higher were included between May 2012 and June 2013. Ex vivo whole blood stimulation with lipopolysaccharide was performed on aseptically collected patient plasma containing MPs and in plasma depleted of MPs. Flow cytometry and transmission electronic microscopy were performed on plasma samples to investigate the numbers and cellular origin of MPs. Healthy individuals served as a control group.

Results Ten trauma patients and 10 healthy individuals were included. Trauma patients were significantly injured with a median ISS of 19 (17 to 45). On admission to the hospital, the host response to bacterial stimulation was blunted in trauma patients compared with healthy individuals, as reflected by decreased production of IL-6, IL-10 and TNFα (P < 0.001). In trauma patients, MP-positive plasma was associated with a significantly higher synthesis of IL-6 and TNFα compared with plasma depleted of MPs (P = 0.047 and 0.002 respectively). Compared with healthy individuals the number of circulating MPs was significantly decreased in trauma patients (P = 0.009). Most MPs originated from platelets. Multiple cellular protrusions, which result in MP formation, were observed in plasma from trauma patients, but not in healthy controls.

Conclusion On admission, trauma patients have a reduced immune response towards endotoxin challenge which is, at least in part, mediated by MPs, which circulate in low numbers and in early stages. Most MPs originate from platelets, which indicates that these cells may be the most important source of MPs involved in initiating an inflammatory host response post injury.

DNA and sRAGE circulation in the early phase after polytrauma

P Joly1, C Massé2, D Dwivedi2, P Liaw2, J Marshall3, Y Berthiaume2, E Charbonney4
1University of Montreal, QC, Canada; 2McMaster University, Hamilton, ON, Canada; 3University of Toronto, ON, Canada; 4CRHSCM-University of Montreal, QC, Canada

Introduction Various DAMPS, alarmins are released after trauma. The soluble receptor for advanced glycation endproducts (sRAGE) was reported to be associated with acute renal failure and duration of ventilation[1]. Cell-free DNA (cfDNA) has been associated with prognosis in trauma patients [2]. We studied the kinetics of these two biomarkers over the first 5 days, in a cohort of severely ill trauma patients.

Methods Patients who had sustained serious traumatic injury, within 24 hours of trauma, were recruited in a level I trauma center. We collected ISS, baseline demographic characteristics, resuscitation information and daily organ dysfunction (MOD) scores, over 10 days. Blood samples were collected within 24 hours of trauma (day 0) and on days 1, 3 and 5. sRAGE was measured by ELISA and cfDNA was measured by UV absorbance after plasma isolation.

Results Median ISS was 39 and mortality was 21% (8/38). During the first 5 days after trauma, the median concentration of sRAGE (Figure 1) decreased significantly over time (P < 0.0001) while median levels of DNA did not (P = 0.73), and remained elevated compared with normal control. No correlation was found with ISS. Patients initially in shock had lower levels of sRAGE or cfDNA (P < 0.05) and had received more fluid (10.6 l vs. 5.25 l) or blood (6 l vs. 0.5 l). Day 3 and day 5 sRAGE levels were inversely correlated with PRBC received. Medians of sRAGE on days 0 (1,301 vs. 730 pg/ml) and day 1 (925 vs. 760 pg/ml) were significantly higher in nonsurvivors (P < 0.01). Finally, day 0 sRAGE was correlated with the maximal (r = 0.44; P = 0.007) and the cumulative renal failure component of the MODS, over the 10 days (r = 0.48; P = 0.005).

Conclusion DNA and sRAGE kinetics differ following trauma. Early elevation of sRAGE predicts mortality in univariate analysis and correlates with subsequent renal failure.

Clinical decision rule for cervical magnetic resonance imaging in suspected cervical spinal cord injury without bony injury is useful in predicting severity of cervical stenosis

T Inagaki1, A Kimura1, A Hagiwara1, R Sasaki1, K Kobayashi1, A Inaka1, G Makishi2
1National Center for Global Health and Medicine Hospital, Tokyo, Japan; 2Seirei Hamamatsu General Hospital, Shizuoka, Japan

Introduction Cervical spinal cord injury (CCI) without bony injury (CCIWOBI) is more frequent among Asian than among Caucasian populations and shows various extents of severity. Cervical magnetic resonance imaging (MRI) is useful for detecting intramedullary lesions, ligament injuries and intervertebral disk hernias, but some patients with mild CCIWOBI do not show clinically significant abnormalities on MRI. To date, the cost–benefit ratio of performing MRI in addition to computed tomography (CT) is unclear. We have developed a clinical decision rule for cervical MRI (MR-CDR), indicating MRI for patients >70 years old with ossification of the posterior longitudinal ligament on CT or injury in a ground-level fall or a fall down stairs. The objective of the present study was to prospectively validate this MR-CDR for cervical MRI in patients with suspected mild CCIWOBI.

Methods We have been conducting a prospective observational study in two institutions in Japan since September 2012, enrolling patients with CCIWOBI among head or neck trauma patients >16 years old brought in by ambulance. We collect data about patient characteristics, injury profiles, neurological findings, results of radiological examinations, and medical courses. We then analyze the sensitivity and specificity of MR-CDR for detecting intramedullary lesions on MRI and conduct further analysis.

DNA and sRAGE kinetics (days).

Figure 1 (abstract P314).
Results During the study period, 63 patients were brought in with CCIWOBI. Mean age was 60.6 years (standard deviation, 17.9 years) and 76% were male. Forty-five patients presented with mild symptoms (Frankel Grade D). Cervical MRI was performed for 23 patients. Sensitivity and specificity of MR-CDR in detecting intramedullary lesions on T2-weighted imaging among cases of suspected mild CCIWOBI were 85.7% (95% confidence interval (CI), 60.1 to 96.0%) and 33.3% (95% CI, 12.1 to 35.4%). Further analysis showed a significant difference in minimal spinal canal diameter as measured on sagittal T2-weighted imaging between the MR-CDR-positive and MR-CDR-negative groups (5.0 mm vs. 8.3 mm, \(P = 0.0003\)). One patient underwent surgery during hospitalization and no patients experienced exacerbated neurological findings. No significant differences were evident between groups in discharge status, duration of hospitalization, or neurological findings at discharge.

Conclusion MR-CDR was not validated for predicting the existence of intramedullary lesions on cervical MRI. MR-CDR is useful in predicting the severity of cervical stenosis.

Accuracy of targeted wire-guided tube thoracostomy in comparison with classical surgical chest tube placement: a clinical study
A Protic, I Barkovic, A Sustric
University Hospital Rijeka, Croatia

Introduction Chest tube malfunction, after the tube thoracostomy, is often the result of an inappropriate chest tube tip position. The aim of this study was to analyze the precision of chest tube placement using the targeted wire guide technique (TWG technique) with a curve dilator and to compare it with the classical surgical technique (CS technique).

Methods In this clinical study 80 patients with an indication for thoracic drainage due to pneumothorax or pleural effusion were included. The experimental group contained 39 patients whose chest tube was placed using the TWG technique. The control group contained 41 patients whose chest tube was placed using the CS technique.

Results The comparison of the outcomes of the two techniques applied suggests that the TWG technique was significantly more successful, irrespective of patient diagnosis (TWG vs. CS in all patients, 78.4% vs. 36.6%, \(P < 0.001\)). See Table 1.

Table 1 (abstract P316)

Evaluating trauma care: comparison of early versus late tracheostomy ICU data outcome on injured patients
V Kaldis¹, N Mourelatos¹, D Markopoulou1, K Venetsanou¹, E Diogou¹, E Papadaki¹, D Chroni¹, I Alamanos¹
¹General Hospital KAT-EKA, Kifisia Athens, Greece; ²ICU Research Unit KAT, Kifisia Athens, Greece

Introduction In the surgical ICU, bedside tracheostomy (T) is one of the most frequently applied surgical techniques for multi-injured patients mainly with TBI [1]. The optimum surgical time decision for T still remains a contradiction in trauma. This retrospective study was designed to register all trauma patients who underwent T, during 60 months of observation (2009 to 2013), in order to identify factors associated with their ICU outcome on the basis of the T day (A <10th day >B) after tracheal intubation.

Methods Seventy-eight injured patients in the ICU underwent T, from a total of 403 issues; 58 male and 20 female, with mean age 59.3 and 74.7 years respectively. The total length of ICU stay recorded was 2,096 days, nursing time 26.55 (4/93), whereas the T time was adjusted between the 6th and 16th day (mean 11th). Mean ISS score was 22.59 (9 to 50). Classification according to trauma type was TBI (n = 44) followed by thoracic trauma. Thirty-one male survivors were discharged from the ICU, to the ward. The mortality rate amounts to 47 cases due to infectious/non-infectious nosocomial complications and multiorgan dysfunction syndrome. Clinical ISS, the type of injury, ICU length of stay (LOS), T day, demographic (gender, age) data and ICU outcome were recorded. Statistical analysis was performed with GraphPad S.O.

Results There is positive significant correlation between T day and LOS of injured patients (\(P <0.001\), Spearman coefficient = 0.1672). Statistical analysis by Mann−Whitney test, between groups A and B, showed significant differences in ICU LOS (\(P <0.001\); no significant differences (\(P <0.05\) were found for age, ISS and outcome (Table 1).

Conclusion The optimum and early time point of tracheostomy seems to be directly related with LOS in the ICU, independently of the rate of ISS, patient’s age and outcome. These results could account for ICU cost-effectiveness, as diminished LOS decreased the overall cost.

Factors related to sepsis and outcome in multiple trauma patients
H Pavlou, E Pappa, M Efthakopoulou
KAT-EKA General Hospital, Kifisia, Athens, Greece

Introduction The outcome of multiple trauma patients is related to a number of diagnostic and therapeutic interventions during hospitalization. ICU patients with severe trauma are susceptible to sepsis leading to poor outcome. Factors associated with the occurrence of sepsis and the outcome of these patients were investigated.

Methods We studied retrospectively all trauma patients admitted to the ICU of KAT General Hospital in Athens during the last 3 years and were treated for more than 5 days. Age, gender, the type of injury, the severity of injury (Injury Severity Score), the length of ICU stay, severe sepsis, coexisting diseases, the outcome and the cause of death were recorded. Logistic regression and chi-square tests were used for statistical analysis.

</tbody>
</table>
Results A total of 106 multiple trauma patients, 85 men and 21 women, met the inclusion criteria. Depending on their age, patients were divided into two groups: <60 years old and >60 years old. In both groups, gender, the type and severity of injuries and the length of ICU stay were not associated with outcome. The length of ICU stay was correlated with severe sepsis and coexisting diseases (P < 0.01) in both groups. Mortality was not different in the two groups. The presence of at least one coexisting disease was significantly associated with mortality (P < 0.007). Sepsis was significant cause of death in trauma patients >60 years (P < 0.05).

Conclusion In multiple trauma patients, the length of ICU stay and comorbidities influence the occurrence of severe sepsis, comorbidities increase mortality, and sepsis is the leading cause of death in trauma patients >60 years old.

Ventilator-associated pneumonia in a trauma ICU
M Raja, A Ely, P Zolfaghari
Royal London Hospital, London, UK

Introduction Ventilator-associated pneumonia (VAP) is associated with increased length of ventilation, ICU stay, mortality, cost and antibiotic burden [1]. There is a large variation in reported rates of VAP partly as a result of inconsistencies in definition [2]. We explored a more pragmatic definition to describe the VAP rate, antibiotic burden and outcome of VAP in a 44-bed adult critical care unit in a level 1 trauma centre.

Methods A retrospective review of all adult patients admitted to the ICU at The Royal London Hospital over a 6-month period (February to August 2014). The diagnosis of VAP was based on the Clinical Pulmonary Infection Score. Patients were identified with VAP if they were started on antibiotics for chest sepsis 48 hours after start of mechanical ventilation. Demographic, clinical, microbiological and radiological data were collected to identify risk factors, and compare VAP and non-VAP groups. Chi-squared and ANOVA tests were performed using the SOFA statistics package.

Results A total of 535 mechanically ventilated patients were admitted in the study period, with 281 ventilated for more than 48 hours. The incidence of VAP was 11% in all ventilated patients and 19.6% in those ventilated more than 48 hours. VAP rates were 31% in polytrauma, 25% in neurotrauma and 18% in the neuromedical/surgical cohort. Early and late onset VAP were equal in number. Patients with VAP spent longer on mechanical ventilation (9 ± 9 in no VAP vs. 18 ± 18 days in VAP patients; P < 0.001), and had longer ICU and hospital LOS (11 ± 10 vs. 22 ± 20 days; P < 0.001). However, APACHE II scores and hospital mortality were unaffected (VAP 33.3% vs. no VAP 37.6%; P = 0.173). Despite rising inflammatory markers and secretion load, many patients did not exhibit oxygenation deficits. Sputum microbiology showed S. aureus, H. Influenza, Klebsiella and Enterobacter as predominant pathogens with low rates of Pseudomonas, Acinetobacter and other resistant organisms. Average length of antibiotic use was 6 (3 to 18) days.

Conclusion Chest sepsis after 48 hours of mechanical ventilation commonly complicates neurocritical illness and polytrauma requiring significant ICU resources and antibiotic burden. However, it does not affect mortality. Further research should focus on pathophysiology and new preventative measures to reduce VAP in the at-risk population.

Normobaric oxygen paradox and erythropoietin production in critically ill patients: a prospective observational study
S Zuccari, A Donati, E Damiani, R Castagnani, N Mininno, P Pelaia
Università Politecnica delle Marche, Ancona, Italy

Introduction The normobaric oxygen paradox (NOP) postulates that a period of normobaric hypoxemia followed by a rapid return to normoxia will create a condition of relative hypoxia, which acts in turn as a stimulus for erythropoietin (EPO) production [1]. Variations in GSH and oxygen free radical (ROS) levels may be involved in this process. We tested the NOP in critically ill patients.

Methods A prospective observational study on 38 mechanically ventilated (FiO2 <50%) patients with no active bleeding, no blood transfusion needed, and no kidney failure. Eighteen patients underwent a 2-hour period of normobaric hypoxia (FiO2 = 100%), 20 patients were evaluated as controls (no FiO2 variations). EPO was assayed at baseline (t0), 24 hours (D1) and 48 hours (D2). Serum GSH and ROS were assayed at t0 (baseline), t1 (2-hour FiO2, 100%) and t2 (2-hour return to normoxia) in 12 patients in the hyperoxia group.

Results EPO tended to increase in the hyperoxia group over time (P = 0.05), while it remained stable in the control group (P = 0.53) (Figure 1). ROS levels increased at t1 and decreased at t2. GSH tended to decrease at t1 and increased at t2 in the hyperoxia group.

Conclusion Relative hypoxia after a transient period of normobaric hypoxemia induces an increase in GSH levels, thus enhancing ROS scavenging. This may act as a stimulus for EPO production.

Figure 1 (abstract P320).
0.5 mg/l. The correlation between PATHFAST and STRATUS results was particularly close in the patient group with VTE (r = 0.9694), whereas slightly lower results were obtained with STRATUS in the control group. With the widely used cutoff value 0.5 mg/l, PATHFAST demonstrated suitable sensitivity but not STRATUS. ROC analysis indicated that optimal cutoff values could be set at either 0.5 or 0.6 mg/l and at 0.3 or 0.4 mg/l for PATHFAST and STRATUS, respectively.

**Conclusion** By use of the PATHFAST D-dimer assay only six of diagnoses were missed at the time of first presentation compared with 10 diagnoses missed by the VIDAS D-dimer Exclusion assay, yielding higher sensitivity of the PATHFAST D-dimer assay compared with the VIDAS assay (90% vs. 83%). The STRATUS assays showed comparable performance and appeared to be suitable for the exclusion of VTE in the emergency room setting, whereas PATHFAST demonstrated superior sensitivity. Moreover, the PATHFAST analyzer allows simultaneous determination of D-dimer and cardiac troponin I within 16 minutes from whole blood samples. Therefore, this method might be useful at the point of care for early diagnostic assessment of patients with symptoms of PE or chest pain admitted to the ER or to the chest pain unit.

Using rivaroxaban in patients with venous thromboembolism

T1ynygin, O Darabrin, B Todurov, S Shcherbakov, D Gavrychenko, G Mazurenko

Odessa National Medical University, Odessa, Ukraine

**Introduction** A prospective study was conducted in patients for treatment of venous thromboembolism (VTE) to compare the effect of enoxaparin and rivaroxaban using the method of low-frequency piezoelectric thromboelastography (LPTEG) for checking coagulation activation markers.

**Methods** A total of 60 patients entered the Odessa Clinical Regional Hospital for treatment venous thromboembolism. Patients were divided into two groups. The first group (n = 30) were receiving enoxaparin in dosage 1.5 mg/kg subcutaneously per day. The second group (n = 30) were receiving rivaroxaban orally 15 mg/day. For checking the coagulation state we were using such indicators of LPTEG as constant thrombin activity (CTA), intensity of coagulation drive (ICD) and gel point (GP). We performed LPTEG three times per day: 4, 12 and 24 hours after taking the drug to check for changes in the coagulation state in both groups of patients.

**Results** The peak action of enoxaparin and rivaroxaban was observed at 4 hours post administration. LPTEG indicators that determine the coagulation state after 4 hours in the first group: CTA was decreased by 72.12% (P < 0.05), ICD was decreased by 68.44% (P < 0.05), GP was increased by 17.9%; in the second group: CTA was decreased by 76.24% (P < 0.05), ICD was decreased by 74.52% (P < 0.05), GP was increased by 23.34%. After 12 hours, CTA in the first group decreased by 22.41%, ICD decreased by 5.3%, GP increased by 8.12%, indicating reduction of hypocoagulation effect; in the second group, CTA decreased by 39.35% (P < 0.05), ICD decreased by 40.24% (P < 0.05), GP increased by 18.25%. After 24 hours in the first group LPTEG indicators returned to the original value, and in the second group of patients CTA was decreased by 15.14%, ICD was decreased by 6.62%, GP increased by 14.22%.

**Conclusion** Using LPTEG showed the hypocoagulation effect of continuous rivaroxaban 24 hours after oral administration compared with enoxaparin, which retains less hypocoagulation effect 12 hours after administration. LPTEG indicators in the second group were bigger than in the first group after 12 hours: CTA 43.07%, ICD 69.72%, GP 54.12%.

**P323**

Is delaying pharmacological thromboprophylaxis associated with thromboembolic complications?

P Padim1, A Alshafai1, S Canestrini1, S Rizoli2, S Rizoli2, J De Rezende Neto2, G Mazurenko1

1Universidade de Sao Paulo, Ribeirao Preto, Brazil; 2St Michael’s Hospital, Toronto, ON, Canada; 3St George’s Hospital, London, UK

**Introduction** Thromboembolic complications (TEC) are very common and lethal in patients suffering from traumatic injury [1]. The trauma clinical guidelines recommend the administration of pharmacological thromboprophylaxis (PTP) to reduce the risk of developing TEC [2]. However, it is unknown whether delayed PTP initiation increases risk of TEC. We hypothesize that delayed PTP initiation is associated with increased TEC rates.

**Methods** A retrospective chart review (2010 to 2013) was conducted on adult trauma patients that were admitted into a level 1 trauma centre in Toronto. Demographics, date of PTP initiation, date of TEC diagnosis (CT-PE/US Doppler), injury type and severity were collected. A comparison between early and late PTP initiation has been made with regards to TEC development. Student’s t test, univariate and multivariate logistic regression analyses were performed.

**Results** A total of 1,312 patients received PTP, 821 (62.5%) initiated early PTP (within 48 hours) while 491 (37.5%) initiated after 48 hours. The group that initiated early prophylaxis was younger (mean: 46 vs. 55, P < 0.0005), had lower ISS (mean: 17 vs. 24, P < 0.0005), shorter length of stay (LOS) (mean: 11 vs. 23, P < 0.0005), more pelvic fractures (19% vs. 13%, P = 0.0058), more head injury (AIS Head ≥ 3, P < 0.0005), less blunt trauma (85% vs. 95%, P < 0.0005), lower incidence of TEC (5.3% (44) vs. 8.5% (42), P = 0.023), and lower mortality rate (1.5% vs. 7.5%). Univariate analysis showed LOS (P < 0.0005), ISS (P < 0.0005), time to PTP initiation (P = 0.0018) and blunt MOI (P = 0.0099) significantly associated with TEC events. Multivariate analysis, however, showed PTP events correlated only to LOS (P = 0.0001). Stepwise multiple logistic regression confirmed LOS as independently associated with TEC events (95% CI = 0.003, 0.006, P < 0.0005).

**Conclusion** Mortality rates in patients with delayed PTP are higher. Our study shows LOS as the only independent predictor for TEC. However, this might not necessarily reflect causation. Delayed PTP appears not to be an independent predictor to TEC events in trauma patients, which favours current clinical trends when it comes to contraindicating early PTP initiation.

Impact of introducing guidelines for thrombolysis of submassive pulmonary embolism at a large UK teaching hospital

GP Misselbrook

University Hospitals Southampton NHS Foundation Trust, Southampton, UK

**Introduction** Pulmonary embolism (PE) is a significant cause of death with 10% of patients dying within 3 months [1]. Multiple studies now advocate the use of thrombolysis (TPA) in both massive and submassive PE [1,2]. This audit assessed the impact of introducing a guideline allowing for thrombolysis of submassive and massive PE at a large UK teaching hospital.

**Methods** Retrospective data collection using notes and imaging to risk-stratify patients. First audit ran from January to June 2012. New guidance was introduced in March 2013 (Figure 1) after which a second cycle ran for a further 6 months.

**Results** Re-audit revealed 46 patients with radiological evidence of massive or submassive PE on CTPA (32% of all PEs). Ten patients had clinical features of submassive PE and nine presented as massive PE. Previous guidelines suggested consideration of TPA in only seven patients in 6 months. TPA was given to two patients; however, six patients had no contraindications to treatment (Table 1). Limitations to TPA administration were late recognition of submassive PE and inadequate knowledge of changes to guidelines.

**Conclusion** Delivering a service that offers TPA to patients with submassive PE significantly increases the need to consider this therapy. Introducing this service is only effective if doctors initially assessing these patients are aware of recent changes to guidelines for PE.

Introduction

Asymptomatic deep vein thrombosis (DVT) including catheter-related thrombosis (CRT) is an increasingly recognized disease entity in critically ill patients. However, the reported rate and outcome of DVT vary widely depending on study design, patient background and detecting method. The objective of this study is to evaluate the incidence and outcome of DVT in adult critically ill patients.

Methods

This study is a prospective cohort study of patients admitted to a medical and surgical ICU from 1 July 2014 to 15 October 2014. All consecutive patients over 18 years of age and with expected ICU stay over 72 hours were included. Patients who had previous history of DVTs were excluded. We examined internal jugular vein, subclavian vein, axillary vein, brachial vein, femoral vein, superficial femoral vein, and popliteal vein on ICU admission and within 48 hours after ICU discharge. The DVT was diagnosed using compression ultrasonography with color Doppler. Images were interpreted by two independent investigators trained in ultrasonography. All patients received intermittent pneumatic compression and unfractionated heparin twice daily during their ICU stay. Once the DVT was detected, therapeutic anticoagulation was initiated. Contrast-enhanced CT was performed when the patients were suspected to have pulmonary embolism. The primary outcome was the incidence of DVT during the ICU stay. Patients were followed until their hospital discharge.

Results

A total of 51 patients were included. The median age and BMI were 73 years and 23 kg/m², respectively, 31% were female and 69% were surgical critical care patients. The median APACHE II and SOFA scores were 20 and 8, respectively. Risk factors associated with DVT were presence of central venous catheter 63%, malignancy 9% and hemodialysis 14%. The rate of DVT was 18.6% and the rate of CRT was 13.7%. All of these were asymptomatic and seen in neck and upper extremities. There was no DVT-associated adverse event (pulmonary embolism, bleeding) during hospital stay. The 28-day all-cause mortality rate was 3.4%.

Conclusion

While incidence of asymptomatic DVT is relatively high in adult critically ill patients, they were found only in the neck and upper extremities without any adverse event. Further research is needed to evaluate the clinical significance of this type of DVT.

Examining venous thromboembolic disease in postoperative neurosurgical and trauma patients in the ICU

D Markopoulou, K Venetsanou, K Venetsanou, E Papadaki, E Papadaki, V Kaldis, V Kaldis, M Mourelatos, M Mourelatos, I Alamanos, I Alamanos

KAT Hospital Athens, Kifisia, Greece

Introduction

Despite preventive anticoagulation therapy measures, venous thromboembolic disease is a major cause of morbidity and mortality among patients hospitalized in ICUs. In fact, pulmonary embolism is not only the most serious manifestation of the disease, but also one of the primary causes of sudden death. The aim of this study is to investigate the frequency of thromboembolism and pulmonary embolism in ICU hospitalized trauma and neurosurgical patients.

Methods

One hundred ICU patients, 51 postoperative neurosurgical and 49 trauma, were included in the study. Patients' demographic data as well as medical history, temperature, white blood cells and platelets counts were recorded on admission, the day of thrombosis diagnosis and the final outcome of their treatment. Statistics were performed with SPSS-19. P <0.05 was considered significant.

Results

Thirty-eight out of 100 patients presented thrombosis, 14 trauma and 24 neurosurgical. We examined the correlation of thrombosis development during hospitalization with diagnosis, treatment allocated time and overall patient outcome. It was found that neurosurgical patients developed thrombosis more frequently than trauma patients (P <0.05). In relation to diagnosis, thrombosis was prevalent among patients with brain lesions (P = 0.018). Regarding the type of thrombosis, pulmonary embolism was also commonly apparent among individuals with brain lesion (P = 0.020). In addition, there was a statistically significant correlation in thrombosis occurrence between hospitalization day (P <0.01) and patients’ outcome on discharge (P <0.001). The type of thrombosis was directly associated with poor outcome, especially one that resulted from central catheters (P <0.001) and pulmonary embolism (P <0.001). However, no correlations were found with temperature, white blood cells and platelet counts on admission (P > 0.05).

Conclusion

Thrombosis affects the ICU patient’s final outcome. The type of thrombosis contributes to a poor outcome and mainly the occurrence of pulmonary embolism significantly increases the mortality rate.

Introduction

Computed tomographic pulmonary angiographic findings to predict adverse outcomes in acute pulmonary embolism

P Tajarernmuang, I Euathrongchit, C Liwsrisakun, A Deesomchok, T Theerakittikul, C Burmoongkht, P Pothirat, A Limsukon

Chiang Mai University, Chiang Mai, Thailand

Introduction

Computed tomographic pulmonary angiography (CTPA) has been used as a standard tool for diagnosing an acute pulmonary embolism (APE). The right ventricular (RV) strain signs may be used to predict adverse outcomes. However, the results are still controversial. The primary objective of our study was to evaluate the relationship between the RV strain signs and respiratory failure requiring mechanical ventilation or death in APE. The secondary objective was to identify clinical factors which related to those outcomes.
Methods CTPA and the medical records of patients with suspected APE on admission from June 2011 to March 2013 were reviewed. RV dysfunction signs included right ventricular to left ventricular (RV/LV) diameter ratio, interventricular septal shift, main pulmonary artery to ascending aorta (mPA/AA) diameter ratio, IVC contrast reflux, SVC diameter, IVC diameter, PA diameter and azygos vein diameter. Clinical factors included cardiovascular, respiratory parameter and also time to diagnosis and treatment.

Results There were total of 36 cases with suspected APE on admission. Ten patients required mechanical ventilation (27.8%) and seven patients died (19.4%). Interventricular septal (IVS) shift was a significant risk factor of in-hospital death (85.7% vs. 27.6%, \( P = 0.008 \)) and respiratory failure (70% vs. 26.9%, \( P = 0.026 \)). The sensitivity, specificity, positive predictive and negative predictive values of IVS shift to predict in-hospital death were 85.7%, 70%, 42.8% and 95.5%, respectively. The sensitivity, specificity, positive predictive and negative predictive values of IVS shift to predict respiratory failure were 70%, 73.1%, 50% and 86.4%, respectively. The ratios of RV to LV diameter and the ratio of main pulmonary artery to ascending aorta diameter tended to be higher in the nonsurvivor group. The clinical factor that predicted mortality was the PaO2 to FiO2 ratio (P/F ratio). Mean P/F ratio in survivor and nonsurvivor groups was 246.1 ± 94.1 vs. 132.2 ± 78.1, respectively (P = 0.011). P/F ratio ≤150 was the best predictor of mortality (66.7% vs. 8.7%, \( P = 0.008 \)).

Conclusion The IVS shifting from CTPA and P/F ratio ≤150 helps predict poor outcomes in APE.

Mean platelet volume and mean platelet volume/platelet count ratio in risk stratification of pulmonary embolism
Y Vande Walle1, S Johnson2, E Harvey3, J Kincaid3
1University Hospital Ghent, Belgium; 2Medicus Economics, LLC, Boston, MA, USA; 3Aexion Pharmaceuticals, Cheshire, CT, USA

Introduction Recently, mean platelet volume (MPV) was reported to predict early death in acute pulmonary embolism (PE). The aim of this study was to investigate the role of MPV and MPV/platelet count ratio (MPV/P) in risk stratification of patients with acute PE.

Methods We retrospectively reviewed the medical records of patients with acute PE admitted to the emergency department. In addition to the clinical evaluation, platelet count and MPV were measured on admission.

Results One hundred and fifty-two patients were included. Patients with right ventricular (RV) dysfunction had significantly higher MPV levels and MPV/P than patients without RV dysfunction. Receiver operating characteristic analysis revealed that a MPV cutoff of 7.85 fl provided 53.3% sensitivity and 68.5% specificity, and a MPV/P cutoff of 0.0339 fl/(109/l) provided 69.6% sensitivity and 65% specificity for prediction of RV dysfunction. There was a positive correlation between MPV/P and RV diameter. The low-risk PE group had lower MPV and MPV/P than the massive PE and submassive PE groups.

Conclusion Mean platelet volume and mean platelet volume/platelet count ratio are associated with RV dysfunction and clinical severity in acute PE. Low MPV and MPV/P levels may be an indicator of low risk in patients with acute PE.

P329
Progression to end-stage renal disease is reduced with eculizumab in patients with atypical haemolytic uraemic syndrome
J Vande Walle1, S Johnson2, E Harvey3, J Kincaid3
1University Hospital Ghent, Belgium; 2Medicus Economics, LLC, Boston, MA, USA; 3Aexion Pharmaceuticals, Cheshire, CT, USA

Introduction Atypical haemolytic uraemic syndrome (aHUS) is a severe, life-threatening disease requiring rapid treatment to inhibit complement-mediated thrombotic microangiopathy (TMA) and avoid irreversible organ damage. Four prospective clinical trials have reported the safety and efficacy of eculizumab (Ecu) in the treatment of aHUS [1,2]. We report data from a pooled analysis of these trials on renal function in patients starting Ecu within ≤7 days or >7 days after the current aHUS manifestation.

Methods Data from four phase 2, open-label, single-arm trials including both paediatric and adult patients with aHUS were pooled. Patients with a documented date of onset of current TMA manifestation and a baseline estimated glomerular filtration rate (eGFR) of <90 ml/
minute/1.73 m² were included. Changes from baseline in eGFR were analysed at study visits using a one-sample t test.

Results Data from 97 patients were analysed: median (range) age at enrolment was 29 (0 to 80) years; 62% of patients were females; median (range) duration of current manifestation to start of Ecu treatment was 23 (1 to 1,447) days; median (range) baseline eGFR was 15.9 (5.6 to 76.1) ml/minute/1.73 m². Ecu treatment was started in 21 patients in ≤7 days and 76 patients in >7 days after presentation with TMA. Median eGFR was 11 ml/minute/1.73 m² for the patients started within 7 days and 16 ml/minute/1.73 m² for those initiating >7 days. The mean change from baseline in eGFR for patients starting Ecu in ≤7 days and in >7 days after presentation with TMA were 57 and 23 ml/minute/1.73 m² at 1 year, respectively (Figure 1).

Conclusion This pooled analysis indicates that patients treated with Ecu within 7 days of a TMA manifestation had a greater improvement in eGFR over time than patients in whom treatment was delayed. These data show the importance of rapid diagnosis and treatment of aHUS for recovery of renal function.

P331 Evaluation of the quotient of the venoarterial carbon dioxide gradient and the arteriovenous oxygen content difference as a transfusion trigger parameter in hemodynamically stable patients with significant anemia
A Tahâ, A Shafe, M Mostafa, N Syed, H Hon, R Marktanner
Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates

Introduction Hemoglobin as the main trigger parameter for blood transfusion usually gives diminutive information about oxygen delivery and consumption. Although central venous oxygen saturation (ScvO₂) is an alternative parameter, its changes are unable to detect regional hypoxia. Our aim was to evaluate the quotient of the central venous-to-arterial carbon dioxide gradient (ΔPCO₂) and the arteriovenous oxygen content difference (Ca-cvO₂) as a valid transfusion trigger parameter in hemodynamically stable anemic patients to reduce the amount of potentially counterproductive erythrocyte transfusions [1].

Methods Forty-five postoperative patients admitted to our cardiac ICU were enrolled between January 2013 and September 2014. Three groups were defined according to the trend of blood loss over the surgical drains in the first 24 postoperative hours. Mild blood loss was defined as 500 to 1,000 ml/24 hours, moderate (1,000 to 1,500/24 hours) and severe (>1,500 ml/24 hours). In addition to the ΔPCO₂, the following parameters were monitored: Cl, CO, SVR, serum lactate, ScvO₂, and hemoglobin. Ca-cvO₂ was calculated and the ΔPCO₂/Ca-cvO₂ quotient was assessed for a total of 400 paired blood samples. All enrolled patients were hemodynamically stable. A retrospective analysis of this data was performed.

Results ΔPCO₂/Ca-cvO₂ showed significant correlation with the moderate and severe blood loss groups (P <0.01), while no significant correlation was detected in the mild blood loss group. The abnormality of the ΔPCO₂/Ca-cvO₂ was easy detectable and reflected intracapillary hemoglobin capacity decline and significantly improved after erythrocyte transfusions (P <0.005).

Conclusion Blood transfusions carry risks of adverse effects and should be carried out responsibly. Our findings suggest an additive and easily detectable transfusion trigger parameter (ΔPCO₂/Ca-cvO₂) providing physiological information on anemia-related altered oxygen extraction conditions and hence the indication for erythrocyte transfusions. However, additional studies are warranted to confirm these findings.

P332 Red blood cell transfusion in patients with traumatic brain injury: a systematic review
A Boutin 1, M Chasse 1, M Shemilt 1, F Lauzier 1, L Moore 1, R Zarychanski 1, J Lacroix 1, DA Fergusson 1, D Griesdale 1, P Desjardins 1, AF Turgeon 1
1Université Laval, Quebec, QC, Canada; 2University of Manitoba, Winnipeg, MB, Canada; 3Université de Montréal, QC, Canada; 4Ottawa Hospital Research Institute, Ottawa, ON, Canada; 5University of British Columbia, Vancouver, BC, Canada

Introduction We aimed to evaluate the frequency of red blood cell (RBC) transfusion in patients with traumatic brain injury (TBI) as well as determinants and outcomes associated with RBC transfusion in this population.

Methods We conducted a systematic review of cohort studies and trials of patients with TBI. We searched Medline, Embase, The Cochrane Library and BIOSIS databases from their inception up to 30 June 2014. We selected cohort studies and RCTs of adult patients with TBI reporting data on RBC transfusions. We extracted data related to demographics, baseline characteristics, blood product use and any relevant clinical patient-oriented outcome. Cumulative incidences of transfusion were pooled through random effect models with a DerSimonian approach, after a Freeman–Tukey transformation to stabilize variances. To evaluate the association between RBC transfusion and potential determinants as well as outcomes, we pooled risk ratios or mean differences with random effect models and the Mantel–Haenszel method. Sensitivity and subgroup analysis were planned a priori.

Results We identified 21 eligible studies (16,951 patients). After pooling data from the 20 included cohort studies (16,884 patients), at least around 33% (95% CI: 27 to 39; P: 97.8%) of patients with TBI in published reports received transfusions at some point during their hospital stay. In a post hoc analysis of one RCT comparing transfusion strategies, 82% of patients were transfused RBCs. Thresholds for transfusion were rarely available and varied from 6 to 10 g/dl. From raw data, Glasgow Coma Scale scores were lower in patients who were transfused than those who were not (three cohort studies; n = 1,371; mean difference of 1.38 points (95% CI: 0.86 to 1.89); P = 12%). Mortality was not significantly different among transfused and nontransfused patients both in univariate and multivariate analyses. Hospital length of stay was longer among patients who were transfused (three studies; n = 455; mean difference 9.58 days (95% CI: 3.94 to 15.22); P = 74%). Due to the observational nature of included studies, results should be considered cautiously due to the high risk of confounding.

Conclusion RBC transfusion is frequent in patients with TBI, but practices varied widely in cohort studies in this population. The paucity of data precludes definitive conclusions and highlights the lack of clinical evidence guiding transfusion strategies in TBI.

P334 Red blood cell transfusion is associated with an increased mortality in critically ill surgical patients
A Pinypatpong, O Chaiwat, S Kongpayeepong
Siriraj Hospital, Bangkok, Thailand

Introduction The aim of this study is to explore the association between red blood cell transfusion (RBCT) and mortality in Thai critically ill surgical patients.
**Methods** This study was a part of the multicenter, prospective, observational study performed in nine surgical intensive care units (SICUs) across the nation between April 2011 and November 2012 [1]. This study included adult patients admitted to the SICUs after surgery. Patients were categorized into transfusion and no transfusion groups according to whether or not they received RBCT at any time during SICU stay. Demographic data, clinical outcomes as well as SICU and hospital length of stay (LOS) and SICU and hospital mortality were collected. Patients were followed for up to 28 days or until discharge from the SICUs. The primary endpoint was hospital mortality. Data were compared between groups and logistic regression analysis was performed to determine whether RBCT was an independent risk factor of hospital mortality. In addition, patients were matched between groups based on the propensity score of the requirement of RBCT and were then compared.

**Results** Overall, 966 of 2,374 (40.8%) patients received RBCT. Transfused patients, when compared with those without RBCT, had more frequency of admission after emergency surgery, higher APACHE II score, higher SOFA score, higher number of organ dysfunctions and lower hemoglobin level at admission. When compared with patients without RBCT, those with RBCT had more frequency of all adverse events including infection, AKI, ALI/ARDS and MI, and longer SICU and hospital LOS. Both SICU and hospital mortality were also higher in the transfusion group compared with the no transfusion group (9.4% vs. 1.6% and 13.7% vs. 3.6%, both P < 0.001, respectively). The logistic regression analysis showed that RBCT was an independent risk factor of hospital mortality with odds ratio of 1.60 (95% CI 1.05 to 2.45). In the propensity-score matched cohort of 852 patients, when compared with patients without RBCT, transfused patients had more frequency of adverse events including infection and AKI, longer SICU and hospital LOS and higher hospital mortality (7.5% vs. 4.0%, P = 0.027).

**Conclusion** This study showed that RBCT was associated with increased morbidity and mortality in critically ill surgical patients. These results supported the restrictive strategy of RBCT suggested by more recent studies.

**Effect of the haemoglobin level on neurologic outcome in patients with severe traumatic brain injury**

K Balvers1, MR Wirtz1, C Rourke1, S Eaglestone1, K Brohi1, S Stanworth3, C Gaarder4, JC Goslings1, NP Juffermans1

1Academic Medical Center, Amsterdam, the Netherlands; 2Blizard Institute, Queen Mary University of London, UK; 3John Radcliffe Hospital, Oxford, UK; 4Oslo University Hospital, Oslo, Norway

**Introduction** Anaemia in patients with severe traumatic brain injury (TBI) may worsen neurologic outcome. The aim of this study was to determine the association of haemoglobin level (Hb) with neurologic outcome and to determine a transfusion threshold which may be used in future transfusion trials aimed at improving neurologic outcome in TBI patients.

**Methods** A substudy of the prospective multicentre Activation of Coagulation and Inflammation in Trauma (ACIT) II study was performed on subjects recruited between January 2008 and December 2014. All adult trauma patients admitted to a level 1 trauma centre with severe traumatic brain injury (AIS head ≥3), ICU admission and available Hb levels on admission were selected for analysis. The primary outcome was the cognitive functioning of patients as determined by an estimated Glasgow Outcome Scale (GOS) on discharge. Anaemia was defined as a Hb level of ≤9 g/dl (severe anaemia) or ≤10 g/dl (moderate anaemia) within the first 24 hours post injury. Multivariate logistic regression models were used to determine the association between anaemia and neurologic outcome. The receiver operating characteristic curve and the Youden Index were used to determine an optimal transfusion threshold.

**Results** Of a total of 261 TBI patients, 61 patients (23%) fell below the threshold for severe anaemia and 101 patients (39%) had moderate anaemia within the first 24 hours. In a model adjusted for all relevant confounders, a Hb level of ≤9 g/dl was associated with a poor neurologic outcome (OR = 2.572, 95% CI = 1.058 to 6.250), whereas an Hb level of ≤10 g/dl was not. A Hb level of ≤10.3 g/dl had a sensitivity of 82% and a specificity of 62% to predict poor neurologic outcome in TBI patients.

**Conclusion** In TBI patients a Hb level of ≤9 g/dl is associated with poor neurologic outcome. A transfusion threshold of ≤10.3 g/dl may be a reasonable target to be tested in future transfusion trials aimed at improving neurologic outcome of TBI patients.

**Acknowledgements** All of the authors are affiliated members of the International Trauma Research Network (INTRN) and as such this work represents a combined output resulting from this Network.
Methods: We performed a 1-day retrospective review in June of blood request forms submitted to the cross-match laboratory, followed by a 14-day prospective review in September 2014. Group and save requests were excluded. Each form was audited against the American Association of Blood Banks (AABB) minimum standards for content of a blood request form. Analysis was performed with Fisher’s exact test for nominal data and t test for continuous data.

Results: A total of 1,163 blood requests were reviewed, 51 from CDH and 1,112 from other wards. Eighteen forms from CDH (35%) and 22 from other wards (2%) met all minimum AABB standards (P < 0.0001). The mean number of standards met on the requests from CDH and the rest were 11.25 (SD 0.93) and 8.87 (SD 1.75) respectively (P < 0.0001). Considering all blood requests, the standards met in order from least to most were: signature of requesting doctor (36%), urgency of request (43%), hospital number (59%), indication for transfusion (62%), type of product requested (72%), requesting doctor’s name (78%), age or date of birth of patient (84%), gender of patient (89%), quantity of products requested (90%), date form was completed (90%), patient’s ward (95%), and patient’s full name (100%).

Conclusion: The audit revealed an important system failure impacting on efficacy and safety of transfusion practice at UTH. Full patient identifiers, as well as vital information such as the indication and urgency requested are rarely filled in, which are crucial for the blood bank to prioritise the release of blood products. The audit shows that practice may be significantly improved by a cheap intervention such as a standardised blood request form meeting international standards. Acknowledgements: UK aid, THET.

Inadequate monitoring risks safety of blood transfusion in rural Zambia
O’Todd1, K Sikwewa1, J Kamp1, J Hodt Rasmussen1, K Mortensen1, S Kudsk-Iversen2
1 St Francis Hospital Katete, Zambia; 2 University College Hospital, London, UK

Introduction:
In Zambia, supply of blood is insufficient to meet clinical need, on a national level. Paradoxically, blood is also more often transfused unnecessarily in this setting. The Zambian National Blood Transfusion Service is currently scaling up voluntary blood donation and supply systems, and requires hospitals to improve blood transfusion safety. At a rural district hospital in Zambia, we audited practice and surveyed knowledge amongst staff using standards established in national guidelines.

Methods:
A retrospective audit over 2 months of all blood transfusion forms at St Francis Hospital, Eastern Province, Zambia. Respective patients’ notes were reviewed for: record of observations during transfusion; patient demographics; and length of stay. We surveyed nurses’ attitudes, confidence and knowledge in relation to blood transfusion standards.

Results:
In May and June 2014, 457 requests were made for blood, of which 157 (34%) received blood transfusion, of which 108 (69%) had records of observations available. The audit demonstrated that requests were mostly complete (90%), but urgency was indicated in only 32%. The matching of blood to patient by more than one nurse was recorded amongst 66% of cases. Only 2% of transfusions met minimal requirements for transfusion reaction monitoring. Of nurses surveyed (n = 20), most were experienced in their post (mean 7.3 years, range 2 weeks to 20 years). Nurses rated themselves as highly confident in handling blood transfusions and identifying and dealing with transfusion reactions. However, 90% believed they could identify all transfusion reactions by measuring temperature alone, and 25% would measure temperature only as a parameter to monitor the transfusion, even in ideal settings. Most knew to check observations before, 15 minutes after the start of transfusion and then hourly thereafter (88%); but only 10% would check at the start, at completion and 4 hours after completing transfusion. The most frequently reported reason for not doing observations was time pressure on the ward (85%).

Conclusion:
In this setting, current practice is evidently inadequate to identify and prevent blood transfusion reactions. The survey revealed high confidence but patchy knowledge amongst nurses of the requirements. Better timing to transfuse at times when nursing staff numbers are higher, alongside compulsory training, may together represent potential low-cost interventions to improve blood transfusion safety.

P339
Effects of iron deficiency on transfusion requirements in critically ill patients: a preliminary observational study
M Aydogan, M Ucar, A Yücel, B Karakas, A Gok, T Togal
Inonu University, Malatya, Turkey

Introduction:
Critically ill patients often need blood transfusion, but no reliable predictors of transfusion requirements are available at ICU admission. We hypothesized that ICU patients admitted with iron deficiency may be at higher risk for developing anemia, requiring blood transfusion. The aims of this study were to determine the frequency of iron deficiency in ICU patients at admission and to investigate its relationship with transfusion requirements in ICU patients.

Methods:
Eighty-five patients admitted to the general ICU were enrolled in the prospective observational study. We studied 58 patients, after excluding those transfused on or before ICU admission. The patients’ age, gender, APACHE II score, diagnosis, severity score, presence of sepsis, ICU complications, ICU treatments, and transfusion-free interval were recorded. Iron deficiency was assessed on the basis of several parameters, including hemoglobin, hematocrit, levels of serum iron, iron-binding capacity, transferrin saturation, levels of ferritin, soluble transferrin receptor, hepcidin, C-reactive protein, and peripheral blood smear.

Results:
The mean age was 43.5 ± 5.7 years. Of 58 patients (38 male/20 female), 25 (43.1%) had iron deficiency with outcomes of blood samples used at ICU admission. The overall transfusion rate was 32.8%, being higher in iron-deficiency patients than in normal iron profile patients (42.3 vs. 14.9%, P = 0.001). After adjusting for severity of illness and hemoglobin level, iron-deficiency patients remained significantly associated with transfusion, with a hazard ratio of 4.2 (95% CI, 1.3 to 12.9, P = 0.001).

Conclusion:
Iron deficiency is common at ICU admission and is associated with higher transfusion requirements. These findings have important implications for transfusion practices in ICU patients.

P340
Value of thromboelastography in managing hypercoagulopathy in intensive care
J Aron, A Gibbon, C Ward, J Ball
St George’s Hospital, London, UK

Introduction:
This aim of this analysis is to explore the use of thromboelastography (TEG) in the management of hypercoagulation in the ICU. TEG allows the assessment of whole blood coagulation and fibrinolysis and hence can identify patients who are hypercoagulable.

Methods:
A prospective audit of TEG tests performed on patients being treated on a general surgical and medical ICU was conducted over a 2-month period.

Results:
Twenty-one out of 78 patients (26.9%) had one or more TEG criteria consistent with hypercoagulopathy. Admission diagnoses included trauma (37%), haemorrhage (23%), postoperative (23%) and sepsis (14.3%). Sixty-two per cent of patients with a primary diagnosis of trauma were in a hypercoaguable state. Hypercoagulopathy was suggested by an abnormally short R time in 16 patients (76%), an abnormal alpha angle in 17 cases (81%), a maximum amplitude >74 mm in nine cases (43%) and a high LY30 in one case. Procoagulant treatment was given to seven patients and five patients had received no coagulation modification prior to testing (Figure 1). Eight patients were receiving prophylactic anticoagulation and only one was receiving treatment-dose anticoagulation. A change in management...
Thromboelastography may detect hypercoagulation in early sepsis and improve anticoagulation during extracorporeal treatments

P341

Thromboelastography may detect hypercoagulation in early sepsis and improve anticoagulation during extracorporeal treatments

T Turanti, S Busatti, R Barchetta, AB Belli, S Martini, M Falco
Aurelia and European Hospital, Rome, Italy

Introduction During early sepsis, activation of the inflammatory response and coagulation occurs. Extracorporeal therapies are used to adsorb mediators, but the coagulation of filters is a drawback [1,2]. The aim of this study is to evaluate whether thromboelastography (TEG) may detect hypercoagulation and may improve anticoagulation during extracorporeal treatments.

Methods Twenty-four patients with early severe sepsis had a TEG monitoring at basal time (T0) and during three different extracorporeal treatments (T1): coupled plasma filtration (CPFA) with heparin infusion (Group A), CPFA with citrate infusion (Group B) and RRT with oXiris filter – heparin coated – and no heparin infusion (Group C). ANOVA test was used for the statistical analysis.

Results Table 1 presents the TEG values in early septic patients at T0. At T1, angle and MA decreased and r increased in Group A at difference with Group B and Group C (P < 0.01). In group C, LY 30 was higher than in Group A and B (P < 0.01).

*P < 0.01.

Conclusion In early sepsis, TEG monitoring may detect hypercoagulability. CPFA with heparin, but not CPFA with citrate and oXiris, is able to reverse hypercoagulability. OXiris may induce fibrinolysis. TEG detects alterations of coagulation during early sepsis and extracorporeal treatments.

References
Results Seventy-eight audit sheets were completed, of which 31 identified haemorrhage as the reason for admission. The mean age was 59.3 (range 21 to 90) and the mean APACHE II score was 18.23 (range 11 to 37). The main indications for TEG analysis included coagulopathy (64%) and ongoing haemorrhage (45%). As a result of performing TEG analysis, 23 (74%) patients had a documented change in their management. Ten patients did not require any further administration of blood products, which they would have received based on conventional laboratory results. The information gained from TEG also resulted in the omission of anticoagulation in three patients, and with a further two patients anticoagulation increased.

Conclusion TEG aids prompt rationalisation of blood products and titration of anticoagulation in the bleeding patient. TEG identifies a number of patients who required administration of platelets and other procoagulants which would not have been identified by conventional methods. Several patients would have also received inappropriate transfusions which has both cost and resource implications, alongside the potential adverse effects on patients. We recognise that further research is needed to clarify the overall efficacy of TEG in the bleeding patient.

Utilisation review of thromboelastography in intensive care
J Aron, A Gibbon, C Ward, J Ball
St George’s Hospital, London, UK

Introduction This review aims to assess the value of thromboelastography (TEG) on the general ICU, which has not been previously demonstrated. TEG is a near-patient assessment of whole blood coagulation and fibrinolysis, which reduces transfusion requirements during cardiothoracic surgery and liver transplantation.

Methods A prospective audit of TEG tests performed on patients being treated on a general ICU was conducted over 2 months.

Results A total of 332 TEG tests were performed with a failure rate of 29.8%. Seventy-eight audit sheets were collected. Mean patient age was 59.3 years and mean APACHE II score was 18.1. Admissions included trauma (33.0%), perioperative (43.6%), haemorrhage (42.3%) and sepsis (21%). Standard tests of coagulation demonstrated 22 deficits in trauma (33.0%), perioperative (43.6%), haemorrhage (42.3%) and ongoing haemorrhage (29.8%). Seventy-eight audit sheets were collected. Mean patient age treated on a general ICU was conducted over 2 months.

Mean patient age treated on a general ICU was conducted over 2 months.

Results A total of 332 TEG tests were performed with a failure rate of 29.8%. Seventy-eight audit sheets were collected. Mean patient age was 59.3 years and mean APACHE II score was 18.1. Admissions included trauma (33.0%), perioperative (43.6%), haemorrhage (42.3%) and sepsis (21%). Standard tests of coagulation demonstrated 22 deficits in trauma (33.0%), perioperative (43.6%), haemorrhage (42.3%) and ongoing haemorrhage (29.8%). Seventy-eight audit sheets were collected. Mean patient age treated on a general ICU was conducted over 2 months.

Evaluation of fixed dose four-factor prothrombin complex concentrate for warfarin reversal at a level 1 trauma center
H Drane, J Jancik, J Gerlin, M McCarthy
Hennepin County Medical Center, Minneapolis, MN, USA

Introduction FDA-approved dosing of four-factor prothrombin complex concentrate (4F-PCC) in the USA is based on an INR and weight; however, there are data suggesting that a fixed dose of 4F-PCC may be sufficient for INR reversal and hemostasis [1,2]. The objective of this study was to assess the efficacy and safety of a fixed dose of 1,500 units of 4F-PCC. Historically, warfarin reversal included a combination of factor IX complex, vitamin K, and fresh frozen plasma (FFP). Using a fixed dose of 4F-PCC may also provide significant cost savings when compared with traditional dosing.

Methods This retrospective chart review compared 26 admitted adults who received a fixed dose of 1,500 units 4F-PCC with 26 patients who received a combination of factor IX complex and vitamin K, with or without FFP, for warfarin reversal from 1 January 2012 to 1 November 2014. Primary outcomes included reversal to an INR of <2 and reversal to an INR of <1.6. Secondary outcomes included ICU and hospital length of stay (LOS), change in INR, INR nadir, potential cost savings from 4F-PCC versus traditional dosing, and major adverse effects.

Results The INR was reduced to <2 in 100% of patients in the 4F-PCC group versus 84.6% of patients in the factor IX group (P < 0.05). The INR was reduced to <1.6 in 90.8% of patients in the 4F-PCC group versus 50% in the factor IX group (P < 0.05). Mean pre-reversal INRs were 3.5 and 4 and ranged from 1.1 to 10 and from 1.3 to 10 in the 4F-PCC and factor IX group respectively (P = 0.29). On average, a medication cost savings of US$802.63 dollars per patient was calculated from using a fixed 1,500 unit dose over traditional dosing of 4F-PCC. There was a trend toward a shorter mean ICU LOS in the 4F-PCC group when compared with the factor IX group (5.8 vs. 2.8 days) and shorter mean hospital LOS (10.7 vs. 5.7 days), although neither outcome was statistically significant. No difference in adverse event rates was observed.

Conclusion A fixed dose of 1,500 units of 4F-PCC was significantly more effective at lowering the INR to a threshold of less than either 2 or 1.6 when compared with a combination of factor IX complex and vitamin K with or without FFP. Further research is needed to investigate clinical outcomes and a possible reduction in ICU and hospital LOS.

Four-factor prothrombin complex concentrate (Beriplex® P/N) is superior to three-factor prothrombin complex concentrate for reversal of coumarin anticoagulation
E Herzog, F Kaspereit, W Krege, P Niebl, G Dickneite
CSL Behring GmbH, Marburg, Germany

Introduction The study was conducted as a head-to-head comparison of a four-factor prothrombin complex concentrate (4F-PCC) and two different three-factor PCCs (3F-PCC) for effective reversal of vitamin K antagonist (VKA)-induced anticoagulation using an established rat model of acute bleeding [1]. The 4F-PCC (containing the human coagulation factors II, VII, IX and X) is indicated for the urgent reversal of acquired coagulation factor deficiency induced by VKA therapy in adult patients with acute major bleeding. In contrast, the 3F-PCCs (containing factors II, IX, X and only minimal VII) are indicated for the prevention and control of hemorrhagic episodes in hemophilia B patients. Nevertheless, the use of 3F-PCC for correcting hemostasis following warfarin overdose has been discussed but the lack of factor VII in these 3F-PCC products has raised questions about efficacy.

Methods Rats received an oral dose of 2.5 mg/kg phenprocoumon. At 15.75 hours post dosing, animals were treated with a single intravenous dose of saline, 4F-PCC (Beriplex® P/N, Kcentra®; CSL Behring) or 3F-PCC (Bebulin® VH; Baxter and Profilin® SD, Grifols). Study endpoints included bleeding following tail clip, activated partial thromboplastin time (aPTT), and prothrombin time (PT). In addition, the plasma levels of vitamin K-dependent coagulation factors were determined.

Results Acute coumarin anticoagulation of rats induced a rise in median bleeding time by ≥2-fold from an average of 823 to 1,800 seconds (maximum observation period) compared with untreated animals. In parallel, PT and aPTT were prolonged from 8.9 to 29.9 seconds and from 14.5 to 25.5 seconds, respectively. Treatment with 4F-PCC was able to fully and statistically significantly reverse bleeding, achieving average bleeding times of 676 seconds. In parallel, the elevation in PT was reduced to ≤15.1 seconds. In contrast, the two 3F-PCC products were not or only partially able to reduce coumarin-induced bleeding with average bleeding times of 1,398 and 1,708 seconds post treatment, respectively. This also correlated with inferior reductions in PT which achieved minimum levels of 23.8 and 29.5 seconds, respectively. There was no reduction in aPTT seen for any treatment option.

Conclusion In conclusion, this first direct comparison of 4F-PCC and 3F-PCCs for the reversal of VKA anticoagulation in a rat model of acute bleeding suggests that replenishment of all four vitamin K-dependent coagulation factors including factor VII as achieved using a 4F-PCC may result in superior efficacy compared with the use of 3F-PCCs.

Four-factor prothrombin complex concentrate (Beriplex® P/N) mediated reversal of apixaban-induced bleeding in a rabbit model
E Herzog, F Kaspereit, W Krege, J Mueller-Cohns, B Doen, P Niebl, G Dickneite
CSL Behring GmbH, Marburg, Germany

Introduction This study assessed whether a four-factor prothrombin complex concentrate (4F-PCC; Beriplex®/Kcentra®; CSL Behring) can effectively reverse bleeding associated with the direct oral factor Xa inhibitor apixaban in an established in vivo rabbit model [1,2].

Methods For dose-finding purposes, anesthetized rabbits were treated with a single intravenous dose of apixaban (800 to 1,600 μg/kg). In a subsequent study phase, anesthetized rabbits were treated with apixaban (1,200 μg/kg) followed by 4F-PCC (6.25 to 100 IU/kg). Bleeding signals were quantified following a standardized kidney incision by measurement of the volume of blood loss and time to hemostasis over an observation period of 30 minutes. Blood samples were collected for monitoring of coagulation parameters.

Results Dose-dependent increases in time to hemostasis and total blood loss were observed post apixaban administration with maximum bleeding signals seen at 1,200 μg/kg. Treatment with 4F-PCC resulted in a statistically significant reversal in apixaban-induced bleeding time (all doses) and volume (doses ≥12.5 IU/kg). Of the coagulation parameters measured, thrombin generation initiated using phospholipids only was the in vitro coagulation parameter most sensitive to 4F-PCC-mediated bleeding reversal, although statistically significant 4F-PCC-mediated reductions in the prothrombin time and whole blood clotting time were also observed.

Conclusion In conclusion, 4F-PCC treatment effectively decreased apixaban-induced hemorrhage at a clinically relevant dose range.

Beneficial effects of prehospital versus immediate in-hospital blood products during resuscitation in two models of severe military injury
S Watts, G Nordmann, C Wilson, A Carter, H Poon, E Kirkman
Dstl, Salisbury, UK

Introduction Acute trauma coagulopathy (ATC) is seen in 30 to 40% of severely injured trauma casualties. Early use of blood products is thought to attenuate ATC. This study determined the potential impact
of prehospital versus immediate in-hospital packed red blood cells and fresh frozen plasma (PRBC:FFP) in two models of severe battlefield injury.

**Methods** This is a prospective randomised controlled trial using in vivo models of injury conducted in accordance with the Animals (Scientific Procedures) Act, 1986. Two injury strands were investigated in 43 terminally anaesthetised Large White pigs: whole body blast exposure (Bl) or no blast (ShBl) plus soft tissue injury and haemorrhage. Thirty minutes later animals were randomly allocated to a 60-minute simulated prehospital hypotensive resuscitation with either PRBC:FFP (1:1 ratio) or 0.9% saline (Early and Late groups respectively). This was followed by 150 minutes of simulated in-hospital resuscitation with a revised normotensive target whereby PRBC:FFP was initiated in the Late group and continued in the Early group.

**Results** In the ShBl injury strand there was a significant reduction in ATC in Early compared with Late PRBC:FFP treatment (TEG R and K times). PRBC:FFP, Prehospital base deficit (BD) was significantly attenuated in Early (mean BD ± SD: 123 ± 58 ml/kg vs. 188 ± 85 ml/kg). BD improved in both Early and Late treatment groups during the in-hospital phase but remained greater in the Late group throughout (P <0.001). In the Bl injury strand the trend in coagulation was similar to that seen in the ShBl injury strand (but the differences between Early and Late did not attain statistical significance). By contrast, Early versus Late PRBC:FFP treatment did not result in a difference in BD in the Bl strand. Finally, there was no difference in the total amount of PRBC:FFP used between the two treatments in either injury strand, but in both injury strands the Early treatment groups required significantly less saline (P <0.001).

**Conclusion** Prehospital use of PRBC:FFP may attenuate ATC and improve physiological status. Furthermore, the amount of crystalloid may be reduced with potential benefit of reducing the third-space effect and later tissue oedema.

**Efficacy of idarucizumab, prothrombin complex concentrate (PCC) and activated PCC to reverse the anticoagulatory potential of dabigatran in a porcine polytrauma model**

M Honickel1, T Braunsschweig1, J Van Ryn1, R Rossaint1, O Grottke1

1RWTH Aachen University Hospital, Aachen, Germany; 2CardioMetabolic Diseases Research, Boehringer Ingelheim GmbH & Co KG, Biberach, Germany

**Introduction** The anticoagulant effect of dabigatran can be reversed with idarucizumab or PCCs in porcine blood in vitro [1]. However, the impact on clinical parameters such as blood loss is not known. Thus, this study assessed the efficacy of idarucizumab in comparison with PCC and aPCC in dabigatran-anticoagulated swine following polytrauma on clinically relevant endpoints.

**Methods** After ethical approval, 28 male pigs were administered dabigatran etexilate (30 mg/kg twice daily p.o.) for 3 days. Dabigatran was administered intravenously in anaesthetised animals on day 4 to achieve consistent high concentrations. Animals were randomised to receive idarucizumab (60 mg/kg, n = 7), PCC (50 U/kg, n = 7), aPCC (50 U/kg, n = 7) or placebo (n = 7). Intervention started 12 minutes after bilateral femur fractures and a standardised blunt liver injury. The primary endpoint was blood loss (observation period 300 minutes). Further, histopathology, haemodynamics and several coagulation variables were also assessed. Data were analysed by repeated-measures ANOVA (mean ± SD).

**Results** Dabigatran levels were comparable between groups (571 ± 174 ng/ml) and resulted in altered coagulation variables. Blood loss was comparable 12 minutes post trauma between groups (801 ± 49 ml) and increased to 3,816 ± 236 ml in anticoagulated control animals post injury. Idarucizumab treatment reduced total blood loss to 1,086 ± 55 ml (P <0.005 vs. all), aPCC to 1,639 ± 104 ml (P <0.05 vs. control) and PCC to 1,797 ± 80 ml (P <0.05 vs. control) after 5 hours. All animals in the intervention groups survived, whereas control animals died within the observation period (mean survival: 89 minutes, range: 62 to 112 minutes). In histopathology no signs of thromboembolic events were present. Altered coagulation variables returned to baseline levels after idarucizumab application and were also significantly, although inconsistently and to a lesser extent, ameliorated following PCCs.

**Conclusion** All medical interventions were associated with reduced blood loss and increased survival. However, idarucizumab, a specific antidote to dabigatran, reduced total blood loss more prominently and normalised coagulation parameters to a greater degree as compared with either PCC or aPCC.

**Coagulation support algorithm with rapid TEG and functional fibrinogen TEG in critical bleeding: more results and less time**

E De Blasio, C Pellegrini, A Federico, V Rocco, M Fumi, Y Pancione, S Sale, D Liberti

Hospital G. Rummo, Benevento, Italy

**Introduction** Early coagulation support is essential in massively bleeding patients. A Coagulation Support Algorithm (CSA), integrating rapid TEG (r-TEG) and functional fibrinogen TEG (f-TEG) could shorten the time to a tailored treatment (Figure 1).
Table 1 (abstract P352). Comparison of time to results

Data presented as mean ± SD. ACT, activated clotting time; CSAT, Coagulation Support Algorithm total time; SCT, standard coagulation tests; TMA, time to maximum amplitude. r: r-TEG versus k-TEG, P = 0.0000003; r-TEG versus SCT, P = 0.000000001; k-TEG versus SCT, P = 0.000000009; TMA: r-TEG versus k-TEG, P = 0.0001; r-TEG versus SCT, P = 0.00000004; k-TEG versus SCT, P = 0.000002; ACT versus r of k-TEG (seconds), P = 0.000004; CSAT versus k-TMA, P = 0.00000005.

Methods
A retrospective comparison of the time to available TEG and Standard Coagulation Tests (SCT: INR, aPTT, fibrinogen level) results in two groups of bleeding and coagulopathic patients using citrate kaolin-TEG (k-TEG) or the CSA protocol (r-TEG/ff-TEG). Statistical analysis was performed with Student’s t test for unpaired samples.

Results
Twenty-three patients for each k-TEG and CSA group were compared. The time to available results was shorter using the CSA protocol in comparison with k-TEG (Table 1). The differences were both statistically (P < 0.00001) and clinically (mean reduction time 21 minutes) significant. SCT needed the longest time to obtain the final results.

Conclusion
The implementation of a CSA, including r-TEG and ff-TEG, could shorten the time to a targeted treatment in critically bleeding patients.

Use of albumin in spontaneous bacterial peritonitis is cost-effective
A Farrugia1, M Bansal2, P Caraceni3
1University of Western Australia, Perth, Australia; 2Thought Semantics LLC, Sterling, VA, USA; 3University of Bologna, Italy

Introduction
Assessing the cost-effectiveness of therapeutic interventions is increasingly crucial for health decision-making. Spontaneous bacterial peritonitis (SBP) is one of the major complications of liver cirrhosis. The use of albumin in conjunction with antibiotics has been supported indications for effective resource allocation. Supported indications include sepsis, areas of hepatic diseases and coronary artery bypass grafts (CABG). Latent therapeutic demand (LTD) [1] is the underlying evidence-based demand ensuring ample supplies of drugs are available and affordable. Estimating the LTD would assist decision-making and resource allocation.

Methods
A decision tree (TreeAge®) (Figure 1) was populated from published sources for clinical, cost and epidemiologic variables. The perspective taken was that of the US payer. The robustness of the model was checked using one-way and probabilistic sensitivity analyses. The clinical course was followed for 3 months or until death. Total medical costs and quality-adjusted life years (QALYs) [2] were calculated.

Table 1 (abstract P353). Results of the cost-effectiveness model

<table>
<thead>
<tr>
<th>Treatment</th>
<th>QALYs</th>
<th>Total medical costs ($)</th>
<th>Total costs/ QALY ($)</th>
</tr>
</thead>
<tbody>

<td>3,111</td>
</tr>
<tr>
<td>Antibiotics</td>
<td>1.48</td>
<td>7,682</td>
<td>5,182</td>
</tr>
</tbody>
</table>

Results
Total costs were decreased when using albumin, and the improved survival resulted in an additional QALY for patients on albumin, decreasing the cost per QALY. See Table 1 and Figure 2.

Conclusion
The use of albumin in the treatment of SBP is cost-effective.

Estimation of the latent therapeutic demand for albumin in the USA: a focus on three indications
A Farrugia1, M Bansal2
1University of Western Australia, Perth, Australia; 2Thought Semantics LLC, Sterling, VA, USA

Introduction
The use of albumin in therapeutics is controversial in several areas and requires assessment based on evidence for effective resource allocation. Supported indications include sepsis, areas of hepatic diseases and coronary artery bypass grafts (CABG). Latent therapeutic demand (LTD) [1] is the underlying evidence-based demand ensuring ample supplies of drugs are available and affordable. Estimating the LTD would assist decision-making and resource allocation.

Methods
A decision tree (TreeAge®) (Figure 1) was populated from published sources for clinical, cost and epidemiologic variables. The perspective taken was that of the US payer. The robustness of the model was checked using one-way and probabilistic sensitivity analyses. The clinical course was followed for 3 months or until death. Total medical costs and quality-adjusted life years (QALYs) [2] were calculated.

allocation, but many of the clinical and epidemiologic variables are subject to uncertainty. Decision analysis [2] may assist in generating an assessment of the demand for albumin.

Methods A decision analysis model was constructed using Excel. The model is based on the relationships of the epidemiological and clinical factors shown in the influence diagram (exemplified in Figure 1 for sepsis). Data for the individual factors were obtained from the literature. One-way sensitivity analysis was used to generate Tornado diagrams (exemplified in Figure 2 for albumin use in sepsis) to determine the relative contribution of different factors to the LTD. Probabilistic sensitivity analysis was used to generate a probability distribution and calculate a mean level for the LTD of each indication.

Results On average, albumin use was calculated as 104 g per 1,000 inhabitants in severe sepsis, 157 g per 1,000 inhabitants in liver diseases and 61 g per 1,000 inhabitants in CABG. This shows a total LTD of 322 g per 1,000 use of albumin in the US annually.

Conclusion Albumin consumption in the USA currently averages 479 g per 1,000 population [3]. Hence, the LTD of these three evidence-based indications represents 67% of current usage. Further work is needed to assess the LTD for albumin in other, less well-defined areas.

Introduction Adequate fluid therapy is essential to the care of septic patients, aiming to optimize oxygen delivery without compromising microcirculation. In recent years, a few studies have suggested that albumin may be superior when compared with crystalloids in severe cases of septic shock. However, there are no data in the first hours of resuscitation. The aim of this study is to evaluate whether albumin 4% solution compared with lactated Ringer decreases 30-day mortality in cancer patients with septic shock.

Methods The Lactated Ringer Versus Albumin in Early Sepsis Therapy (RASP) study is a prospective, randomized, double-blind and controlled trial, with 360 patients. Until November 2014, at the Cancer Institute of University of São Paulo, we enrolled 110 patients with cancer and septic shock to receive as resuscitation fluid in the first 12 hours of ICU an admission bolus of albumin 4% solution or lactated Ringer. The primary outcome was 30-day mortality. Secondary outcomes include ICU mortality, ICU and hospital length of stay, 90-day mortality, daily SOFA score, rates and length of mechanical ventilation, renal replacement, needing of vasopressor drugs, status performance and fluid balance.

Results From 650 eligible patients, 110 patients were included in the study – 50 patients in the albumin group and 60 in the Ringer group. The mean age was 63 (57 to 70) years in the albumin group and 61 (51 to 71) in the Ringer group, P = 0.508. Most patients were male (58% in the albumin group vs. 56.1% in the Ringer group, P = 0.846). The ECOG was similar between the albumin and Ringer groups ([0] 26% vs. 8%, (1) 38% vs. 36.8%, (2) vs. 38.6%, (3) 16% vs. 15.8%, P = 0.05). The SAPS 3 admission score was 51 ± 13 in the albumin group and 49 ± 10 in the Ringer group, P = 0.492. The total amount of administered fluid in the first 12 hours of resuscitation was 1,000 ml (1,000 to 1,500) in the albumin group and 1,000 ml (1,000 to 1,000) in the Ringer group, P = 0.59. The 12-hour fluid balance was 1,053 ml (385 to 1,700) in the albumin group and 990 ml (200 to 1,525) in the Ringer group. The 30-day mortality was similar in both groups (60% in the albumin group and 50.9% in the Ringer group, P = 0.34). No significant differences in the other secondary outcomes were observed between the two groups.

Conclusion In cancer patients with septic shock, resuscitation with albumin 4% as compared with lactated Ringer did not improve the rate of survival at 30 days.

Reference
120 minutes after pump start. SID, base excess (BE) and total weak acids (Atot) were calculated.

Results We enrolled 20 patients (23 priming procedures – RL, n = 8; NS, n = 8; Solution X, n = 7). ECMO was initiated for ARDS (45%), bridge to lung transplant (25%), acute graft failure after transplant (15%), and acute on chronic respiratory failure (15%). Average priming volume was 10 ± 5 ml/kg; patients’ baseline HC0– was 28 ± 6 mEq/l. During the first 2 hours after ECMO initiation, arterial pH raised similarly in all groups (P = 0.39) due to CO2 removal. In contrast, BE decreased starting after 5 minutes in both the NS and RL groups. (BE variation, –2.2 ± 1.7 and –1.9 ± 1.3 mEq/l; P < 0.001 vs. baseline; P = 0.04 for interaction, two-way ANOVA, 2-hour period). No BE changes were observed in the Solution X group (0.3 ± 0.8 mEq/l). In the NS group, BE reduction was associated with a reduction in SID (from 39 ± 8 to 34 ± 6 mEq/l at 5 minutes, P = 0.008), entirely due to an increase in Cl0– (103 ± 7 vs. 108 ± 6 mEq/l, P = 0.001). In the RL group, BE and SID reductions (40 ± 8 vs. 36 ± 8 mEq/l, P = 0.008) were associated with an increase in both Cl0– (107 ± 6 vs. 107 ± 7 mEq/l, P = 0.01) and lactate (1.4 ± 0.6 vs. 2.2 ± 1.0 mEq/l, P = 0.008). No changes were observed in other electrolyte concentrations. Dilution did not differ between groups (P = 0.25 for Atot variation). The acidifying effect of NS and RL was amplified in patients with higher baseline HC0–.

Conclusion As compared with NS and RL, the use of a novel balanced solution with a SID equal to the patient HC0– level for ECMO priming uniquely avoids the addition of metabolic acidosis to patients with uncompensated hypercapnia.

Intraoperative use of gelatin in living donor liver transplantation and postoperative acute kidney injury. Kidney injury
HK Atalan1, B Gucyetmez2, S Aslan1, M Berktas3, KY Polat1
1Atasehir Memorial Hospital, Istanbul, Turkey; 2International Hospital, Istanbul, Turkey; 3Kappa Consulting, Istanbul, Turkey

Introduction The aim of our study is to investigate the effect of intraoperative use of gelatin in living donor liver transplantation on postoperative acute kidney injury (AKI). It has been demonstrated that ischemia and chloride-liberal fluid management cause AKI in liver transplantation [1]. Gelatin has minimal side effects on renal functions [2]; however, it might be a reason for postoperative AKI.

Methods A total of 154 liver transplantation patients were retrospectively evaluated between September 2011 and September 2013, and among these, 128 patients were included in the study. The patients who were under 18 years old, transplanted from cadaveric donors and needed preoperative renal replacement therapy were excluded. The patients were divided into two groups as GI (without gelatin administration) and GII with gelatin administration). The patient’s age, gender, actual body weight, diagnoses, MELD score, APACHE II score, duration of operation, total clamping time, noradrenaline infusion rate, amount of erythrocyte suspension, fresh frozen plasma (FFP) and thrombocyte suspension used, intraoperative fluid balance, intraoperative and total clamping diuresis, serum creatinine levels on the postoperative 1st, 2nd, 4th and 7th days, duration of mechanical ventilation, length of ICU and hospital stay, hospital and 1-year mortality rate were recorded. The changes in creatinine levels on the 1st, 2nd, 4th and 7th days were evaluated according to the KDIGO guideline for AKI [3].

Results In total, 128 patients were categorized as GI (58, 45%) or GII (70, 55%). Total clamping time, intraoperative diuresis, intraoperative crystalloid use, intraoperative fluid balance, operation bleeding, erythrocyte suspension, FFP and thrombocyte suspension usage and postoperative lactate levels of GI were statistically significantly higher than GI (P <0.001 for each). According to the KDIGO guideline, AKI in GI on the 1st, 2nd, 4th and 7th days (11.4%; 20%; 24.3%; 17.1%) was statistically significantly higher than GI (P <0.001 for each).

Conclusion In patients who received gelatin, kidney dysfunction in the postoperative period was observed more frequently. Also in this group, total clamping time was longer and amount of blood products used during surgery was more than the other group. Which of these factors is associated with AKI has to be revealed with further studies.

Incidence of acute kidney injury in critically burned patients resuscitated with crystalloid and colloid according to parameters of transpulmonary thermomodulation, diuresis and lactic acid
P Extremera Navas, M Sanchez Sanchez, I Pozuelo Echeagaray, A Agrifoglio Rotaechae, A Robles Caballero, A Garcia de Lorenzo Hospital Universitario La Paz, Madrid, Spain

Introduction The purpose was to study the incidence of acute kidney injury (AKI) according to RIFLE and AKIN criteria in critically ill burn patients resuscitated with Ringer’s solution and supplements of lower molecular weight hydroxyethyl starch (HES)130/0.4/6%, and to determine the relationship between RRT indication and mortality.

Methods We studied 165 consecutive patients admitted to the critical care burn unit. Resuscitation was performed using lactated Ringer’s solution and HES at a low dose to achieve urine output, lactate levels, and transpulmonary thermomodulation parameters. The contributions of colloids and crystalloids were measured, and renal function was evaluated. Statistical analysis was performed using the Spearman test.

Results The average total body surface area (TBSA) burned was 30 ± 15%, and the median of the total volume needed in the first 24 hours was 4.01 ml/kg% TBSA burned. According to the RIFLE criteria, 10 (6.1%) patients presented with risk, 11 (6.7%) presented with injury, and 11 (6.7%) presented with failure. According to the AKIN criteria: 9.7% presented stage 1, 3% stage II and 10.3% stage III. Replacement therapy (RRT) was performed in 15 patients (9.1%). In six of these patients RRT was employed in the final stages of multiorgan failure. In the remaining nine patients, for various reasons only one survived.

Conclusion During the resuscitation phase of the burn patients, the use of HES (130/0.4/6%) at low doses does not seem to cause more risk or injury according to RIFLE or AKIN criteria than those reported by studies in burn patients resuscitated without HES. However, the need for RRT is associated with a high mortality, although in many cases the display is terminal.

Influence of anaesthetic factors on skin graft viability in a burns ICU
C Isitt, KA McCloskey, A Cabello, P Sharma, MP Vizcaychipi Chelsea and Westminster Hospital, London, UK

Introduction Graft failure is a major cause of morbidity in patients with burns, resulting in increased length of hospital stay and increased number of operations. At our regional burns unit we collated the data from anaesthetic charts of patients admitted to our burns ICU who required skin grafting. The aim was to analyse whether any anaesthetic variables contribute to graft failure.

Methods Thirty-five patients were included in the analysis with a total of 191 operations. These were a combination of debridement, split skin grafts (SSG) and change of dressings. All patients were admitted to our burns ICU between January 2009 and October 2013. Exclusion criteria were death prior to discharge and initial surgery at a different hospital. Sixteen patients had good graft viability (Group A) and 19 patients had poor graft viability (Group B). Logistical regression was performed using SPSS (Version 22.0). Hosmer and Lemeshow testing was used to confirm goodness of fit. Independent variables were age, sex, preoperative haemoglobin, intraoperative fluid resuscitation, blood products, inotropes, volatile agents and temperature. Poor graft viability was defined as requiring at least one additional skin graft. Analysis was performed on all operations and then by subtype of operation (that is, SSG and debridement, SSG only).
Results There was no significant difference in age, total burn surface area or Belgian Outcome Burns Injury score between the groups. For all operation data, use of colloids was found to significantly contribute towards poor graft viability (P = 0.039, 95% CI). When analysis was performed on only SSG and debridement operations, colloids remained significant (P = 0.034, 95% CI) and metarminol use was found to significantly contribute (P = 0.028, 95% CI) to poor graft viability. Overall use of inotropes was not significant between the two groups. Other variables including minimum and maximum temperature, preoperative haemoglobin and blood transfusion were not found to be significant.

Conclusion Our results suggest that the use of colloids is a contributor to poor graft viability in burns. This was found to be independent of temperature and overall inotrope use; however, the use of metarminol may be a contributing factor.

Association of elevated levels of plasma chloride, in severity and mortality, in adult patients in the ICU
M Aguilar Arzapalo
Hospital O’Horan, Mérida, Mexico

Introduction For a long time, many investigators have tried to demonstrate increased mortality associated with acid–base disturbances. In this study, we sought to determine the association of hyperchloremia measured at ICU admission and whether this electrolyte disturbance is associated with an increase in morbidity and mortality.

Methods Data were retrospectively collected for consecutive adult patients admitted to Agustin O’Horan Hospital ICU, between January 2011 and July 2014, who underwent inpatient medical treatment using electronic files.

Results The dataset consisted of 936 medical files and serum chloride concentration values on admission, 853 being eligible. Hyperchloremia (serum chloride >110 mmol/l) is quite common, with an incidence of 47.71%. Patients were propensity matched based on their association with death and hyperchloremia. Of the 853 patients collected, patients with hyperchloremia after admission (n = 446, 52.3%), patients were matched to patients who had normal serum chloride levels after admission. These two groups were well balanced with respect to all variables collected. The hyperchloremic group was at increased risk of mortality at ICU discharge, relative risk ratio = 1.81; 95% confidence interval, 1.41 to 2.51 risk increase of 25.31%. Admission hyperchloremia was associated with increased morbidity, mortality and higher scores in severity scales; this association was statistically important. See Figure 1.

Conclusion This retrospective cohort trial demonstrates an association between hyperchloremia and poor ICU admission outcome (death). Additional studies are required to demonstrate a causal relationship between these variables.

Urinary strong ion difference and acute kidney injury: an early marker of renal dysfunction?
P Balsorano1, A De Gaudio1, Stefano Romagnoli1, Ipsita Krishnan2
1AOU Careggi, Florence, Italy; 2Rhode Island Hospital, Providence, RI, USA

Introduction Kidneys play a crucial role in the regulation of electrolytes and acid–base homeostasis. Impaired renal function is associated with greater urinary strong ion difference (SIDu) in patients with metabolic acidosis. In critically ill patients, several factors, such as infused fluids and acid endogenous production, would lead to changes in plasma SID and acid–base homeostasis without renal regulation of urinary electrolytes and SIDu [2]. Hence, AKI can be highlighted as an inability to address acid–base metabolic disturbances, which may be detected before major increases in creatinine or decreases in urine output. We evaluated the effects of renal function on urinary strong ion excretion using the Stewart approach to acid–base in critically ill patients with AKI.

Methods A retrospective study was conducted. Patients with a diagnosis of AKI according to KDIGO creatinine criteria and available urinary chemistry at one point during their ICU stay were evaluated. Day 0 was defined as the day when SIDu was calculated from urinary spot analysis (SIDu = Na+U + K+U – Cl–U). Patients were followed and staged for AKI in the next 3 days. AKI reversibility was defined according to the lack of criteria for AKI.

Results In total, 143 critically ill patients with a diagnosis of AKI were included. SIDu at day 0 did not differ between different AKI stages at day 0. SIDu at day 0 was statistically different between different AKI stages at days 1, 2, 3 (Table 1). SIDu at day 0 was statistically different between reversible and non-reversible AKI at days 1, 2, 3 (Table 2). A conventional receiver-operating curve was generated to assess the accuracy of SIDu to predict AKI reversibility at day 1. AUC for SIDu was 0.82 (P < 0.0001; 95% CI: 0.75 to 0.88).

Conclusion SIDu identified patients with reversible AKI with good accuracy. SIDu can be a promising, simple and cost-effective tool in AKI patient evaluation. Further research is needed to assess SIDu capability to early detect patients with renal dysfunction before increases in creatinine or decreases in urine output.

Evaluation of the effect of guidelines to reduce intravenous potassium infusions in ICU patients
MC Law Min¹, RS Bournel¹, S Burd², M Stone²
¹Sheffield Teaching Hospitals, Sheffield, UK; ²De Montfort University, Leicester, UK

Introduction The aim was to evaluate whether guidelines for intravenous (i.v.) potassium replacement improved plasma potassium homeostasis in ICU patients. Prompt and effective treatment of hypokalaemia is an important intervention in the ICU, but concentrated i.v. potassium solutions may cause serious harm if used inappropriately [1]. There were previously no formalised guidelines on i.v. potassium supplementation in the ICU at Sheffield Teaching Hospitals. Practice was reviewed and guidelines were introduced to improve patient safety, plasma potassium homeostasis and reduce i.v. potassium supplementation requirements.

Methods A before and after evaluation of plasma potassium homeostasis in ICU patients requiring i.v. potassium supplementation was conducted over a period of 8 months (August 2013 to May 2014). Patient data on plasma potassium levels, i.v. and oral potassium supplements administered were obtained from the clinical information system. Clinical appropriateness of i.v. potassium acetate prescriptions, fluid and chloride intake related to potassium infusions and cost linked to the guidelines were also compared pre/post implementation. Impact of the guidelines on nurses’ practice was assessed using questionnaires.

Results Median i.v. potassium replacement dose per patient was significantly reduced in the post-guidelines group from 215 (IQR: 94; 485) to 80 (IQR: 40; 160) mmol; P < 0.001. Although the percentage time per group for patients who were hypokalaemic was less in the post group (18.2% vs. 14.8%), there was no difference in mean patient values (24.2 (20.3)% vs. 22.1 (17.5)%; P = 0.228). The duration of hyperkalaemia was increased. Prescribing of i.v. potassium acetate was not always appropriate. Median patient fluid-related dose was increased (107.5 (IQR: 47.1; 242.4) vs. 250 (IQR: 100; 600) ml; P < 0.001), whilst chloride doses were reduced (170.7 (IQR: 91.3; 438.3) vs. 110 (IQR: 55; 250) mmol; P < 0.009). Nurses were satisfied with the new practice, reporting it was safe, effective and clinically useful. However, compared with baseline practice, they perceived the guidelines as less effective and felt the workload was higher.

Conclusion Implementation of i.v. potassium replacement guidelines improved the use of i.v. potassium in the ICU by reducing the requirement for i.v. potassium supplementation and increasing the overall time patients spent without hypokalaemia. Whilst nursing staff found the guideline useful and felt it increased safe use of i.v. potassium, more work is needed to ensure nurse workload is not increased significantly.

Marked exposure to the endocrine-disrupting chemicals phthalates and bisphenol A in the ICU
J Huysgh, P Jorens
Antwerp University Hospital, Edegem, Belgium

Introduction Care for ICU patients has benefited from medical devices. Bisphenol A (BPA) and phthalates can leach from the plastic matrix. They are endocrine-disrupting chemicals (EDCs) and may be associated with endocrine-related morbidity and mortality. The aim was to evaluate whether guidelines for intra-venous (i.v.) potassium replacement improved plasma potassium homeostasis in ICU patients. Prompt and effective treatment of hypokalaemia is an important intervention in the ICU, but concentrated i.v. potassium solutions may cause serious harm if used inappropriately [1]. There were previously no formalised guidelines on i.v. potassium supplementation in the ICU at Sheffield Teaching Hospitals. Practice was reviewed and guidelines were introduced to improve patient safety, plasma potassium homeostasis and reduce i.v. potassium supplementation requirements.

Methods A before and after evaluation of plasma potassium homeostasis in ICU patients requiring i.v. potassium supplementation was conducted over a period of 8 months (August 2013 to May 2014). Patient data on plasma potassium levels, i.v. and oral potassium supplements administered were obtained from the clinical information system. Clinical appropriateness of i.v. potassium acetate prescriptions, fluid and chloride intake related to potassium infusions and cost linked to the guidelines were also compared pre/post implementation. Impact of the guidelines on nurses’ practice was assessed using questionnaires.

Results Median i.v. potassium replacement dose per patient was significantly reduced in the post-guidelines group from 215 (IQR: 94; 485) to 80 (IQR: 40; 160) mmol; P < 0.001. Although the percentage time per group for patients who were hypokalaemic was less in the post group (18.2% vs. 14.8%), there was no difference in mean patient values (24.2 (20.3)% vs. 22.1 (17.5)%; P = 0.228). The duration of hyperkalaemia was increased. Prescribing of i.v. potassium acetate was not always appropriate. Median patient fluid-related dose was increased (107.5 (IQR: 47.1; 242.4) vs. 250 (IQR: 100; 600) ml; P < 0.001), whilst chloride doses were reduced (170.7 (IQR: 91.3; 438.3) vs. 110 (IQR: 55; 250) mmol; P < 0.009). Nurses were satisfied with the new practice, reporting it was safe, effective and clinically useful. However, compared with baseline practice, they perceived the guidelines as less effective and felt the workload was higher.

Conclusion Implementation of i.v. potassium replacement guidelines improved the use of i.v. potassium in the ICU by reducing the requirement for i.v. potassium supplementation and increasing the overall time patients spent without hypokalaemia. Whilst nursing staff found the guideline useful and felt it increased safe use of i.v. potassium, more work is needed to ensure nurse workload is not increased significantly.

Low serum 25-hydroxyvitamin D at critical care initiation is associated with sepsis and morbidity in Dutch critically ill patients
K De Haan
Erasmus MC, Rotterdam, the Netherlands

Introduction Vitamin D deficiency may frequently occur in critically ill patients and may be associated with sepsis and increased mortality. We therefore evaluated the prevalence of 25-hydroxyvitamin D deficiency in a Dutch ICU, and its relationship with sepsis, morbidity and mortality.

Methods We conducted a prospective observational study in a 10-bed mixed ICU. A total of 1,372 patients were admitted between July 2011 and June 2013 including 198 readmissions, of which 940 patients were studied. 25-Hydroxyvitamin D levels were determined within 24 hours after admission. 25-Hydroxyvitamin D levels were judged as sufficiency (>50 nmol/l), insufficiency (30 to 50 nmol/l) and deficiency (<30 nmol/l).

Results The prevalence of deficiency and insufficiency was 36% and 38%, respectively. Only 26% of the patients had sufficient vitamin D levels. Vitamin D deficiency is associated with sepsis (P < 0.001) at ICU admission. Patients with deficient levels had higher mean APACHE IV scores, 64 versus 52 (P < 0.001), and longer length of hospital stay, 12 versus 9 days (P < 0.001), respectively, as compared with patients with sufficient levels. Patients with deficient vitamin D levels had an odds ratio for in-hospital mortality of 1.4 (95% confidence interval of 0.84 to 2.29, P = 0.2) relative to patients with sufficient vitamin D levels.

Conclusion 25-Hydroxyvitamin D deficiency frequently occurs in Dutch critically ill patients. Although relating to sepsis, disease severity and morbidity, vitamin D deficiency is not an independent predictor of mortality in these patients, which was otherwise relatively low.
6 to 9 months post ICU admission to screen for disturbed glucose metabolism. Furthermore, we examined whether post-discharge glucose disturbances could be predicted by the FINDRISC questionnaire [2], patient demographics, comorbidities, HbaA1c at ICU admission, and by parameters related to ICU stay (glucose parameters, insulin need, caloric intake, disease severity).

Results In total, 246 patients (73%) experienced SH during their ICU stay. Eight months post ICU admission, glucose metabolism was disturbed in 119 (35%) subjects. Of these, 27 (8%) had impaired fasting glucose, 43 (13%) had impaired glucose tolerance, 25 (7%) had impaired fasting glucose and impaired glucose tolerance, and 24 (7%) were diagnosed with DM. A disturbed glucose metabolism tended to be more prevalent in subjects who experienced SH during ICU stay as compared with those without SH (38% vs. 28%, P = 0.065). HbaA1c on admission correlated with the degree of SH (r = 0.308, P < 0.001). The FINDRISC score (r = 0.15, P = 0.001). SAPS 3 score (median of 42 in both groups, P = 0.003) and daily caloric intake during ICU stay (222 vs. 197, P = 0.011) were associated with a DGM.

Conclusion Stress hyperglycaemia is frequent in nondiabetic patients and has a tendency towards future disturbances in glucose metabolism and DM. Glucose metabolism was disturbed in 35% of subjects 8 months post-ICU admission, of whom 7% was diagnosed with diabetes mellitus. Predictors of elevated risk included a high FINDRISC score, high SAPS 3 score, and daily caloric intake during ICU stay.

Associations between the degree of correction of hypoglycemia and ICU mortality
R Van Hooijdonk1, JM Binnekade1, A Abu-Hanna1, F Van Braam Houckgeest2, LS Hofstot1, J Horn1, MA Kuiper1, NP Juffermans1, HL Van den Oever3, JP Van der Sluijs1, PE Spronk1, MJ Schultz1
1Academic Medical Center, Amsterdam, the Netherlands; 2Tergooi Hospitals, Hilversum, the Netherlands; 3Scherper Hospital, Emmen, the Netherlands; 4Medical Centre Leeuwarden, the Netherlands; 5Deventer Hospital, Deventer, the Netherlands; 6Medical Center Haaglanden, The Hague, the Netherlands; 7SumStats Ltd, Edinburgh, UK; 8CARE Hospitals, Hyderabad, India; 9GlySure Ltd, Abingdon, UK

Introduction It is conjectured that transition of hypoglycemia to hyperglycemia may be more harmful than hypoglycemia itself. We investigated the association between the degree of correction of hypoglycemia and ICU mortality in patients under moderately strict to strict glycemic control.

Methods This is a retrospective analysis from a pooled cohort from seven ICUs in the Netherlands over 6 years. ICU patients who developed hypoglycemia (<70 mg/dl) were included. We excluded patients who were readmitted, and patients with hypoglycemia in whom no follow-up blood glucose measurement was performed within 8 hours. We determined the association between three measures of correction of hypoglycemia within 8 hours after hypoglycemia and ICU mortality: predefined ranges of the ‘highest blood glucose level’ (<80 mg/dl; 80 to 110 mg/dl; 110 to 150 mg/dl; 150 to 180 mg/dl; and >180 mg/dl) quartiles of the ‘delta glucose’, defined as the difference between minimum and maximum blood glucose level with the third quartile as reference category; and quartiles of the ‘standard deviation’ of the blood glucose level with the third quartile as reference category.

Results In total, 4,516 ICU patients developed at least one episode of hypoglycemia. In three separate multivariate analyses for each of the three measures we adjusted for the respective confounders. The category 80 to 110 mg/dl of the ‘highest blood glucose level’ was associated with increased mortality compared with the reference category (odds ratio (OR) = 1.31, 95% confidence interval (CI) = 1.06 to 1.61). The lowest quartile of the ‘delta glucose’ (OR = 1.32, 95% CI = 1.03 to 1.69) and the lowest quartile of the ‘standard deviation’ (OR = 1.55, 95% CI = 1.23 to 1.96) were associated with higher ICU mortality than their reference categories.

Conclusion Not the transition to hyperglycemia, but insufficient recovery from hypoglycemia is associated with an increased ICU mortality in patients under moderately strict or strict glucose control with insulin.
glucose data prove in such routine use? Using actual case data, we have shown how comparing the mean absolute relative difference (MARD) and integration of the area under the curve (AUC) from the continuous glucose monitoring and intermittent measurement can be used to measure patient risk.

Methods The analysis used aggregated case data generated from our recent clinical trials, where a GlySure sterile, single-use sensor and dedicated monitoring system was used to measure the blood glucose concentration in patients continuously and in real time. The measurement of risk was compared using the MARD, an accepted error calculation tool, and the AUC was calculated using an AUC analysis software program.

Results When MARD from the GlySure sensor and intermittent measurement using the hospital’s existing protocol was compared, the measure of risk to the patient (that is, the uncertainty regarding the patient’s absolute blood glucose status) for the GlySure sensor was 50.5% lower than the intermittent measurement. The results also showed that as the variability of the BG data increases, the benefit of continuous monitoring increases by significantly reducing patient risk. The continuous monitoring reduces the patient’s risk by 88%, 73%, and 69% respectively in high, medium and low variability situations.

Conclusion It is more and more evident that continuous glucose technology will be instrumental in driving safe and effective glucose management protocols that will support more consistent glycemic management standards within ICUs and across institutions.

P371 Effect of admission hyperglycemia in sepsis patients with or without a history of diabetes
LA Van Vught1, MA Wiewel1, PM Klein Klouwenberg2, AJ Hoogendijk1, DS Gong1, OL Cremer1, MJ Bonten1, MJ Schultz1, T Van der Pol1
1Academic Medical Center, Amsterdam, the Netherlands; 2University Medical Center Utrecht, the Netherlands

Introduction Hyperglycemia is common and often multifactorial in critically ill patients. The association of hyperglycemia with adverse outcome has repeatedly been established in a variety of settings. The objective of this study was to investigate whether hyperglycemia on admission to the ICU impacts presentation and outcome of sepsis patients antemural this effect is different for patients with a history of diabetes mellitus.

Methods A two-center, prospective observational cohort study was conducted including all consecutive critically ill patients admitted to the ICU between January 2011 and July 2013. Sepsis patients were identified using strict clinical and diagnostic criteria. The first glucose measurement within a time window of 4 hours before up to 4 hours after ICU admission was categorized into euglycemia (71 to 140 mg/dl), mild hyperglycemia (141 to 200 mg/dl) or severe hyperglycemia (>200 mg/dl), patients with hypoglycemia were excluded. A multivariable Cox proportional hazard model was used to determine the effect of admission hyperglycemia on mortality corrected for covariates.

Results Of the 1,059 patients admitted with sepsis, 526 (55.8%) had admission glucose levels within the normal range, 270 (25.5%) had mild hyperglycemia and 202 (19.1%) severe hyperglycemia. Patients with severe hyperglycemia were older, had higher APACHE IV scores and were more often diabetics compared with euglycemic patients. Shock on admission was more common in patients admitted with euglycemia. Crude mortality increased with increased admission glucose and a Cox regression analysis showed increased risk for 30-day (HR = 1.67, CI = 1.24 to 2.23), 60-day (HR = 1.42, CI = 1.08 to 1.87) and 90-day (1.31, CI = 1.02 to 1.70) mortality in patients admitted with severe hyperglycemia compared with euglycemia. The association between mortality and severe hyperglycemia on admission was only present in patients without known diabetes but not in patients with a history of diabetes (30-day mortality HR = 1.67, CI = 1.15 to 2.43 vs. 1.84, CI = 0.97 to 3.49). Severe hyperglycemia was associated with a blunted proinflammatory cytokine response (IL-6 and IL-8) on admission in patients without, but not in patients with diabetes.

Conclusion Severe hyperglycemia on admission is associated with increased 30-day, 60-day and 90-day mortality in sepsis patients without a history of diabetes mellitus.

Acknowledgement This research was performed within the framework of the Center for Translational Molecular Medicine (http://www.ctmm.nl), project MARS (grant 041-201).
microdialysis-based continuous glucose monitoring (CGM) (EIRUS®; Maquet Critical Care AB, Solna, Sweden).

**Methods** Patients with an expected stay in the ICU of >48 hours needing an arterial catheter and a central venous catheter (CVC) were eligible. For a maximum of 3 days, during 8 hours per day, 1.25 μl blood was drawn from the arterial line every 15 minutes. Point accuracy was expressed using Clarke error grids, Bland–Altman plots and glucose prediction error analysis [4,5]. Trend accuracy was expressed using continuous glucose error grid analysis [6].

**Results** Three-hundred and fifty-four paired samples were obtained from seven patients (66 (59 to 79) years old, APACHE II score 23 (20 to 28), 51 (19 to 77) samples per patient). Point accuracy: 91% of paired values were in zone A, with the remaining 9% of the values in zone B in the Clarke error grid. In the Bland–Altman, bias was 5.4 mg/dl with an upper limit of agreement of 32.5 mg/dl and a lower level of agreement of –21.8 mg/dl. Glucose prediction error analysis showed that 91% of the values ≤75 mg/dl within 20% of the values measured by the blood gas analyzer were within range. Trend accuracy: in the rate error grid of the continuous glucose error grid analysis, 96% of the paired values were in zone A, 3.7% were in zone B and 0.3% were in zone C.

**Conclusion** Point and trend accuracy of the tested microdialysis-based CGM are good in critically ill patients.

Acknowledgment: This two-center randomized controlled study of glucose control provided two CGM systems and disposables for the duration of the study, but had no influence on study design or study reporting.

Methods In this single-centre observational study we prospectively enrolled all patients undergoing elective cardiac surgery. The primary output was the time to faeces (TTFE) as representing the postoperative ileus. Secondary outputs were the occurrence of ischaemic colitis and pneumonia. Quantitative variables were compared by ANOVA or Wilcoxon tests, qualitative variables by chi-square tests. Multivariate analyses were performed by logistic regression, \( P < 0.1 \) for inputs \( P < 0.05 \) for outputs.

Results We included 349 patients: age 67.5 ± 10.8 years, M/F sex ratio 252/97, preoperative left ventricle ejection fraction 58.8 ± 10.6%, bypass valve ratio 234/154, number of grafts 2.7 ± 0.9, mammal arteries 1.8 ± 0.5. In univariate analyses, bypasses received more anaesthetic drugs \( (P < 0.01) \), had shorter extracorporeal circulation duration, 67 ± 27 versus 75 ± 24 minutes \( (P < 0.01) \), and received less blood products \( (P < 0.0001) \). Bypasses had lower postoperative levels of troponin \( (3.9 ± 7.6 \text{ vs. } 8.1 ± 21 \text{ pg/ml}, P < 0.01) \) and LDH \( (330 ± 162 \text{ vs. } 420 ± 175 \text{ pg/}

ICU outcome of patients undergoing cytoreductive surgery followed by hyperthermic intraperitoneal chemotherapy: a single-center study

A Nadeem, A Al-Tarifi

King Faisal Specialist Hospital, Riyadh, Saudi Arabia

Introduction Peritoneal carcinomatosis (PC) is associated with poor prognosis. The advent of complete cytoreductive surgery (CRS) followed by hyperthermic intraperitoneal chemotherapy (HIPEC) has shown promise in improved survival for locally advanced intra-abdominal carcinomatosis. Such patients are routinely admitted to the ICU postoperatively. Little is known about the natural course of such patients while in the ICU.

Methods The procedure CRS/HiPEC was introduced in our hospital in 2008 as the first regional center performing such therapy. A retrospective chart review of 129 cases of CRS-HIPEC admitted to a 22-bed surgical ICU in a tertiary care academic center between November 2008 and March 2014. Primary outcomes were ICU length of stay (LOS) and duration of mechanical ventilation (MV). Secondary outcomes were hospital LOS and hospital mortality.

Results Eighty-seven patients (69.9%) were females. Mean age was 48.9 years. Primary cancer was colorectal in 42 patients (32.5%), ovarian in 39 (30%), appendiceal in 29 (22%), others in 15.5%. Average operative time was 11 ± 2.1 hours. Average intraoperative crystalloids given were 12,217 ± 4,359 ml, packed RBCs were 2 ± 2.3 units, colloids 1,083 ± 898 ml, average blood loss was 1,108 ± 785 ml. All patients were admitted to the ICU post procedure. The average fluid balance during the OR was 9,481 ± 4,694 ml. Patients stayed in the ICU for an average of 6 ± 5.3 days. All patients survived the ICU stay. The duration of mechanical ventilation was 57 ± 83 hours, total fluid balance while in the ICU was 1,147 ± 3,399 ml. Hypomagnesemia was the most frequent electrolyte abnormalities in 79 (61%). Pleural effusions in 48 (37%), of which three patients only required drainage, Seven patients (5.6%) developed pneumonia, no patient required renal replacement therapy. Average hospital LOS was 33.7 ± 29 days. Only two patients died in the hospital. When the first 65 patients were compared with the last 64 patients, the duration of MV, ICU LOS and hospital LOS were all significantly shorter in the latter group (72 vs. 43 hours, 6.8 vs. 5.0 and 40 vs. 27 days respectively; \( P < 0.01 \) for all).

Conclusion With proper selection of patients, CRS with HIPEC can be done safely with no major complications. There is a significant reduction in ICU utilization and shorter hospital LOS with more experience in such procedure, suggesting a learning curve as well as better utilization of resources by referring such patients to a high-volume center.
P378
Warm ischemia time, postperfusion syndrome and initial poor function after liver transplantation: are they connected?
E Scarlat, T Mang, G Droc, D Tomescu
Fundeni Clinical Institute, Bucharest, Romania

Introduction Factors associated with initial poor graft function (IPGF) after liver transplantation are still under debate. Although the initial insult to the graft begins during the cold ischemia time (CIT), recent studies showed that most injuries occur during rewarming. Ischemic–reperfusion (I/R) injuries are present in all grafts and may be responsible for postoperative graft dysfunction. Along with other factors, I/R injury may also play a role in the development of postperfusion syndrome (PRS) after revascularization of the liver graft. The aim of this study was to assess whether longer warm ischemia time (WIT) is associated with PRS or with IPGF after liver transplant. The secondary aim was to investigate whether patients with intraoperative PRS have a higher risk for postoperative IPGF.

Methods This retrospective observational study included 60 liver transplant patients. We excluded from the study group patients with retransplant procedures, and the recipients of divided grafts and of grafts from HBsAg and anti-HIV donors. We recorded: demographic data, intraoperative PRS, CIT, WIT, ALT, AST levels and standard coagulation tests on postoperative days (POD) 1 to 5. Statistical analysis was performed using SPSS Statistics v.19.1 with significant P-value under 0.05.

Results We used the criteria of Nanashima and colleagues for the diagnosis of IPGF (ALT and/or AST level above 1,500 IU/l within 72 hours after OLT). The study group included 33 men (55%) and 27 women. Mean (±SD) age was 50.56 (±13.26) years. WIT longer than 60 minutes correlated significantly with ALT and AST levels in POD 1 to 3 (P < 0.0001 for ALT in POD 1 to 3, P = 0.001 for AST in POD 1, P = 0.007 and 0.013 for AST in POD 2 and 3) and with prothrombin time (P = 0.008 in POD 1, P = 0.03 in POD 2 and P = 0.015 in POD 3). We could not find a correlation between PRS and WIT (P = 0.566), CIT (P = 0.439) or transaminase levels on POD 1 to 3. The correlation between WIT > 60 minutes and IPGF was confirmed using the Pearson chi-square test (P < 0.0001). The same test was used to correlate IPGF with PRS with nonsignificant results (P = 0.876).

Conclusion Our study showed that PRS is not a risk factor for IPGF after liver transplantation. WIT over 60 minutes does not influence the development of PRS, but is associated with IPGF after liver transplantation. Close monitoring of liver tests in the early postoperative period is very important especially in recipients of grafts with WIT over 60 minutes. Further efforts to decrease WIT may prove useful for the reduction of IPGF in liver transplant patients.

P379
Seroprevalence of hepatitis B, hepatitis C and HIV in ICU patients
H Bayr, I Yildiz, E Kocoglu, A Kurt, H Kocoglu
Abant Izzet Baysal University, Medical School, Bolu, Turkey

Introduction Healthcare workers are at risk for infections caused by hepatitis B (HBV), hepatitis C (HCV) and human immunodeficiency (HIV) viruses that transmit via blood and body fluids. In the present study, it was aimed to investigate the seroprevalences of HBsAg, anti-HCV and anti-HIV in healthcare workers in our hospital. We recorded: demographic data, anti-HCV and anti-HIV tests results and demographical data of the patients admitted to the Reanimation ICU between January 2012 and December 2014 were evaluated retrospectively. HBsAg, anti-HCV and anti-HIV tests were assayed with a macro-ELISA method (Axysym-Abbot, Architect i2000; Abbott, USA). Statistical analysis was performed with the chi-square test.

Results The sample comprised 600 healthcare workers. For HBsAg, anti-HCV and anti-HIV tests results and demographical data of the patients admitted to the Reanimation ICU between January 2012 and December 2014 were evaluated retrospectively. HBsAg, anti-HCV and anti-HIV tests were assayed with a macro-ELISA method (Axysym-Abbot, Architect i2000; Abbott, USA). Statistical analysis was performed with the chi-square test.

Conclusion In the present study, it was observed that the seroprevalences of HBsAg, anti-HCV and anti-HIV were not higher than in our city population. However, taking the safety precautions of the healthcare workers during surgical or invasive procedures such as catherization, intubation or tracheostomy without any information about the serological test results of the patients will reduce the contamination of these agents.

Outcomes of decompensated chronic liver disease in a UK district general hospital critical care setting
E Ahmadinia, F Mannehvi, R Raveendran
Homerton University Hospital, London, UK; Queen’s Hospital, London, UK

Introduction Patients with decompensated cirrhosis admitted to the ICU have historically had a very high mortality rate [1]. It has been suggested that improving patient selection can improve ICU outcomes in patients with cirrhosis [2]. The aim of this study was to determine the mortality and evaluate the risk factors that may influence the outcome of this group of patients in a large UK district general hospital with a view to introducing selection criteria for future ICU admission of patients with decompensated liver disease.

Methods A retrospective analysis was performed of all adult patients with decompensated chronic liver disease admitted to a general (nontransplant) critical care unit between January 2012 and December 2013. Data were collected regarding demographics, ICU mortality, hospital mortality, aetiology of chronic liver disease, severity scores, acute diagnoses, and organ support requirements.

Results Thirty-seven patients were identified, with a median age of 57 years, predominantly male (62%). Seventy-six per cent had alcohol-related cirrhosis. Overall ICU mortality was 29.7% and hospital mortality was 48.6% – these values were higher in the alcoholic group (39.3% and 57.1% respectively). All ICU deaths were in those with alcoholic liver disease. Median scores were: APACHE III 93, SOFA (day 1) 9, Child–Pugh 11, MELD 21. Seventy per cent were treated for sepsis, 22% had a Gl bleed, 57% had encephalopathy, 24% had suspected/confirmed spontaneous bacterial peritonitis, and 70% had an acute kidney injury. Organ support requirements were: 35% respiratory (non-invasive or invasive ventilation), 38% vasoactive agent support, 24% renal replacement therapy (RRT). Alcoholic liver disease patients requiring respiratory or cardiovascular support had an ICU mortality of 64%, and those requiring RRT had a mortality of 75%. Alcoholic liver disease patients requiring combined respiratory, cardiovascular, and RRT support had 100% mortality. Conclusion Those with decompensated chronic liver disease admitted to the ICU have a significant ICU/hospital mortality, which is increased in alcoholic liver disease. Sepsis and AKI were the most common acute diagnoses in this cohort. Alcoholic liver disease patients requiring organ support have a very high mortality, and the outlook for multiorgan failure requiring RRT in this group is dismal.

Prometheus® liver therapy in children with acute liver failure
Ghent University Hospital, Gent, Belgium

Introduction The Fractionated Plasma Separation and Adsorption System Prometheus® (Fresenius Medical Care, Germany) aims at being
a supportive therapy as a bridge to transplantation or recovery in adults with liver failure. The system offers specific challenges when applied in children due to the large extracorporeal volume (700 to 750 ml). We therefore developed an adapted protocol for the application in children.

**Methods** Priming of the blood circuit is performed using 2 l isotonic saline, whereas the plasma circuit, containing both adsorption devices, is filled with 2 l fresh frozen plasma or 400 ml stabilized solution of human plasma proteins. Next, for children with body weight (BW) <25 kg, a solution of 60 to 65% packed cells (PC) is infused in the inlet blood line at 40 ml/minute. The volume of PC needed is calculated based on the circuit priming volume and the maximum allowed extracorporeal blood volume of the child (=8 ml/kg x BW). After the priming phase, blood and plasma flow are increased to at least 100 ml/ minute and 200 ml/minute respectively, and dialysate flow is set at 300 ml/minute. Regional citrate anticoagulation is done with a calcium-free dialysate, while, eventually, heparin is added to the priming solution.

Post treatment, the circuit volume is either not reinflated (BW <25 kg) or reinflated using isotonic saline (BW >25 kg), with a volume depending on the hydration status and the originally infused volume of PC. Reduction ratios (RRs, %) of urea, creatinine (Crea), bilirubin (bili), and ammonia (NH3) were calculated from pretreatment and posttreatment serum concentrations. Primary and secondary patient outcome was 33 (intervarial range 26 to 39), with an uncuffed double lumen dialysis catheter (8 to 14 Fr Femoralis (n=6) and 9 Fr Jugularis (n=2)) were treated according to this protocol. In total, 19 sessions were executed using FX40 (n=13), FX50 (n=3), and FX60 (n=3) dialysers during 6.5 ± 0.9 hours. Blood flow was 149 ± 45 ml/minute, albumin flow 226 ± 49 ml/minute, and ultrafiltration flow 432 ± 517 ml. RRs were 70 ± 15% (urea), 34 ± 14% (Crea), 44 ± 16% (bili), and 36 ± 10% (NH3). Primary survival rate was 100%. Four patients were transplanted (bridge to transplant) of which, however, one died within 30 days after discharge from the ICU. The fifth patient died due to primary disease 9 months after treatment, and the remaining three patients fully recovered (bridge to recovery).

**Conclusion** This adapted Prometheus® protocol is promising for the treatment of children with liver failure.

**Molecular adsorbent recirculating system treatment in 69 patients listed for liver transplantation**

P Olin, H Haugaa

Oslo University Hospital, Oslo, Norway

**Introduction** The molecular adsorbent recirculating system (MARS) is used to remove circulating albumin-bound toxins in patients with liver failure. However, the application of MARS has not demonstrated improved survival in randomized clinical trials and the clinical utility has not been finally established. In our department, the use of MARS is now restricted to the most critically ill patients with acute or acute on chronic liver failure. We aimed to explore MARS efficacy in removing toxicity parameters and the safety of the system.

**Methods** Since 2005, we have treated 69 patients (30 males/39 females with median age of 39 years ranging from 1 month to 70 years) listed for liver transplantation with MARS. The median Model of End Stage Liver Disease (MELD) score in patients older than 12 years of age (n = 56) was 33 (interquartile range 26 to 39). The flow rate was 35 to 40 ml/kg/hour and treatment kits were changed every 8 to 12 hours. The patients were treated for a median of 31 hours (range 1 to 240 hours).

**Results** Fifty-five patients (79%) were successfully bridged to transplantation. Nine died before they could be transplanted, and five patients recovered without liver transplantation. Forty-four (81%) of the transplanted patients were alive 30 days after transplantation. Ammonium decreased modestly from a median of 148 to 124 µM (P = 0.03) during MARS treatment. We detected worsening of coagulopathy with significant decreases in platelet count and fibrinogen concentrations, and increase in International Normalized Ratio. Phosphate and magnesium decreased significantly during MARS treatment.

**Conclusion** Close observation and treatment of coagulopathy and electrolyte disturbances is essential when treating patients with MARS. MARS can reduce and stabilize ammonium and other biomedical markers in patients listed for urgent liver transplantation with high MELD score and liver encephalopathy. It seems that, in some cases and with our settings, the detoxification properties of MARS may be insufficient.

**First clinical experience with a new type of albumin dialysis: the HepaWash® system**

B Henschel, R Schmid, W Huber

TU-München Klinikum rechts der Isar, Munich, Germany

**Introduction** Liver failure (LF) is associated with prolonged hospital stay, increased cost and substantial mortality. With regard to a limited number of donor organs, extracorporeal liver support is an appealing concept to bridge to transplant or to avoid transplant in case of recovery. A new type of albumin dialysis, the HepaWash® system, was recently introduced. The HepaWash® system provides rapid regeneration of toxin-binding albumin by secondary circuits altering binding capacities of albumin by biochemical (changing pH) and physical (changing temperature) modulation of the dialysate.

**Methods** We evaluated the first 14 patients treated with the HepaWash® system with regard to safety and efficacy. Seven patients were treated in the context of the run-in phase of the studies (HEPATICUS 1 and HEPATICUS 2) and seven patients were treated since the HepaWash® system received the CE certificate in July 2013. Patients treated suffered under acute on chronic LF (n = 9) or secondary LF which resulted from nonhepatic diseases such as sepsis (n = 5). Primary endpoint: comparison of serum bilirubin, creatinine and serum BUN before and after the first treatment with the HepaWash® system. Statistics: IBM SPSS Statistics version 22. The Wilcoxon test for paired samples was used to detect significant treatment effects.

**Results** A total of 254 treatments (1 to 101 per patient) were performed in 14 patients (six female, eight male). Mean age 54 ± 13. MELD score 33.7 ± 7.0, CLIF-SOFA 14.6 ± 2.7. Main underlying disease: nine acute-on-chronic LF; five secondary LF. While bilirubin did not change significantly on the day before HepaWash® treatment (26.2 ± 15.4 vs. 26.0 ± 15.4 mg/dl; P = 0.116), serum bilirubin levels were significantly decreased by the HepaWash® procedure (26.0 ± 15.4 vs. 17.7 ± 10.5 mg/dl; P = 0.001). Similarly, serum creatinine (2.2 ± 0.8 vs. 1.6 ± 0.7 mg/dl; P = 0.005) and serum BUN (49.4 ± 23.3 vs. 31.1 ± 19.7 mg/dl; P = 0.003) were significantly lowered by the HepaWash® procedure. There were no serious adverse events observed in conjunction with the HepaWash® treatment.

**Conclusion** So far the HepaWash® system has proven to be a safe and feasible procedure to effectively eliminate water and protein-bound toxins in humans with LF.

**P384**

**Intensive care referral and admission: do the criteria for liver disease match?**

J McPeake, CR Soulsby, T Quasim, J Kinsella

University of Glasgow, UK

**Introduction** Hospital admission and mortality rates for patients with cirrhosis in the UK are rising [1]. Cirrhotic patients are physiologically challenged and at increased risk of sepsis and death [2]. Mortality rates for cirrhosis in nontransplant ICUs are up to 37% [3]. Increased availability of medical therapies and public expectation places pressure on limited intensive care resources. There is a lack of research into factors used to decide which patients to admit or refer to the ICU.

**Methods** A prospective survey was sent to all consultant gastroenterologists and consultant intensivists in Scotland. Each recipient rated the significance of 18 physiological and social criteria on their decision to refer or admit a patient to intensive care from 1 to 5, with 1 being no influence and 5 denoting significant impact on the
decision. Recipients listed additional criteria used in their own practice and asked whether they would admit or refer individual grades of Child–Pugh cirrhosis with either a gastrointestinal bleed or sepsis.

**Results** Thirty-five consultant gastroenterologists and 65 intensive care consultants responded, representing a response rate of 34% and 45% respectively. The only criterion given an average rating of 5 by both gastroenterologists and intensivists was Child–Pugh score when stable. Presence on the transplant list, referral secondary to bleeding varices, recent discharge from the ICU, abstinence from alcohol, nutritional status, age under 30 and more than one additional organ failure all scored 4 or 5 from both groups. Sex, employment, smoking or drug use, deprivation and positive virology status did not influence the decision to refer or admit patients. Clinicians reported compliance with medication and outpatient appointments plus an obvious precipitant factor as important features in their decision. The majority of respondents would refer or admit all grades of Child–Pugh cirrhosis with gastrointestinal bleeding. Most would refer or admit Child–Pugh A or B with sepsis. A total 76.5% of gastroenterologists would refer Child–Pugh C cirrhosis with sepsis but only 33.3% of intensivists would accept.

**Conclusion** Referral and admission decisions for patients with cirrhosis are multifactorial. Child–Pugh status when stable appears to be of greatest significance. The difference in opinion of admission of patients with Child–Pugh C with sepsis requires further evaluation.

Mortality in patients with cirrhosis admitted to the ICU: time to rethink strategies?

A Vaz, M Eusebio, A Antunes, A Sousa, P Perez, R Omelas, C Granja, H Guerreiro

Centro Hospitalar do Algarve, Faro, Portugal

**Introduction** Cirrhotic patients admitted to the ICU are usually regarded as having a particularly poor prognosis when compared with other groups of critically ill patients. The aim of our study was to evaluate the prevalence, case mix and outcomes of patients with cirrhosis admitted to the general ICU of a nontransplant center.

**Methods** Data were collected from a running ICU database. We studied cirrhotic patients admitted to the ICU between January 2013 and November 2014.

**Results** A total of 30 patients with cirrhosis were admitted, accounting for 3% of total ICU admissions. Mean age was 54.5 years, with a male preponderance (76.7%). The main cause for cirrhosis was alcohol (53.3%), followed by alcohol plus chronic hepatitis C Virus (HCV) infection (20%) and HCV virus infection alone (13.3%). The most common causes for admission were sepsis/septic shock (26.7%), surgical (23.4%), gastrointestinal bleeding and hepatic encephalopathy (16.7% each). At admission, these patients presented an average Model for End-Stage Liver Disease score of 23.5 ± 10.4 with 70% classified as grade C in the Child–Pugh score; mean Acute Physiology and Chronic Health Evaluation (APACHE II) 29.2 ± 8.7 and new Simplified Acute Physiology Score (SAPS II) 62.7 ± 29. Regarding organ failure at admission, the mean Sequential Organ Failure Assessment score was 12.8 ± 4.5. The ICU mortality of these patients was 43.3% and hospital mortality was 53.3%. The variables at admission that related significantly with ICU mortality were: all scores described except for Child–Pugh score, bilirubin, the International Normalized Ratio, creatinine, bicarbonate, lactate, pH and the use of renal replacement therapy during the ICU stay (P < 0.05). The mortality rate of cirrhotic patients was superior to the general ICU mortality (43% vs. 26%). However, patients with cirrhosis presented significantly higher severity scoring systems (APACHE II; SAPS II) at admission compared with noncirrhotics, with high prevalence of organ dysfunction as assessed by SOFA score.

**Conclusion** The high severity of disease in conjunction with the high mortality rate observed in this group of patients should make us consider the possible benefits of earlier referring/admission to the ICU, ideally before multiorgan failure arises. On the other hand, in nontransplant centers where cirrhotic patients constitute a small percentage of total ICU admissions, the complexity and peculiarities of the management of these patients should prompt their early transfer to a specialized center.

**P386**

Intraabdominal pressure in critical burn patients

PM Millan

Hospital Universitario La Paz, Madrid, Spain

**Introduction** The aim was to study the evolution and incidence of intraabdominal hypertension in critical burn patients using a slightly restrictive fluid therapy protocol based on monitoring transpulmonary thermodilution and lactic acid.

**Methods** A prospective study of 132 consecutive patients admitted to the Critical Burn Unit between October 2008 and October 2011. In all of them resuscitation was performed by objectives: blood pressure (>65 mmHg), hourly diuresis (0.5 to 1 cm³/kg), lactic acid clearance and thermodilution transpulmonary parameters (CI >2.5 l/minute/m², ITBI: 600 ml/m²). We performed measurements of IAP with a bladder catheter every 8 hours in the first 72 hours.

**Results** Ninety-eight men and 34 women were studied. Mean age 48 ± 18 years and a TBSA of 35 ± 22%. The fluid provided by %TBSA in the first 8 hours was less than predicted by Parkland (4.05 ml/kg), although the total contribution in the first 24 hours was similar. The evolution of the intra-abdominal pressure was: admission 9.7 mmHg, 8 hours 11, 16 hours 10.5, 24 hours 12.1, 32 hours 12.0, 40 hours 12.0, 48 hours 11.1, 56 hours 10.3, 64 hours 10.0 and 72 hours 10.0. A total of 44 patients (33.3%) had a determination higher than 12 mmHg, distributed: 15 patients between 12 and 15 mmHg (IAHT I grade), 14 between 16 and 20 mmHg (III), nine between 21 and 25 mmHg (III) and six >25 mmHg (IV). See Figures 1 and 2.

**Conclusion** IAHT incidence when a slightly restrictive fluid protocol used is less than expected.
P387
Intra-abdominal hypertension in burn patients
Trauma and Burn Centre of Tunis, Tunisia

Introduction Intra-abdominal hypertension (IAH) is frequent in the ICU and has been associated with adverse outcomes and worse prognosis. The purpose of our study was to assess risk factors for IAH and prognosis of major injured patients during burn resuscitation.

Methods Adult burned patients with a burn injury exceeding 20% of total body surface area, from 1 April to 30 November 2013, were included. IAP was measured when IAH was suspected, according to the Kron method via the Foley catheter. Monitoring of IAP was performed every 6 hours during 5 days until normalization.

Results Twenty patients were enrolled in the study. The mean age was 36 ± 13 years. There were 14 males and six females. The average TBSA was 44 ± 17%. Screening and monitoring of IAP were applied: oliguria (42%), abdominal distension (31.5%) and gastrointestinal trouble (21%). IAH occurred between day 2 and day 3 after early burn resuscitation, respectively in 52% and 63%. IAH was observed in 69% of cases in patients admitted to the ICU with a delay of 1.6 days after injury: 8 kg for G1 versus 2 kg for G2 (P = 0.04), occurrence of ARDS (70% for G1 vs. 16.7% for G2, P = 0.02), respiratory failure (77% for G1 vs. 28.5% for G2, P = 0.06), shock (70% for G1 vs. 16.7% for G2, P = 0.02) and mortality (61.5% vs. 50%).

Conclusion IAH was frequent in early burn resuscitation of major injured patients. It seems to be associated with fluid overload in burns and contributes to organ damage.

Effects of sepsis on respiratory mechanics in a porcine model of intra-abdominal hypertension
B Fyntanidou, K Kotzampasi, M Kyprassia, G Stavrou, E Oloktsidou, X Mpesis, K Papapostolou, V Grousomanidis
Aristotle Medical School, Thessaloniki, Greece

Introduction The aim of our study was to investigate the effects of sepsis on respiratory mechanics in a porcine model of intra-abdominal hypertension (IAH).

Methods Sixteen pigs were divided into two groups of eight (G-A/ G-B). All animals received general anesthesia and were mechanically ventilated. Parameters recorded included respiratory system, chest wall and lung compliance (CRS, CCW, CL) and respiratory system and chest wall inspiratory and expiratory resistances (RRSisp, RRSexp, RCWisp, RCWexp). After baseline measurements (0 minutes), intra-abdominal pressure IAP was raised by helium insufflation to 25 mmHg in both groups and remained at that level for the whole study. In G-B, sepsis was induced 60 minutes after IAP increase, by i.v. administration of Escherichia coli endotoxin. Parameters were recorded every 20 minutes. The last measurement was made at 180 minutes, right after deinsufflation, and IAP return to baseline levels.

Results CRS decreased statistically significantly in both groups after IAP increase and increased after deinsufflation only in G-A. Similarly, CCW decreased in both groups but returned to baseline values in both groups after deinsufflation. CL decreased more significantly in G-B and did not decrease after deinsufflation, whereas RRSexp increased in both groups, in a more significant manner in G-B, and decreased only in G-A after deinsufflation. RCWisp and RCWexp did not show any alterations during the study period. Results are depicted as mean values ± SD in Tables 1 and 2.

Conclusion Both sepsis and IAH have negative effects on respiratory mechanics. However, their combination has even more detrimental effects, which do not ameliorate after deinsufflation.
Severity markers in acute pancreatitis
S Jalkanen
University of Turku, Finland

Introduction CD73/ecto-5’-nucleotidase is an enzyme that generates adenosine, which dampens inflammation and improves vascular barrier function in several disease models. CD73 also circulates in a soluble form in the blood [1]. We studied whether levels of soluble form of CD73 and cytokines/chemokines predict the development of organ failure in acute pancreatitis [2,3].

Methods Altogether, 161 patients with acute pancreatitis (107 were subclassified according to the revised Atlanta criteria into mild, 29 into moderately severe and 25 into severe forms) were studied. Serum and blood cell samples were collected at admission. Protein levels of soluble form of CD73 in serum were determined using a novel enzyme-linked immunosorbent assay, activity of soluble form of CD73 using radioactive enzyme assays, and CD73 messenger RNA levels from leukocytes using quantitative PCR. Serum levels of 48 cytokines and growth factors were determined using Bio-Plex Pro Human Cytokine Assay 21-plex and 27-plex magnetic bead suspension panels.

Results Activity and protein concentration of soluble form of CD73 and messenger RNA level of CD73 all decreased along with the disease severity (P<0.01 for all). The activity of soluble form of CD73 at admission predicted the development of severe pancreatitis in different groups of the patients. Especially, activity of soluble form of CD73 was better than C-reactive protein or creatinine in predicting the severity of pancreatitis in the group of patients without any signs of organ failure at admission. In subgroup analyses of patients with severe pancreatitis and without organ dysfunction upon admission, IL-8, hepatocyte growth factor and granulocyte colony-stimulating factor (G-CSF) levels predicted the development of severe pancreatitis, with G-CSF being the most accurate cytokine.

Conclusion Activity of soluble form of CD73 and levels of certain cytokines at admission to the hospital have prognostic value in predicting the development of the severe form of acute pancreatitis. The possibility that combining them with other prognostic markers might improve prognostic accuracy requires further studies.

well. Gene expression of SOCS3 was positively related with circulating IL-6 in the P group but not in the placebo group (Figure 1).

Conclusion The studied P formulation significantly decreased the risk of postoperative complications, namely mechanical ventilation, infections and anastomotic leakage. Modulation of the gene expression of SOCS3 is one suggested mechanism.

**P391**

Role of ultrasonography in detection of the localization of the nasoenteric tube

R Dagli¹, H Bayir², Y Dadalı¹, T Tokmak¹, Z Erbesler¹

¹Ahi Evran University Education and Research Hospital, Kirsehir, Turkey; ²Abant Izzet Baysal University, Medical School, Bolu, Turkey

Introduction In this study, we aimed to determine the success rate of nasoenteric tube (NET) insertion into the postpyloric area by ultrasonography (USG) and compare it with the commonly used method, direct abdominal radiography.

Methods Patients admitted to an adult ICU between April and July 2014 with an indication for NET insertion for enteral feeding were included in the study after informed consent was given from patients’ relatives. Nasoenteric feeding tubes were placed using the blind bedside method by a single anesthesiologist. Any motility stimulant agent was not used. The outside of the polyurethane 8 F with unweighted NET (Bexen, Spain) and its guiding wire were lubricated with gel. The NET was inserted into the nostril after determination of the mouth–nose distance and pushed on at least such a distance. Followed by auscultation of the gastric area and air infusion of 30 to 50 ml into the tube, the patient was positioned on their right side and the tube was advanced 20 to 30 cm more. Then the guiding wire inside the NET was removed. The patient was then brought to the supine position and NET was visualized by two radiologists simultaneously by MS portable USG (Mindray, PRC), with a 3.5 MHz convex probe whether it passes through the postpyloric area or not. Localization of the tube was confirmed with abdominal radiography in all patients. During the first insertion of the NET, the ratios for inaccurate localization and correct placements through the postpyloric area were recorded and results were compared with abdominal radiography.

Results In this study, the bedside blind method was used for NET insertion into 34 patients. Eleven of the tubes were detected passing through the postpyloric area by USG. In one case the NET could not be seen in the postpyloric area by USG, but it was detected in the postpyloric area by control abdominal radiography. In 22 patients, NETs were detected in the stomach with control abdominal radiography. Success for NET placement with the bedside blind method and USG imaging was 35% versus 91.6%, respectively.

Conclusion The success rate of the bedside blind method in the NET placement was low. It is clear that if any other placement techniques with high success rate will be applied, USG will be useful in a higher success rate will be applied, USG will be useful in a higher number of patients reducing the need for abdominal radiography.

**P392**

Thiamine as a metabolic resuscitator in septic shock: a randomized, double-blind, placebo-controlled, pilot trial

M Donnio¹, LW Andersen², M Chace³, RM Berg¹, TA Giberson¹, H Smithline¹, M Tidswell⁴, R Woff³, M Cocchi¹

¹Beth Israel Deaconess Medical Center, Boston, MA, USA; ²Bayside Medical Center, Springfield, MA, USA

Introduction The objective was to determine whether the administration of thiamine mitigates elevated lactate levels in patients with septic shock. Thiamine is essential for aerobic metabolism and we have found that thiamine levels are low and inversely correlated with lactate levels in patients with sepsis.

Methods We performed a randomized, double-blind, placebo-controlled, two-center trial from January 2010 to October 2014. We enrolled patients with septic shock, elevated lactate (≥3 mmol/l) and no obvious competing cause of lactate elevation. Patients received thiamine 200 mg or placebo i.v. twice/day for 7 days. The primary outcome was lactate levels at 24 hours. Secondary outcomes included the SOFA score at 24 hours and mortality. Lactate levels at 24 hours were compared between patients using the Wilcoxon rank-sum test and categorical variables were compared using the Fisher’s exact test. Lactate values at 24 hours, for those who died before 24 hours, were imputed according to a predefined plan. We performed a preplanned analysis in those with baseline thiamine deficiency (≤7 nmol/l).

Results We enrolled 88 patients; 43 received thiamine and 45 placebo. Baseline characteristics were similar between the groups. We found no overall statistical significant difference in 24-hour lactate levels between thiamine and placebo groups (2.5 (IQR: 1.5 to 3.4) vs. 2.6 (IQR: 1.6 to 5.1), P = 0.40). Fewer patients in the thiamine group had lactate levels >4 mmol/l at 24 hours (21% vs. 38%, P = 0.10) and this was statistically significant if only evaluating survivors at 24 hours (7% vs. 33%, P = 0.03), although our preplanned analysis was to impute data. We found no difference in 24-hour SOFA score or mortality. A total of 28 (35%) patients were thiamine deficient. Of the deficient patients, those receiving thiamine had statistically significant lower lactate levels at 24 hours (2.1 (IQR: 1.4 to 2.5) vs. 3.1 (IQR: 1.9 to 8.3), P = 0.03) and more patients in the placebo group had a lactate >4 mmol/l (38% vs. 7%, P = 0.07). Mortality in the thiamine and placebo groups was 13% and 46%, respectively (P = 0.10).

Conclusion Thiamine deficiency is prevalent in septic shock. Thiamine did not decrease overall median lactate levels at 24 hours. In the patients with thiamine deficiency, there were statistically significant lower lactate levels at 24 hours in the thiamine group and a large, although nonsignificant, difference in mortality.

**P393**

Unraveling the link between malnutrition and adverse clinical outcomes: association of acute and chronic malnutrition measures with blood biomarkers from different pathophysiological systems

S Felder, N Braun, A Kutz, M Batscharoff, P Schuetz

Kantonsspital Aarau, Switzerland

Introduction Malnutrition is common in hospitalized medical patients and is associated with poor clinical outcomes. Whether malnutrition has a direct link to adverse outcomes or is rather a mirror of the underlying disease remains debated. Our aim was to study the association of acute and chronic malnutrition status with blood biomarkers from different pathophysiological concepts to better understand the underlying mechanisms of malnutrition.

Methods We prospectively followed consecutive adult medical inpatients hospitalized between February 2013 and October 2013 in a tertiary care Swiss hospital. Nutritional risk was assessed using the Malnutrition Universal Risk Screening (MURS) score, which incorporates acute and chronic measures of malnutrition. Multiaj usted regression models were used to investigate the associations between acute and chronic nutritional risk and biomarkers mirroring inflammation (CRP, PCT, proADM, leptocyes), stress (corticotropin), renal dysfunction (creatinine, urea), nutritional status (vitamin D25, albumin, calcium, glucose), and hematological function (platelets, INR, Hb, RDW). Biomarker levels were transformed into deciles due to skewed distributions.

Results A total of 529 patients (mean age 72 years, 57.1% male) were included. Overall, there was a significant association of NRS and most biomarkers of inflammation, stress, renal function, nutrition and the hematological system (coefficient and 95% CI): CRP 0.021, P = 0.0021, PCT 0.28, P = 0.003, proADM 0.4, P < 0.001, copeptin 0.44, P < 0.001, urea 0.28, P = 0.002, vitamin D25 –0.23, P = 0.012, albumin –0.6, P < 0.001, hemoglobin –0.5, P < 0.001, RDW 0.46, P < 0.001. These associations remained robust after adjustment for sociodemographics (model 1), comorbidities (model 2) and main medical diagnosis (model 3). Subgroup analysis suggested that mainly the acute part of malnutrition was associated with an increase in biomarker levels.

Conclusion Acute malnutrition was associated with a pronounced inflammatory response and an increase in biomarkers from different pathophysiological systems which may partly explain the link between malnutrition and adverse medical outcomes. However, interventional trials are needed to prove causal relationships.
P394 Evaluation of the provision of nutrition in a South African provincial hospital
S Kudsk-liesen, R Matos-Puig, R Naidoo, S Moorad
Stanger General Hospital, Stanger, South Africa

Introduction The provision of nutrition in the critical care unit (CCU) has shifted from nutrition support to nutrition therapy, and the potential benefits derived from this in the recovery of the critically ill is being explored [1]. We audited the management of nutrition in the CCU in a South African Hospital against the American Society of Parenteral and Enteral Nutrition Guidelines. Furthermore, we reviewed the knowledge and confidence of healthcare providers in the management of nutrition in the CCU.

Methods Retrospective data collection of patients admitted to a four-bed CCU over a 4-month period in 2013. A survey was distributed to different disciplines involved in patient nutrition in the CCU.

Results Seventy-two patients were admitted to the CCU during this time period, and notes were able for 44. Three paediatric patients were excluded. Twenty-nine patients stayed for 2 or more days (the audit population). The median age of the audit population was 38, 19 were female. Sixteen were surgical admissions. The median APACHE II score of the patients with sufficient available data (n = 16) was 14 (range 6 to 34). The audit found that 21 of the patients had nutrition started in the CCU, with 15 having nutrition started within 48 hours. Only eight patients had a nutritional assessment done. A total of 45 responded to the survey: eight anaesthetists, 25 from surgical disciplines, seven CCU nurses, and five dieticians. All agreed that nutrition should be started in the first 48 hours, except from the surgeons only 14 (56%) agreed. The average self-rating of knowledge of nutrition management in the CCU (1 = lowest, 5 = highest) was 2.1 with the dieticians and CCU nurses showing the highest confidence with 3.4 and 2.6, respectively. The anaesthetists rated their knowledge at 1.9 and the surgeons rated themselves at 1.8.

Conclusion We found that there is poor management of nutrition in the CCU. This is paired with limited knowledge and low confidence in management amongst the attending staff. Evidence would suggest that the development and dissemination of clear hospital guidelines could improve rates of correct management [2]. However, the lack of uniform guidance based on strong evidence from the leading global authorities on nutrition suggests that, in order to improve implementation of adequate nutrition, more research is urgently required.

P395 Quality improvement project to optimize enteral nutrition in a tertiary hospital’s surgical ICU
J Li, LY Koh, JH Yang, C Khoo, T Ter, BH Tan
National University Health System, Singapore

Introduction Optimizing enteral nutrition early has been shown to be beneficial in critically ill patients. However, underfeeding is still a common problem. The critically ill surgical patient often presents with additional challenges to optimal enteral feeding. The objective of this study was to improve enteral feeding practices in a surgical ICU. The quality improvement methodology was employed. An audit was carried out to determine the problem of underfeeding in the unit. Root cause analyses were conducted and team members identified key barriers to optimal feeding and areas for improvement. Protocols were developed to standardize and encourage early enteral feeding as well as to reduce the time feeds are interrupted for patients who were going for surgeries or for various other reasons. Educational interventions were conducted with lectures to physicians and nurses. Visual aids in the form of screen savers at each bedside computer served as reminders to the team to optimize feeding. A subsequent audit was then conducted to determine the improvement in achieving the desired outcomes, namely the amount of calories and proteins received as well as the proportion of patients who achieved >70% of their target calories and proteins. We considered target calories to be 25 kcal/kg/day and target proteins to be 1.5 g/kg/day.

Results Patients received more calories (78.3% vs. 59.1%) and more proteins (70.2% vs. 54.6%) post implementation. The mean percentage of patients in the post group who achieved >70% of required calories was 80.1% versus 30.9% in the pre group. The mean percentage of patients who achieved >70% of required proteins was 58.3% versus 32.1% in the pre group.

Conclusion The multipronged approach of the quality improvement methodology helped to increase the provision of calories and proteins in our population of critically ill surgical patients. However, there is still room for improvement in terms of achieving optimal enteral nutrition targets early in our population. There is also a need to look into sustaining such results.

P396 Could preoperative and postoperative optimal nutrition support modulate the inflammatory response and clinical outcome of severe malnourished surgical patients with gastrointestinal neoplasia?
L Mirea, D Pavelescu, I Grintescu
Emergency Hospital Floreasca, Bucharest, Romania

Introduction Our aim was to assess whether perioperative and postoperative optimal 7-day nutrition support could modulate the inflammatory status and clinical outcome of severe malnourished patients with surgery for gastrointestinal neoplasia.

Methods A prospective randomized study of 64 patients with gastrointestinal neoplasia, severe malnourished BMI <18.5, albumin level <3 g/dl, BW loss >10%, NRS >3, scheduled for surgery, allocated into two groups. Group A: 32 patients, minimal enteral nutrition in the postoperative period according to tolerance, medium 500 kcal/day. Group B: 32 patients received optimal parenteral nutrition support (25 kcal/kg/day) 3 days before surgery and continued for at least 4 days postoperatively. We measured CRP, fibrinogen, IL-6, TNF, albumin level preoperatively and at 96 hours, the incidence of complications, and the length of ICU stay.

Results There was a significant decrease in the values of CRP, IL-6, TNF, albumin at 96 hours in group B. No difference in fibrinogen. A significantly lower rate of complications and a shorter time of ICU stay were observed in group B. See Figures 1 and 2 (overleaf).

Conclusion Perioperative optimal nutrition support for at least 7 days could modulate the inflammatory status and clinical outcome of severe malnourished surgical neoplastic patients.

P397 Does discontinuation of the use of hydroxyethyl starches in the critically ill cardiac surgery patient have an impact on caloric intake?
E De Waele, K De Bondt, S Mattens, J Czapla, J Nijs, M La Meir, D Nguyen, PM Honore, H Spapen
Universitair Ziekenhuis Brussel, Brussels, Belgium

Introduction After research revealed unwanted effects of the use of starches in critically ill patients, its use in the immediate postoperative period of cardiac surgery patients came to an abrupt ending. However, they constitute an important source of non-intended calories, providing 4 calories per gram. We investigated whether this phenomenon (involuntary) attributed to an increase in caloric debt for this critically ill patient population.

Methods We retrospectively searched a database of 417 elective cardiac surgery patients, representing 5,004 observation-days. Caloric
intake was evaluated in the group of patients before and after the cessation of starch use.

**Results**

Patient characteristics and caloric needs were comparable: 2,054 ± 395 kcal/day and 2,056 ± 347 kcal/day. The 140 patients who in the immediate postoperative period had volume resuscitation without the use of starches had a mean non-intended fluid caloric intake of 69 (± 36.3) kcal/day. The group of 277 patients who received starches in the postoperative period had a mean non-intended fluid caloric intake of 105 (± 100.2) kcal/day.

**Conclusion**

Withdrawal of the use of starches resulted in a 34% decrease of non-intended caloric intake by fluids, contributing to caloric debt. Whether outcome is influenced and/or whether these findings are clinically relevant needs further research.

P398

**NUTRIC score in oncologic patients**

A Patrão, L Bei, F Coelho

Instituto Português de Oncologia – Porto, Portugal

*Critical Care* 2015, Volume 19 Suppl 1; http://ccforum.com/supplements/19/S1

**Introduction**

The NUTRIC score is a tool designed to quantify the risk of critically ill patients developing adverse events that may be modified by aggressive nutrition therapy, in the general population of an ICU. Cancer patients are more prone to be at nutritional risk due to the disease and treatment complications. Our aim was to characterize NUTRIC score behavior in the population of patients admitted to an oncologic ICU.

**Methods**

Between January and June 2014 we applied the NUTRIC score to all patients, age >18 years, without cerebral death criteria and with a length of stay (LOS) > 72 hours. Data were collected and analyzed using SPSS v20.0. To evaluate the impact on mortality we used logistic regression.

**Results**

Sixty-nine patients were included, 23 women (33.3%) and 46 men (66.7%). Most patients were aged between 50 and 75 years (72.5%) and had normal range weight 58% (n = 40). The mean LOS was 11.56 (minimum: 3 to maximum: 69). The most common motive for admission was sepsis (7.7%, n = 26). APACHE II score was above 15 in 77% of the patients (n = 53) and SOFA score was superior to 6 in 56.5% (n = 30). The NUTRIC score was low risk in 42% (n = 29) of the patients and high in 58% (n = 40). Twenty-eight-day mortality was 26.1% (n = 18). A high NUTRIC score corresponded to a 22-fold increased odds of dying in the first 28 days (P < 0.001). Both APACHE II and SOFA were mortality predictors alone, with an increase of 1 point in APACHE score corresponding to an increase of 14% (P = 0.002) and an increase of...
1 point in SOFA corresponding to an increase in the odds of being dead at 28 days ($P = 0.002$). Body mass index, age, number of comorbidities, and days in the ICU did not correlate with mortality.

Conclusion The NUTRIC score is a good tool in cancer patients to predict 28-day mortality. Nevertheless, the only compounds of the NUTRIC score that correlated independently with mortality were APACHE II and SOFA scores. Further investigation towards the inclusion of other categories such as tumor staging and the type of tumor could be useful to develop a specific prognostic tool for this population.

### P399

**Early calorie-dense immune nutrition in haemodynamically compromised cardiac patients**

S Efremov, V Lomivorotov

Research Institute of Circulation Pathology, Novosibirsk, Russia

Introduction The aims of present study were to test the hypothesis that early enteral nutrition (EN) with calorie-dense food supplemented with glutamine improves recovery of nutritional status in critically ill cardiac patients and to evaluate their resting energy expenditure (REE).

Methods A prospective randomised study of 40 adult cardiac patients undergoing elective cardiopulmonary bypass surgery no more than 24 hours before eligibility assessment, complicated with acute heart failure syndrome. Patients were randomised to receive either standard isocaloric isonitrogenic early EN (standard group, $n = 20$) or immunomodulating early EN (immune group, $n = 20$). The daily energy target was set using REE measured by indirect calorimetry (CCM Express; Medgraphics, St. Paul, MN, USA). Serum prealbumin, transferrin, C-reactive protein, blood lactate and clinical characteristics were analysed.

Results The actual REE was an average of 6.8 and 7.5 kcal/kg/day higher than the REE calculated using the Harris–Benedict equation for gluconeogenesis, eventually resulting in cachexia. This finding poses severe metabolic challenges for ICU patients in which interfering with recovery can contribute to poor survival. In light of our findings, re-evaluation of nutritional protocols and potential anabolic/anti-catabolic therapy to decrease muscle catabolism may improve survival.

Different therapeutics that may prevent hypermetabolism (such as beta-blockers) should be re-evaluated along with anabolic agents (that is, oxandrolone) which could counteract the severe catabolic response in critical illness. Monitoring of muscle glutamine repletion could signal the transition from the catabolic to anabolic phase.

### P400

**Measurement of skeletal muscle glycogen status in critically ill patients: a new approach in critical care monitoring**

I San Millan, J Hill, P Wischmeyer

University of Colorado, Aurora, CO, USA

Introduction Critically ill patients experience hypermetabolism increasing substrate utilization, especially glucose oxidation. Glycogen is the main source of glucose in the body, being 85% and 15% stored in skeletal muscle and liver respectively. Since glycogen stores are limited we evaluated the hypothesis that critical illness could be associated with glycogen depletion leading to skeletal muscle catabolism for gluconeogenesis and eventually resulting in cachexia, an important determinant of future ICU survival and ICU-acquired weakness.

Methods Nine critically ill patients ($58.75 \pm 25$ to 75 years old) with an ICU stay from 1 day to 5 weeks were evaluated for skeletal muscle glycogen content using a rapid, non-invasive high-frequency ultrasound methodology (MuscleSound®, Denver, CO, USA). Scans were obtained from the rectus femoris and vastus lateralis muscles. Glycogen content was measured with a score from 0 to 100 according to the MuscleSound® scale. Patients had a variety of primary diagnoses including septic shock ($n = 3$), hemorrhagic shock/abdominal hypertension ($n = 3$), hypovolemic shock/post major oncologic surgery ($n = 1$), trauma ($n = 3$), and burn injury ($n = 1$).

Results Six out of nine patients had no glycogen present in the muscle (score = 0). The other three patients had glycogen scores between 5 and 15 which are well below scores of healthy individuals (reference 50 to 70). As a comparison we collected post-competition levels in competitive athletes, which decrease their glycogen stores (score 15 to 25) but are well above those of most critically ill patients we have studied.

Conclusion This is the first time that muscle glycogen stores have been evaluated in critical illness. Our data show severe glycogen depletion in ICU patients which probably leads to muscle catabolism necessary for gluconeogenesis, eventually resulting in cachexia. This finding poses severe metabolic challenges for ICU patients in which interfering with recovery can contribute to poor survival. In light of our findings, re-evaluation of nutritional protocols and potential anabolic/anti-catabolic therapy to decrease muscle catabolism may improve survival.

Different therapeutics that may prevent hypermetabolism (such as beta-blockers) should be re-evaluated along with anabolic agents (that is, oxandrolone) which could counteract the severe catabolic response in critical illness. Monitoring of muscle glycogen repletion could signal the transition from the catabolic to anabolic phase.
I reduced infections (RR 0.64; 95% CI, 0.44 to 0.92; infections were aggregated, FO-containing emulsions significantly overall mortality was found. When the results of five RCTs that reported heterogeneity in interventions tested in these trials. No effect on over the last year, met inclusion criteria. There was considerable patients that evaluated FO-based LEs in parenteral nutrition (PN) or ventilation (MV) days. We included RCTs conducted in critically ill adult.

</table>

Mean ± SD or median (IQR). *P<0.01.

(P <0.001). There appeared to be a significant correlation between the APACHE IV score and glutamine levels (R = 0.52, P <0.001). Moreover, in a backward linear regression analysis this correlation was independently associated with APACHE IV scores and the presence of infection, but not with the type of admission.

**Conclusion** Plasma glutamine levels were significantly lower after acute admission compared with elective surgery. In both groups a considerable amount of patients had decreased glutamine levels, but this was not independently associated with the type of admission. In contrast to previous studies we found that glutamine levels were determined by severity of illness and the presence of an infection.

### P403

**Intravenous fish oil lipid emulsions in ICU patients: an updated systematic review and meta-analysis**

P Langlois1, R Dhaliwal1, M Lemieux1, D Hayland1, W Manzanares1,2

1Hospital Fleurimont, Sherbrooke, QC, Canada; 2Kingston General Hospital, Kingston, ON, Canada

**Introduction** Intravenous fish oil (FO) lipid emulsions (LEs) are rich in ω-3 polyunsaturated fatty acids, which exhibit anti-inflammatory and immunomodulatory effects. We previously demonstrated that FO-containing emulsions may be able to decrease mortality and ventilation days in the critically ill. Over the last year, several additional randomized controlled trials (RCTs) of FO-based LEs have been published. Therefore, the purpose of this meta-analysis was to update our systematic review aimed to elucidate the efficacy of FO-based LEs on clinical outcomes in the critically ill.

**Methods** We searched computerized databases from 1980 to 2014. Overall mortality was the primary outcome and secondary outcomes were infections, ICU and hospital length of stay (LOS), and mechanical ventilation (MV) days. We included RCTs conducted in critically ill adult patients that evaluated FO-based LEs in parenteral nutrition (PN) or enteral feeding. Patients were analyzed using RevMan 5.1 (Cochrane IMS, Oxford, UK) with a random effects model.

**Results** A total of 10 RCTs (n = 733), including four trials published over the last year, met inclusion criteria. There was considerable heterogeneity in interventions tested in these trials. No effect on overall mortality was found. When the results of five RCTs that reported infections were aggregated, FO-containing emulsions significantly reduced infections (RR 0.64; 95% CI, 0.44 to 0.92; P = 0.02, heterogeneity F = 0%). Furthermore, FO-based LEs were associated with a trend toward a reduction in MV days (WMD, –1.41; 95% CI, –3.43 to 0.61; P = 0.17, heterogeneity F = 0%), and hospital LOS (WMD –4.06; 95% CI, –10.14 to 2.03; P = 0.19, P = 89%, P <0.0001), without effect on ICU LOS. See Figure 1.

**Conclusion** FO-based LEs may be associated with a reduction in infections, as well as clinically important reductions in duration of ventilation, and hospital LOS. Nevertheless, according to current literature there is inadequate evidence to give a final recommendation on the routine use of FO-containing emulsions in PN and/or as a pharmaceutic strategy in enterally fed critically ill patients. Further large-scale RCTs which should aim to consolidate potential positive treatment effects are warranted.

### P404

**Glutamine administration in sepsis: enteral, parenteral or both?**

Experimental study in swine

1Aristotle University of Thessaloniki, Greece; 2Democritus University of Thrace, Alexandroupolis, Greece

**Introduction** Glutamine (GLN) is recommended in the critically ill for i.v. administration but enteral use is not quite clarified. We decided to measure GLN plasma levels in healthy and septic swine after GLN given by i.v., enteral or both routes, over a 3-hour period.

**Methods** Sepsis was induced by E. coli LPS. GLN was infused: i.v. through the femoral vein (0.5 g/kg); enterally (E) through jejunostomy (0.5 g/kg) and i.v. + E. Blood was drawn continuously from the femoral artery and the portal vein for GLN plasma levels in systemic-S and portal-P circulation.

**Results** In healthy swine, GLN levels remained stable, both in S and P; i.v. infusion, and even more i.v. + E significantly increased GLN in the S circulation (P <0.001), whereas E infusion failed to do so (P = 0.4). On the contrary, GLN P levels were significantly increased after i.v. + E infusion, as well as after E infusion (P <0.001) and to a lesser extent, after i.v. infusion (P <0.001). In sepsis, both S and P GLN levels decreased significantly.

Prehospital factors associated with an ICU admission from the emergency department
TA Williams1, TF Finn1, D Fatovich1, D Brink1, KM Hao1, H Tohira1
1Curtin University, Bentley, Australia; 2Royal Perth Hospital, Perth, Australia

Introduction
This study aimed to describe the patient characteristics and prehospital factors associated with an ICU admission from the ED. There is a paucity of information about the early recognition of critical illness by paramedics; especially in the Australian prehospital setting.

Methods
A retrospective cohort study, July 2012 to June 2014, conducted in the Perth metropolitan area, which is served by a single ambulance service. Adult patients were included if transported to a public hospital ED that used the ED information system (EDIS) (seven of eight EDs) and were admitted to the ICU from the ED (ED-ICU group). Patients aged <16 years, those from rural areas or transfers were excluded. We used existing ambulance clinical data linked to EDIS data. Prehospital cohort characteristics are described using univariate statistical techniques. Logistic regression was conducted with admission to the ICU from the ED (critical illness surrogate) as the outcome variable. Variables included in regression models were age, sex, paramedic-identified urgency, that is the time patients should be seen by a doctor based on the Australasian Triage Scale, paramedic-identified patient problem and the time taken from the ambulance service receiving the call to hospital arrival.

Results
Overall selection of flowcharts was accurate for 94.1% of scenarios at T0 and 98.7% at T1. Triage category selection was correct for 93.3% of scenarios at T0 and 98.4% at T1. Both flowchart selection and triage category were correct in 89.5% case in T0 and at 97.5% T1. When an incorrect flowchart was used, triage category remained accurate in 64.9% and 70.5% respectively. Both flowchart and triage selection accuracy improved significantly from T0 to T1 (P < 0.0001).

Conclusion
The results of the present study revealed that using the SALOMON algorithm is reliable for out-of-hours PCP call triage by nurses. Validity of this rule may be further evaluated through its actual implementation in real-life conditions.

Adequacy of trained assistance, emergency equipment and drugs at emergency calls in the ICU and in remote areas of the hospital
I Kolic1, S Unell1, A Watts2, A Barry2, J Short2
1South London Healthcare NHS Trust, London, UK; 2Lewisham and Greenwich NHS Trust, London, UK

Introduction
We aimed to identify the adequacy of assistance provided and to assess correct anaesthetic equipment and drug availability at emergency calls made in the ICU and in remote areas of the hospital. Emergency calls often involve managing critically ill patients with the highest mortality results. The importance of a clinical team with the necessary competencies and the right level of resources are paramount.

Methods
We undertook a prospective survey of all adult patients with emergency calls put out to the anaesthetic team in a London district (all P < 0.001) except the time taken from receiving the call to hospital arrival (P = 0.48).

Conclusion
Three-quarters of the ED-ICU patients were transported to the ED with high urgency. Currently no prehospital severity of illness or early warning system (EWS) is used in our ambulance service. Given the small proportion of ED-ICU patients who presented with abnormal observations, it is unlikely that introducing an EWS would alter practice or patient outcome.

P406
Reliability of a new French-language triage algorithm for out-of-hours primary care calls: the SALOMON rule
E Brassot1, A Ghysen1, AF Donneau1, V D’Onorio1
1CHU de Liège, Belgium; 2University of Liège, Belgium

Introduction
Because of increased workloads associated with primary care physician (PCP) shortage, many western countries have been facing the difficult challenge of optimizing their out-of-hours primary care services. PCPs initially gathered in small rotation groups, and then further collaborations led to larger-scale cooperatives. In such models, implementation of patient call triage is mandatory to increase the efficiency, quality and safety of care [1]. Organization models differ, from the PCP performing all patient calls to nurses and nurse assistants answering calls and performing triage, but no validated triage algorithm has been reported to date. We developed a specific French-language triage algorithm called SALOMON (Système Algorithmique Liégeois d’Orientation pour la Médecine Omnipraticienne Nocturne) in order to guide nurse triage PCP out-of-hours calls. The present study tested this algorithm reliability.

Methods
The SALOMON algorithm is based on 53 common presentation flowcharts using specific discriminators to triage calls into four categories according to the level of care required: emergency medical services, nonemergent visit to local emergency department, PCP home visit or PCP delayed consultation. Using an appropriate statistical test, we assessed the accuracy of presentation flowchart and triage category selections attributed to 130 clinical scenarios, by 10 different nurses, in comparison with references established by a local team of experts, at two different time periods: immediately after training (T0) and 3 to 6 months after algorithm practice (T1).

Results
Overall selection of flowcharts was accurate for 94.1% of scenarios at T0 and 98.7% at T1. Triage category selection was correct for 93.3% of scenarios at T0 and 98.4% at T1. Both flowchart selection and triage category were correct in 89.5% case in T0 and at 97.5% T1. When an incorrect flowchart was used, triage category remained accurate in 64.9% and 70.5% respectively. Both flowchart and triage selection accuracy improved significantly from T0 to T1 (P < 0.0001).

Conclusion
The results of the present study revealed that using the SALOMON algorithm is reliable for out-of-hours PCP call triage by nurses. Validity of this rule may be further evaluated through its actual implementation in real-life conditions.

Reference
general hospital over a 6-week period. We performed a snapshot audit of equipment in resuscitation trolleys across each ward and in the radiology department. We compared the data collected on available equipment with the standard set by the Resuscitation Council (UK) Recommended Minimum Equipment Checklist [1]. The survey addressed the availability, clinical competency and appropriate duration of stay of the anaesthetic assistant at the emergency calls. Further qualitative data were collected on the availability of required emergency drugs.

**Results** During the study period 44 emergency calls were attended. Twenty-three (52%) of these calls were in the accident and emergency department, and four (9%) in the ICU. Survey results demonstrated two cases where no anaesthetic assistant arrived at the emergency call put out to them. In cases where timely assistance was available, the assistant did not have the adequate clinical and anaesthetic skills required by the attending physician. In 6% of cases where skilled assistance was required (n = 2), it was felt that the assistant did not stay for the clinically required length of time. Emergency drugs required were found to be not available in 11% of cases (n = 5) and in 17% of cases (n = 6) the necessary emergency equipment was not available. Data were collected on equipment from 17 resuscitation trolleys. The inadequacies identified were the oxygen cylinders were filled less than 75% full in 41% cases (n = 7) and end-tidal capnography was identified to be absent.

**Conclusion** Emergency calls require standards to be met involving the competency of responding team members and adequate resources. This leads us to question whether guidelines should exist regarding the clinical competency and timeliness of the assistant available to the physician at emergency calls.

Use of an electronic early warning score and mortality for patients admitted out of hours to a large teaching hospital

J Bannard-Smith, S Abbas, S Ingleby, C Fullwood, S Jones, J Eddleston
Manchester Royal Infirmary, Manchester, UK

**Introduction** There is widespread concern regarding excess mortality for patients admitted to hospital out of hours. We introduced an electronic track and trigger system (Patientrack) with automated alerts in a large university teaching hospital between 2010 and 2012. The system computes the patient’s early warning score and alerts medical staff via a pager. It is operational 24 hours a day, 7 days a week and could be an effective tool to reduce variations in mortality throughout the working week.

**Methods** We extracted hospital outcome data for all admissions during the financial years between 2007 and 2014. We identified variables that predicted mortality and incorporated them into a multivariate logistic regression model to assess risk of death for admissions in hours (9:00 am to 5:00 pm, Monday to Friday) versus out of hours (all other times).

**Results** Data were available for 1,180,268 hospital admissions, of which 7,264 (0.6%) died. Predictors for hospital mortality included: age, male sex, unplanned admission and admission from supportive care. Risk of death for out-of-hours admissions was not significantly different to in-hours for any year (1.01 (0.92 to 1.11), P = 0.784). There was a significant fall in risk of death over the 7-year period compared with baseline values in 2007/08 (Table 1).

**Conclusion** In our cohort there was no evidence of increased mortality for patients admitted out of hours compared with in hours. This remained true after adjustment for age, sex, emergency admissions and admission source. Our data demonstrated an overall fall in risk of death over the study period. The introduction of Patientrack could have contributed to this reduction in mortality.

Revitalising the medical emergency team call

KP Verma, S Jasioswki, K Jones
1. Melbourne Health, Melbourne, Australia; 2. Ballarat Health Services, Ballarat, Australia

**Introduction** Medical emergency team (MET) calls are quickly becoming an integral part of the response to a deteriorating patient in Australia. Conceptually the MET call response incorporates a structured approach, but in practice this can quickly disintegrate. This collapse of method can leave patients without clear treatment plans and staff disenfranchised. We sought to improve the process of the MET call response at our regional hospital by introducing targeted interventions focused on teamwork, communication, leadership and role allocation.

**Methods** We invited junior doctors and nurses to complete a survey designed by a multidisciplinary MET Call Working Group; 138 staff (40% of population) completed the survey. Based on analysis of responses, a focused three-pronged intervention was formulated and implemented hospital wide. The arms of the intervention were: identification of the name and role of each staff member using highly visible labels; role allocation according to policy written through a multidisciplinary working group; and a time out during the response allowing a structured synopsis of the patient’s current status to be communicated to the team. The intervention was preceded by extensive staff education, and 175 staff (50%) completed the survey 6 months later to assess its success.

**Results** The intervention significantly increased satisfaction amongst staff regarding: identification of the team leader and other key staff members at the response; and time out effectiveness in reducing repetition and improving staff understanding of the patient’s status and medical issues. We found no significant change in staff perceptions regarding the clarity of the ongoing treatment plan at the end of the MET call response.

**Conclusion** Utilising a low-cost intervention in a regional setting, we were successful in improving staff perceptions of role allocation and communication within our MET call responses. The intervention also led to significantly increased overall satisfaction with the MET call system. Through our surveys we have identified other facets of the MET call response that also require attention. Given our encouraging results we are designing a follow-up intervention incorporating structured multidisciplinary training in MET call scenarios.

Successful implementation of a medical emergency team: 2-year experience in a teaching hospital

A Tridente, J Elmore, R Varia, T Mahambrey
St Helens and Knowsley, Liverpool, UK

**Introduction** A medical emergency team (MET) was introduced in our institution in January 2012 to provide timely response to the needs of acutely ill patients and cardiac arrest calls. The MET assesses the patient and prescribes a management plan for the responsible team to follow; promptly stabilising and transferring patients to a place of safety where required. We aimed at evaluating the effects of introducing the MET on clinically relevant processes and outcomes.

**Methods** Prospective data were analysed using STATA 10.1. The primary outcome measure was immediate mortality (defined as mortality at...
conclusion of the MET intervention); the secondary outcome measures were admission to critical care after a MET call and cardiac arrest. **Results** A total of 5,763 MET calls were made between 9 January 2012 and 4 March 2014, of which 5,310 (92.1%) were MET calls, 349 (6.1%) cardiac arrest calls, 36 (0.6%) false alarms and 68 (1.2%) unclassified. The number of calls increased by 32.7% from 2,255 in 2012 to 2,993 in 2013, with all month-specific comparisons showing significant increases in MET activity (ranging from 0.5% to 103.6% increases). MET activity displayed cyclical yearly changes, with the winter months and the month of August (junior doctors’ changeover period) being particularly busy. Median response time (interquartile range) was 1.1 (1 to 2) minutes, with 99.1% calls attended to within 3 minutes. There were 210 (3.64%) immediate deaths (with no significant differences between years), 112 (1.9%) patient transfers to critical care, 233 (4%) patients were transferred to other locations (other than critical care) while 4,697 (81.5%) patients remained on the ward of origin. In 408 cases (7.1%) a do-not-resuscitate order was instituted. On multiple logistic regression analyses, when the type of call was taken into consideration, the response time had no influence on primary (mortality OR = 0.83, 95% CI = 0.63 to 1.09, P = 0.18) and secondary outcomes (admission to critical care OR = 0.85, 95% CI = 0.62 to 1.17, P = 0.33; subsequent cardiac arrest OR = 0.57, 95% CI = 0.27 to 1.2, P = 0.14).

**Conclusion** The MET has been successfully implemented, with demand for its services having increased by 32.7% in 1 year. The unadjusted immediate mortality rate of patients for whom a MET/cardiac arrest call is activated is 3.64%. Response time had no influence on mortality, most probably due to the rapid response time. Immediate mortality was low, probably as a result of early adequate intervention. Further evaluation of overall hospital mortality is warranted for future studies.

**Evaluation of emergency call Code Blue over a 5-year period**

N Bakran, G Karacen, S Tomork, S Keskin

Istanbul Umraniye Training and Research Hospital, Istanbul, Turkey

**Introduction** Code systems are the emergency call and management systems for rapid response in healthcare institutions. The main aim of these systems is to provide common institutional understanding of what is necessary to be done immediately at the time of an event. Code Blue (CB), which is used throughout the world and was described in the 2008 service quality standards of Turkey, defines the necessary emergency intervention in cases of respiratory or cardiac arrest. This study aimed to evaluate the clinical and application data of patients for whom a CB call was made between 2009 and 2013. Approval of local ethics committee, retrospective examination was made of CB forms. The age and gender of the patient, diagnosis, department to which admitted, time of CB call, reason for CB, whether or not CB was appropriate, whether or not CPR was applied, duration of CPR if applied, APACHE II and PRISM scores and predicted mortality were recorded from the hospital automated record system and the CB form. Patients who refused treatment or who could not reach the necessary parameters for the calculation of APACHE II and PRISM scores were excluded.

**Results** From CB calls for a total of 1,195 patients over the 5-year period, 1,035 (86.6%) were evaluated. The rate of erroneous CB was 36.9%. Patients comprised 413 (39.9%) females and 622 (60.1%) males with a mean age of 59.73 ± 23.13 years (range, 0.1 to 102 years). The distribution of total cases over the 5 years (2009 to 2013) was 15.5%, 25.2%, 26.5%, 19% and 13.8% respectively. Distribution according to clinic was emergency internal (37.5%), internal (16.5%) and emergency circulation over death after controlling for age. Of the 203 patients who had true cardiac arrest events, 43 (21.2%) were discharged from the hospital. Good neurological outcome at discharge was seen among 22 (10.8%) of the patients based on Cerebral Performance Category Score.

**Conclusion** The time taken to reach patients conformed with the global standard mean 2 to 3 minutes [1]. The rates of erroneous CB and time to reach patients reduced each year due to more staff exposure and knowledge in CB and the structuring of the emergency clinic.

**Attention Code Blue: a comprehension of in-hospital cardiac arrest from a multispeciality hospital in South India**

M Hisham, MN Sivakumar, T Suresh Kumar, R Senthil Kumar, A Satheesh Kovai Medical Center and Hospital, Coimbatore, India

**Introduction** Numerous American and European studies have associated survival rates in-hospital cardiac arrest (IHCA) with different quality markers. There has been a paucity of studies that explain IHCA in Asian populations. This study was conducted to assess the characteristics and survival among patients suffering from IHCA.

**Methods** All Code Blue activations from 1 January 2012 to 31 December 2012 were analyzed retrospectively. Data were gathered from the Code Blue form and finer details of individual patients were linked through their medical records. Code Blue was activated only for events that happened outside the medical and surgical ICUs.

**Results** A total of 260 Code Blue activations were made, out of which there were 203 true cardiac arrest events among 40,168 in-patients; the cumulative incidence of the same was 0.51%. Mean (SD) duration of arrival of the Code Blue Team (CBT) to the scene was 64.5 (27.7) seconds. Cardiovascular illness was the predominant baseline morbidity but none of the baseline illness showed increased risk of mortality in this group. Among true cardiac arrest events, 92.6% was due to pulseless electrical activity/ asystole and 7.7% was due to ventricular fibrillation (VF)/pulseless ventricular tachycardia (VT); both of these did not have any difference on the initial outcome. But having an initial rhythm of VF/pulseless VT had 90% more chance for discharge from the hospital, with P = 0.04. Although arrival time of the CBT did not have any influence on the final outcome, duration of resuscitation ≥20 minutes had an odds ratio of 10.6 with P < 0.001 favoring return of spontaneous circulation over death after controlling for age. Of the 203 patients who had true cardiac arrest events, 43 (21.2%) were discharged from the hospital. Good neurological outcome at discharge was seen among 22 (10.8%) of the patients based on Cerebral Performance Category Score.

**Conclusion** Our experience shows that out of every 1,000 patients admitted to our hospital, about five sustained cardiac arrest, of whom only 11.3% survived to hospital discharge with good neurological recovery. Variation in the effectiveness of the cardiopulmonary resuscitation quality in comparison with world data could be due to the inherent difference in the severity of the primary illness in the patients and diversity in the reported data.

practices relating to CPR and AED training in London secondary schools.

**Methods** We conducted a registered audit of CPR and AED training in London schools. Secondary schools were identified via web links for each of the London Borough Councils. Telephone interviews with school staff familiar with CPR and AED training practices were conducted prospectively using a standardized web-based survey. All survey response data were captured electronically. We defined universal training as any programme which delivers CPR and AED training to all students in the school. We used simple descriptive statistics to summarise the results.

**Results** A total of 51 schools completed the survey covering an estimated student population of 54,037. There were 15 (16%) schools that provided universal training programmes and an additional 26 (51%) offer optional training programmes for students. There were 16 (31%) schools which had an AED available on the school premises. The most common reasons for not having a universal CPR training programme is the requirement for additional class time (15/51; 29%) and that funding is unavailable for such a programme (12/51; 24%). There were three students who died from sudden cardiac arrest over the period of the past 10 years.

**Conclusion** CPR and AED training rates in London secondary schools are low. The majority of schools do not have an AED available on premises. The most common reason for not providing CPR training is the requirement for additional class time. These data highlight an opportunity to vastly improve CPR training rates in a large population. Future studies should assess programmes which are cost-effective and which do not require significant amounts of additional class time.

**Magical manoeuvre: a 5-second instructor’s intervention helps lightweight female rescuers achieve the required chest compression depth**

A Kriksciounaitiene, A Pranskunas, M Dambrauskiene, N Jasinskas, Z Dambrauskius, E Vartkaite, J Vencloviene, D Vaitkaitis
Lithuanian University of Health Sciences, Kaunas, Lithuania

**Introduction** Adequate chest compression (CC) depth is crucial for resuscitation outcomes. Lightweight rescuers, particularly women, are often unable to achieve the required 5 to 6 cm CC depth. This non-randomised cohort study investigated new strategies to improve CC performance.

**Methods** Data were prospectively collected from January 2011 to January 2012 from 336 female medical and pharmacy students undergoing CPR training at the Lithuanian University of Health Sciences. During the training process, the instructors performed a simple 5-second intervention (Andrew’s manoeuvre) with all of the rescuers in the study group. The instructor pushed 10 times on the shoulders of each trainee while she performed CCs to achieve the maximal required compression depth. Immediately after training, the participants were asked to perform a 6-minute BLS test on a manikin that was connected to a PC with SkillReporter™ System software (Laerdal, Norway); the hand positioning of the rescuer while she performed CCs to achieve the maximal required compression depth was then evaluated.

**Results**

The CC depth in the study group increased by 6.4 mm (P < 0.001) compared with the control group (52.9 vs. 46.6 mm). A regression analysis showed that Andrew’s manoeuvre increased the depth of the CCs among women by 14.87 ± (1 – 0.01 x weight) mm.

**Conclusion** Andrew’s manoeuvre during CPR training significantly improved the performance of the female rescuers and helped them achieve the CC depth required by 2010 resuscitation guidelines. It is most effective among the women with the lowest body weight.

**TRACE: a new protocol for ultrasound examination during out-of-hospital cardiac arrest**

J Calleraova1, R Skulec2, J Knor3, V Ceryny1
1Emergency Medical Service of Central Bohemian Region, Beroun, Czech Republic; 2Charles University in Prague, University Hospital Hradec Králové, Czech Republic; 3J.E. Purkinje University, Masaryk Hospital, Usti nad Labem, Czech Republic

**Introduction** Implementation of point-of-care ultrasound examination into cardiopulmonary resuscitation (CPR) may increase diagnostic accuracy for determining the cause of cardiac arrest. However, current protocols either do not reflect all causes detectable by ultrasound or are too complicated for prehospital use. Thus, we decided to construct and validate a new protocol TRACE (ThoRacic and Abdominal sonography in Cardiac arEst) for ultrasound examination during out-of-hospital cardiac arrest (OHCA).

**Methods** We designed a new protocol for ultrasound examination during OHCA to increase the success rate for the establishment of OHCA cause. The subcostal view was performed during planned rhythm check to assess the presence of cardiac tamponade and size of the right and left ventricle and inferior caval vein. Thereafter, during ongoing cardiac compressions, Morrison’s pouch and right pleural space were investigated to exclude intraperitoneal and intrapleural free fluid. The same procedure was applied on the left side of the body. Finally, the anterior thoracic view was done to exclude pneumothorax. Working diagnosis was compared with the final in-hospital diagnosis or autopsy.

**Results** We examined 40 consecutive OHCA patients. Correct cause of OHCA during CPR was recognised in 38 patients (95%). Leading causes were acute coronary syndrome (55.0%), pulmonary embolism (15.0%) and complication of chronic heart failure (10.0%). Incorrect recognition was performed in one patient with respiratory cause, originally considered as pulmonary embolism, and in another with pulmonary embolism, considered as respiratory cause. One rhythm check was sufficient to perform TRACE in 31 patients, in the other two interruptions of cardiac compressions were required. Return of spontaneous circulation was achieved in 15 (37.5%) patients, favourable neurological outcome at hospital discharge in eight (20%) patients. Specific therapy to affect the cause of OHCA was applied during OHCA in 12 (30%) patients.

**Conclusion** Implementation of the TRACE protocol to the CPR process was feasible, required minimal interruption of cardiac compressions and resulted in a high recognition rate for the cause of OHCA.
Conclusion Positional changes during simulated refractory cardiac arrest in this experimental model significantly affect resuscitability and brain perfusion. Animals subjected to shorter time in a more inclined (GROUP 60) position were more easily resuscitated; however, cerebral blood flow was better preserved in GROUP 30.

P418
Predictors of return of spontaneous circulation and survival in in-hospital cardiac arrest: a retrospective study in a single institution
JL Chua1, ZM Lin1, JH Tan1, S Surentheran1, M Haris Bin Iskander1, B Leong2
1National University of Singapore, Singapore; 2National University Hospital, Singapore

Introduction Despite several large studies concerning out-of-hospital cardiac arrests in recent years, it is not clear whether their in-hospital counterparts have benefitted from advances in resuscitation as well as post-resuscitation care.

Methods We identified all cases of in-hospital cardiac arrest (IHCA) occurring in the National University Hospital in Singapore from 1 June 2008 to 31 May 2009. Patients for which IHCA occurred but where no resuscitation was attempted were excluded. Key outcomes were classified as primary (survival to discharge) and secondary (return of spontaneous circulation). Additionally, various arrest characteristics were analysed to identify predictive factors for survival to discharge with level of significance set at \( P < 0.05 \).

Results Among 353 unique cases of IHCA analysed, 63 patients (17.8%) had a shockable rhythm (ventricular fibrillation and pulseless ventricular tachycardia) of which 17 (27.0%) survived to discharge. While 290 (82.2%) patients presented with nonshockable rhythm (asystole or pulseless electrical activity), only 32 patients (11%) survived to discharge. For patients who survived to discharge, univariate analysis showed that event location \( (P = 0.016) \), nationality \( (P = 0.035) \), paying class \( (P = 0.038) \), use of ECG monitoring \( (P = 0.048) \), initial cardiac rhythm \( (P = 0.000) \) and presence of a house officer \( (P = 0.005) \) were statistically significant. Multivariate analysis showed that patients with shockable rhythms were 2.52 times more likely to survive but other factors were not significant. For patients who attained ROSC, univariate analysis showed that time of day \( (P = 0.006) \), event location \( (P = 0.000) \) and number of adrenaline doses administered \( (P = 0.005) \) were statistically significant. Multivariate analysis showed that an arrest occurring in the ICU setting was 2.92 times more likely to attain ROSC (95% CI: 1.02 to 5.59, \( P = 0.044 \)).

Conclusion The results of this study have described some key predictive factors regarding positive outcomes in IHCA in Singapore. These are vital in understanding important features regarding IHCAs and will aid in developing policies to help improve care and survival in this group of patients.

Comparison of complications of CPR between out-of-hospital cardiac arrest and in-hospital cardiac arrest
M Seung, Y Park
Yonsei University Severance Hospital/Yonsei University College of Medicine, Seoul, South Korea

Introduction Chest compression during cardiopulmonary resuscitation (CPR) could bring out unintended complications which are mainly composed of chest injuries. The aim of this study was to assess whether there was a significant difference in the complications of CPR between out-of-hospital cardiac arrest (OHCA) and in-hospital cardiac arrest (IHCA) survivors using multidetector computed tomography (MDCT).

Methods We performed a retrospective cohort study in the emergency departments of two academic tertiary care centres from January 2009 to May 2014. We enrolled both OHCA and IHCA patients who underwent successful CPR. The enrolled patients had undergone a chest CT within 48 hours after ROSC. We evaluated the MDCT findings of the CPR-related chest injuries and compared complications between OHCA and IHCA patients.

Results A total of 148 patients were finally enrolled in this study, OHCA were 89 (60.1%) and IHCA were 59 (39.8%). The mean CPR time, both in-hospital and total, was longer in OHCA survivors. Rib fractures were...
Impact of intra-arrest fluid loading with different doses of P420

R Skulec1, A Truhlar1, R Parizkova1, Z Turek1, D Astapenko1, J Dudakova2, V Cerny3

P420
Impact of intra-arrest fluid loading with different doses of crystalloid infusion on hemodynamics in experimental cardiac arrest

Introduction Fluid loading during cardiopulmonary resuscitation for nonhypovolemic cardiac arrest remains controversial. Thus, we conducted an experimental study comparing the impact of two different doses of balanced crystalloid infusion on hemodynamics in a porcine model of ventricular fibrillation.

Methods Ventricular fibrillation was induced for 15 minutes in 19 anesthetized domestic pigs. Before induction, the animals were randomized to receive either 1,000 ml (34 ± 3 ml/kg, group A, n = 7) or 500 ml (16 ± 2 ml/kg, group B, n = 7) of balanced crystalloid solution or to undergo no fluid loading during CPR (group C, n = 5). After spontaneous circulation (ROSC) was restored, the animals were observed for 90 minutes.

Results In all groups, significant increase of intracranial pressure followed by its decrease after ROSC was observed. While in groups B (from 12 ± 2 to 18 ± 3 mmHg, P < 0.05) and C (from 13 ± 1 to 18 ± 3 mmHg, P < 0.05) it was comparable (P > 0.05), the rise of intracranial pressure in group A was significantly higher (from 12 ± 3 to 23 ± 3 mmHg, P < 0.05). Whereas coronary perfusion pressure was lower in group A than in control group C during volume loading, fluid infusion induced its mild increase in group B (group A: 12.1 ± 2.4, group B: 16.0 ± 2.6, group C: 13.6 ± 2.8 mmHg, P = 0.043). Decrease of cerebral perfusion pressure was equal in all groups. Cardiac index 10 minutes after ROSC significantly differed among all groups (group A: 8.9 ± 2.2, group B: 7.1 ± 1.3, group C: 4.9 ± 1.9/min/m², P = 0.007) and the dose of crystalloid infusion during cardiac arrest positively correlated with cardiac index increase (r = 0.815, P < 0.001).

Conclusion Fluid loading during CPR had significant impact on hemodynamics in our experimental model. While a high dose led to unintentional increase of intracranial pressure and decrease of coronary perfusion pressure, a low dose did not affect intracranial pressure and was associated with mild increase of coronary perfusion pressure during cardiac arrest.

References
prognostic impact of angiography and primary percutaneous coronary intervention (PPCI) in this patient group.

Methods A retrospective analysis using Trust electronic databases (Symphony, WardWatcher, PICIS, PRISM) of all OHCA patients admitted to our ICU over 3 consecutive years between 1 November 2011 and 31 October 2014.

Results A total of 351 patients presented to our emergency department (ED) following OHCA in this period, and of these 50% died in the ED, 37% were admitted to the ICU and 13% were admitted elsewhere. Of the 129 patients admitted to the ICU, median age was 66 (range 18 to 93), 71% were male, 68% had a shockable presenting rhythm, median ICU LOS was 3.75 (range 1 to 34 days) and ICU and hospital mortalities were 50% and 60% respectively. Eighty-nine percent (n = 48) of OHCA survivors admitted to the ICU had a shockable rhythm compared with 55% (n = 41) of nonsurvivors. Eighty-three percent (n = 45) of survivors admitted to the ICU went to the cardiac cathlab before ICU admission compared with 53% (n = 39) of nonsurvivors. Forty-three percent of survivors had PPCI compared with 26% of nonsurvivors. Eighty-one percent (n = 44) of survivors received therapeutic hypothermia compared with 62% (n = 48) of nonsurvivors.

Conclusion Over 3 consecutive years our annual case mix, ICU and hospital mortalities for OHCA patients admitted to the ICU have remained stable, while our annual pre-ICU cathlab and PPCI utilisation have risen consistently in both survivors and nonsurvivors. ICU survivors were more likely to have had a shockable rhythm, been to the cathlab, and received PPCI and TH, but all may simply reflect selection bias. Any benefit these conferred to cardiac patients may have been offset by our liberal ICU admission policy to OHCA with nonshockable rhythms. Access to 24–7 PPCI in this group may determine survival and we suggest that OHCA patients should be taken directly to regional heart attack centres.

P423

Utilisation and prognostic impact of angiography and primary percutaneous coronary intervention prior to intensive care admission for patients following out-of-hospital cardiac arrest

L Eveson, S Shrestha, M Davies, V Achan, M Peck

Flinnley Park Hospital, Flinnley, UK

Introduction Our 700-bed hospital has a 24–7 cathlab service that routinely investigates patients with indications prior to ICU admission following out-of-hospital cardiac arrest (OHCA). Our aim was to compare ICU survivors and nonsurvivors and evaluate the utilisation and prognostic impact of angiography and primary percutaneous coronary intervention (PPCI) in this patient group.

Methods A retrospective analysis using Trust electronic databases (Symphony, WardWatcher, PICIS, PRISM) of all OHCA patients admitted to our ICU over 3 consecutive years between 1 November 2011 and 31 October 2014.

Results A total of 351 patients presented to our hospital following OHCA in this period, and of these 50% died in the ED, 37% were admitted to the ICU and 13% elsewhere. Of the 129 patients admitted to the ICU, median age was 66 (range 18 to 93), 71% were male, 68% had a shockable presenting rhythm, median ICNARC score was 31 (range 10 to 66), median ICU LOS was 3.75 (range 1 to 34 days) and ICU and hospital mortality were 50% and 60% respectively. ICU survivors were more likely to have had a shockable rhythm (89 vs. 55%), been to the cathlab (83 vs. 53%), received PPCI (43 vs. 26%) and TH (82 vs. 62%) and had lower median ICNARC scores (26 vs. 35) than nonsurvivors. Over the 3 consecutive years, pre-ICU cathlab and PPCI utilisation increased annually in ICU survivors (73 vs. 86 vs. 89% and 45 vs. 54 vs. 59% respectively) and nonsurvivors (40 vs. 38 vs. 50% and 20 vs. 27 vs. 31% respectively). However, our annual ICU and hospital mortality remained unchanged (46 vs. 51 vs. 51% and 60 vs. 57 vs. 62% respectively).

Conclusion ICU survivors were more likely to have had a shockable rhythm, been to the cathlab, received PPCI and TH and been less sick than nonsurvivors, but these may simply reflect selection and other biases. Any benefit these factors did confer to cardiac patients may have been offset by our liberal ICU admission policy to OHCA with nonshockable rhythms. However, access to 24–7 PPCI may determine survival and we suggest that all OHCA patients should be taken directly to regional heart attack centres.

Targeted temperature management after cardiac arrest and fever control with an esophageal cooling device

A Hegazy, D Lapiere, E Althenayan

University of Western Ontario, London, ON, Canada

Introduction Mild hypothermia and fever control have been shown to improve neurological outcomes post cardiac arrest. Common methods to induce hypothermia include body surface cooling and intravascular cooling; however, a new approach using a catheter placed into the esophagus has recently become available.

Methods We report the first three cases of temperature control using an esophageal cooling device (ECD). The ECD was placed orally in a similar fashion to orogastric tubes. Temperature reduction was achieved by connecting the ECD to a commercially available heat exchange unit (Blanketrol II or III).

Results The first patient, a 59-year-old male (73 kg), was admitted after successful resuscitation from a protracted out-of-hospital cardiac arrest. His initial temperature was 35°C, which is within our current institutional protocol of 34 to 36°C. Several hours after arrival, his temperature slowly increased to 35.8°C despite application of a cooling blanket and ice packs to the groin and axilla. The ECD was inserted and a reduction of temperature to 34.8°C was achieved within 3 hours. The patient expired on day 3. The second patient, a 54-year-old female (95 kg), was admitted after resuscitation from an out-of-hospital PEA arrest. Despite initiating our cooling protocol with surface-cooling blankets and cold intravenous saline, she mounted a fever peaking at 38.3°C shortly after admission. After ECD insertion and confirming the external heat exchanger connection, her temperature gradually dropped to 35.7°C over a period of 4 hours. She subsequently made a favorable neurological recovery and was discharged home at day 23. The third patient, a 47-year-old male patient (86 kg) presented with an ongoing fever secondary to necrotizing pneumonia in the postoperative period after coronary artery bypass grafting. His fever was unresponsive to empiric antibiotic therapy, antipyretics, cooling blankets, and ice packs. ECD insertion resulted in a decrease in temperature from 39.5°C to 36.5°C in less than 5 hours. The patient eventually made a full recovery and was discharged home after 59 days. In all three patients, placement of the device occurred in less than 3 minutes and ease of use was reported as excellent by nursing staff and physicians.

Conclusion The ECD is a novel technology that can be used for temperature management post cardiac arrest and for fever control in critically ill patients. Despite patients mounting a febrile response, temperature control was achieved and maintained successfully. The device was reported as being easy to use, by both physicians and nurses.

Is selective nasopharyngeal brain cooling detrimental to neuroprotection?

M Kumar, L Johnson, A Goldberg, M Kashiorius, L Keenan, A Rabinstein

Mayo Clinic, Rochester, MN, USA

Introduction Clinical outcomes vary depending on the method used to induce therapeutic hypothermia following stroke or cardiac arrest. In swine, we tested the hypothesis that selective nasopharyngeal brain cooling (SNBC), in contrast to systemic hypothermia, adversely impacts cerebral perfusion.

Methods In two groups of animals (34 to 35 kg), blood flow in the right middle cerebral artery (MCA) was measured using transcranial Doppler (TCD). In group 1, SNBC was initiated using perfluorohexane aerosol (1 ml/kg/minute) and oxygen (1 l/kg/minute) through a nasopharyngeal catheter atomizer. In group 2, the animals were body surface cooled using water-circulating blankets (4°C). In both groups,

brain temperature, intracranial pressure (ICP), core temperatures and vital signs were continuously recorded. Cooling was terminated once the brain reached 32°C and the animals were allowed to passively rewarm.

Results In the SNBC group, the brain target temperature was reached in 54 ± 11 minutes. The mean ICP dropped precipitously to a nadir of −15 mmHg. TCD showed significant vasospasm in the MCA, compared with the internal carotid artery (ICA), during the entire cooling phase (Table 1). Upon termination of cooling, the brain temperature spontaneously rewarmed to core temperature in 13 ± 4 minutes. Rewarming was associated with hyperemia and elevation of ICP. In group 2, there was no cerebral vasospasm or hyperemia during cooling and rewarming respectively.

Conclusion SNBC is associated with significant vasospasm of the MCA. In addition, spontaneous and rapid rewarming of the brain, vasodilation, rapid reperfusion, and rebound elevation of ICP, all occurring minutes after termination of SNBC, are likely to be detrimental to an already ischemic brain.

Hemodynamic targets during therapeutic hypothermia after cardiac arrest: a prospective observational study

K Ameloot, J Meex, C Genbrugge, W Boer, F Jans, B Ferdinand, W Mullens, M Dupont, C Diedeyne, J Dens
ZOL Genk, Belgium

Introduction In analogy with sepsis, current postcardiac arrest (post-CA) guidelines recommend to target mean arterial pressure (MAP) above 65 mmHg and SVO₂ above 70%. This is unsupported by mortality or cerebral perfusion data. The aim of this study was to explore the associations between MAP, SVO₂, cerebral oxygenation and survival.

Methods A prospective, observational study during therapeutic hypothermia (24 hours −33°C) in 82 post-CA patients monitored with near-infrared spectroscopy.

Results Forty-three patients (52%) survived in CPR 1 to 2 until 180 days post CA. The mean MAP range associated with maximal survival was 76 to 86 mmHg (OR = 2.63, 95% CI (1.01; 6.88), P = 0.04). The mean SVO₂ range associated with maximal survival was 67 to 72% (OR = 8.23, 95% CI (2.07; 32.68), P ≤ 0.001). Presenting in nonshockable rhythms with ROSC >20 minutes in nonshockable rhythms had 19 patients with two survivors (10.5%), and 1 survivor (5.3%) in shockable rhythms had 54 patients with 18 survivors (33.3%). Time >20 minutes until ROSC in shockable rhythms had five patients with three survivors (78%, P = 0.001). Presenting in nonshockable rhythms with ROSC <20 minutes were 99 patients with all 44 survivors or families contacted up to 4 years.

Results Sixty-nine males and 38 females with a mean age of 60.2 years showed 63 dead (58%) and 44 survivors (42%). Presenting cardiac rhythm was divided into shockable (pulsless ventricular tachycardia, ventricular fibrillation) and nonshockable (pulsless electrical activity, asystole). Presenting in shockable rhythms with ROSC <20 minutes were 99 patients with 15 (71%) survivors (P = 0.001). Time >20 minutes until ROSC in shockable rhythms had five patients with three survivors (78%, P = 0.001). Presenting in nonshockable rhythms with ROSC <20 minutes were 99 patients with 15 (71%) survivors (P = 0.001). Time >20 minutes in nonshockable rhythms had 19 patients with two survivors (8%, P = 0.001). Survivors of shockable rhythms showed 19 (100%) living post TH. Fifteen survivors (79%, n = 19, P = 0.001) had CPC 1, 62 (65%) survivors (62/96, P = 0.001). Presenting in shockable rhythms with ROSC >20 minutes in nonshockable rhythms had 19 patients with two survivors (8%, P = 0.001). Survivors of shockable rhythms showed 19 (100%) living post TH. Fifteen survivors (79%, n = 19, P = 0.001) had CPC
score 1 or 2 with four survivors (21%, n = 19) having a CPC score of 3. A total of 25 survived nonshockable rhythm. Acute survival of patients with nonshockable rhythm showed 18 expired <72 hours (72%, n = 25) with long-term survival of four patients (5%, n = 74) and CPC scores of 1 or 2 (P = 0.001). Interestingly, patients with time to ROSC >20 minutes exhibiting more than one loss of sustained ROSC showed 100% mortality (P = 0.001). Patients presenting with shockable >20 minutes ROSC had overall survival of 70% (P = 0.001), but those undergoing >3 cardiac rhythm changes had 100% mortality (P = 0.001).

**Conclusion** Patients presenting with shockable rhythms undergoing TH had overall acute survival of 70% followed by long-term survival of 100% after 4 years. In contrast, patients presenting with nonshockable rhythm had long-term survival of 5%. TH is not recommended.

**P429**

**Difference in cerebral saturation during cardiopulmonary resuscitation between survivors with favorable neurological outcome and compromised neurological outcome at hospital discharge**

C Genbrugge, W Boer, I Meeu, F Jans, C Deeyne, J Dens
ZOL, Genk, Belgium; Hasselt University, Hasselt, Belgium

**Introduction** During out-of-hospital cardiac arrest (OHCA) monitoring possibilities are limited. Recently, the role of cerebral oximetry, using near-infrared spectroscopy, during ALS was investigated. In this study we determined whether the magnitude of increase in cerebral saturation (rSO2) or mean rSO2 during prehospital ALS was associated with good neurological outcome at hospital discharge (Cerebral Performance Category [CPC] 1 or 2).

**Methods** With IRB approval, we prospectively measured rSO2 during ALS in consecutive OHCA patients. One sensor of the Equanox™ 7600 (NONIN) was applied on the patient’s forehead’s right side when the medical emergency team arrived in an OHCA. ROSC was defined as ROSC >20 minutes.

**Results** We included 88 prehospital cardiac arrest patients between December 2011 and October 2014 with eight (9%) patients with CPC 1 or 2. Twenty-seven patients of the nonsurvivors had ROSC >20 minutes and one patient had CPC 3 at hospital discharge. We observed no significant difference between both groups in age (P = 0.161), time between emergency call and start of ALS (P = 0.788) and duration of basic life support performed by bystanders, general practitioners or paramedics (P = 0.649). The initial rhythm was asystole in one (12.5%) survivor and in 50 (62.5%) nonsurvivors (P = 0.009), ventricular fibrillation in six (7%) survivors and 13 (16%) nonsurvivors (P = 0.001), and pulseless electrical activity in one (12.5%) survivor and 17 (21%) nonsurvivors (P = 1.00). The cardiac arrest was witnessed in all survivors (100%) and in 49 (61%) nonsurvivors (P = 0.046). First measured rSO2 was 86% (27 to 67) in the survivor group compared with 22% (8 to 32) in the nonsurvivor group (P = 0.004). Also a significant difference was found in mean rSO2 until 1 minute before ROSC between survivors and nonsurvivors, respectively 46% (40 to 74) and 34% (22 to 42). We observed no significant difference in increase of rSO2 until 1 minute before ROSC between survivors 12.5% (5 to 21) and nonsurvivors 11% (5 to 18) (P = 0.719).

**Conclusion** We observed a significant difference in first measured rSO2, and mean rSO2, until 1 minute before ROSC between patients with good neurological outcome (CPC 1 or 2) at hospital discharge and patients with worse neurological outcome or nonsurvivors (CPC 3 or 4 or 5). However, no significant difference was observed in the increase between both groups. Larger studies are necessary to confirm these results.

**P430**

**Association between hemoglobin, cerebral oxygenation and neurologic outcome in postcardiac arrest patients**

I Meeu, K Ameloot, C Genbrugge, M Dupont, B Ferdinand, J Dens, C Deeyne
ZOL Genk, Belgium

**Introduction** The safety of a restrictive transfusion threshold of 7 g/dl applied in all critically ill patients can be questioned in postcardiac arrest (post-CA) patients since these are phenotypically clearly distinct. The aims of this study were to investigate the association between hemoglobin, cerebral oxygenation (SctO2) and outcome in post-CA patients.

**Methods** A prospective observational study in 82 post-CA patients during hypothermia in the first 24 hours of ICU stay. Hemoglobin was determined hourly together with a corresponding SctO2 by NIRS and SVO2 in patients with a pulmonary artery catheter (n = 62).

**Results** Based on 2,099 paired data, we found a strong linear relationship between hemoglobin and average SctO2 (SctO2 = 0.70 × hemoglobin + 56 (P = 20.84; P = 10^-4)). Given the previously suggested SctO2 target between 66 and 68%, hemoglobin levels below 10 g/dl generally resulted in suboptimal brain oxygenation. Forty-three patients (52%) had a good neurological outcome (CPC 1 to 3) at 180 days post CA. There was a significant association between average hemoglobin above 12.3 g/dl and good neurological outcome (OR = 2.88, 95% CI = 1.02; 8.16, P = 0.04). In a multivariate model, this association persisted after correction for comorbidities and age by the modified Charlson score (OR = 2.99, 95% CI = 1.05; 8.53, P = 0.03). This association was entirely driven by results obtained in patients with an average SVO2 below 70% (OR = 17.55, 95% CI = 1.67; 184.41, P = 0.01).

**Conclusion** There is a steep linear relationship between hemoglobin and SctO2 in post-CA patients with hemoglobin levels below 10 g/dl generally resulting in cerebral desaturation. Average hemoglobin below 12.3 g/dl was independently associated with worse neurological outcome 180 days post CA. An interventional trial is necessary to investigate whether maintaining higher hemoglobin would improve outcome.

**P431**

**Somatosensory evoked high-frequency oscillations and prognostication after cardiac arrest**

C Endisch, C Storm, CJ Ploner, C Leithner
Charité Universitätsmedizin Berlin, Germany

**Introduction** Electrical median nerve stimulation elicits a burst of high-frequency oscillations (HFOs) superimposing on the cortical short-latency potential. Digital filtering of somatosensory evoked potentials (SSEPs) enables non-invasive analysis of these HFOs. The late HFO component following the cortical N2O peak is ascribed to spiking activity of cortical neurons.

**Methods** We retrospectively studied late HFO components of median nerve SSEPs obtained 24 hours to 4 days after cardiac arrest in patients treated with mild hypothermia (33°C for 24 hours). Cortical average recordings were digitally filtered at 450 to 750 Hz and noise-corrected maximum peak-to-peak amplitudes of the cortical late HFO bursts determined. Outcome upon ICU discharge was dichotomized according to the Cerebral Performance Category (CPC) scale. CPC 1 to 3 was classified as good outcome, CPC 4 to 5 (unresponsive wakefulness syndrome and death) as poor outcome.

**Results** Of 307 consecutive patients, 153 (50%) achieved good outcome (CPC 1 to 3) and 154 (50%) had poor outcome. Late HFO bursts were present in 102 (33%) recordings. Among patients with late HFO amplitudes above 0.1 μV, 26 had CPC 1 to 3, none had CPC 4 and eight died. Case review indicated causes of death other than hypoxic encephalopathy in all patients who died despite HFO amplitudes above 0.1 μV.

**Conclusion** We found cortical late HFO bursts, obtained by digital filtering of standard SSEP recordings, in a significant proportion of patients after cardiac arrest treated with mild hypothermia. Our data indicate that the presence of late HFO bursts with amplitudes above 0.1 μV may confirm absence of severe hypoxic encephalopathy early after cardiac arrest with high specificity.

**P432**

**One-size-fits-all or patient-tailored hemodynamic targets in post-cardiac arrest patients: an observational near-infrared spectroscopy study on cerebral autoregulation**

C Genbrugge, K Ameloot, I Meeu, W Boer, F Jans, W Mullens, M Dupont, B Ferdinand, J Dens, C Deeyne
ZOL Genk, Belgium

**Introduction** A subgroup of post-CA patients with disturbed cerebral autoregulation might benefit from higher mean arterial pressures
(MAPs). We aimed to (1) investigate whether patients with disturbed autoregulation have a worse prognosis, (2) phenotype these patients, (3) define an individual optimal MAP and (4) investigate whether time under this individual optimal MAP is associated with outcome.

**Methods** A prospective observational study in 51 post-CA patients monitored with near-infrared spectroscopy.

**Results** (1) In multivariate analysis, patients with preserved autoregulation (33.65%) had a significantly higher 180-day survival rate (OR = 4.62, 95% CI (1.06, 20.06), P = 0.04). (2) Phenotypically, a higher proportion of patients with disturbed autoregulation had pre-CA hypertension (31 ± 47 vs. 65 ± 49%, P = 0.02) suggesting that right shifting of autoregulation is caused by chronic adaptation of cerebral blood flow to higher blood pressures. Based on an index of autoregulation (COX), the average COX-predicted optimal MAP was 85 mmHg in patients with preserved and 100 mmHg in patients with disturbed autoregulation. (3) An individual optimal MAP could be determined in 33/51 patients. (4) The time under the individual optimal MAP was negatively associated with survival (OR = 0.97, 95% CI (0.96, 0.99), P = 0.02). The time under previously proposed fixed targets (65, 70, 75, 80 mmHg) was not associated with a differential survival rate.

**Conclusion** Cerebral autoregulation was shown to be disturbed in 35% of post-CA patients of which a majority had pre-CA hypertension. Disturbed cerebral autoregulation within the first 24 hours after CA is associated with a worse outcome. In contrast to uniform MAP goals, the time spent under a patient-tailored optimal MAP, based on an index of autoregulation, was negatively associated with survival.

**P433** Response of regional oxygen saturation technologies during hypoxia

UB Borg, AM Neiteimbach
Coviden, Boulder, CO, USA

**Introduction** The purpose of this study was to determine the rate and magnitude of response to hypoxia for three different regional oxygen saturation (rSO2) devices. rSO2 technologies are focused on absolute accuracy without consideration of response characteristics. Current rSO2 technologies assume that the oxygen saturation is a fixed ratio of arterial and venous blood. Cerebral arteries have an oxygenation-related vasoactivity that may change the arterial/venous ratio during hypoxia. Thus, absolute rSO2 accuracy may be less important compared with sensitivity to changes in cerebral rSO2.

**Methods** Ten subjects completed the study and are included in the analysis. One INVOS sensor (SAF6-SM) was placed on the left side and one Equanox (8000CA) or Foresight (1 July 2007 or 1 July 2005) sensor (alternated between subjects) was placed on the right side of the forehead for bilateral monitoring. Desaturation was induced by titrating from room air to achieve a plateau of 70% arterial oxygen saturation (SpO2). Resaturation was induced by rapid change in FiO2 to 1.0. After 5 minutes of SpO2 100%, the process was repeated by desaturation to SpO2 70% and rapid return to SpO2 100%. Cerebral and pulse oximetry data were recorded during the study and the time of each FiO2 change and plateau was recorded. rSO2 levels at 10, 20, 40, 60 and 80% of the total SpO2 response were calculated for each device to assess the rate of rSO2 change. The rate of rSO2 change in seconds and total rSO2 change were compared.

**Results** The rate of rSO2 change during desaturation was similar for all devices with an average slope factor of 0.17 for Foresight, 0.16 for Equanox and 0.21 for INVOS. The rate of rSO2 change in seconds during resaturation from SaO2 70% to SaO2 100% was significantly faster for INVOS (42 ± 16) compared with Foresight (57 ± 20) (P < 0.05). There was significant difference in total rSO2 change between INVOS (23 ± 4%) and Equanox (15 ± 4%) during desaturation and resaturation (P < 0.005) and between INVOS compared with Foresight (20 ± 5%) (P < 0.05).

**Conclusion** All rSO2 devices followed the SpO2 slope during desaturation as expected. The differences between the devices in terms of total rSO2 change reached statistical significance. There were also significant differences in the rate of rSO2 change in seconds between INVOS and Foresight during resaturation. The rate of absolute change in seconds and the magnitude of absolute change may result in better resolution to detect physiological changes. Clinical studies are required to elucidate the clinical relevance of the differences.

**P434** Use of bispectral index EEG monitoring for a fast and reliable detection of epileptic activity in postcardiac arrest patients

J Haesen1, L Desteghe1, I Meex1, C Genbrugge1, J Demeester2, J Dans1, L Ermoni1, C De Deyne1
1Universiteit Hasselt, Belgium; 2Ziekenhuis Oost-Limburg, Genk, Belgium

**Introduction** Assessment of prognosis in postcardiac arrest (post-CA) patients became very challenging since the introduction of therapeutic hypothermia (TH). Continuous EEG monitoring has been proposed to improve prognostication; however, its use is limited due to difficulties in ready interpretation. Thus emerges the need for a simple EEG montage. The bispectral index (BIS) monitor is a simplified EEG system, mainly calculating an index ranging from 0 (isoelectric EEG) to 100 (full consciousness) to provide information on hypnotic depth of anaesthesia. The aim of the study was to validate the accuracy of simplified EEG monitoring in a CA setting.

**Methods** BIS monitoring (BIS VISTATM) was applied to collect frontaltemporal data in TH-treated CA patients. A standard 19-channel EEG was performed after return to normothermia. Afterwards, small EEG frames coincident with the time of full EEG registration were extracted from the BIS monitor. We asked two neurophysiologists to indicate the presence of status epilepticus (SE), cerebral inactivity (CI), burst suppression (BS), periodic epileptiform discharges (PEDs) or a diffuse slowing pattern (DS). In addition, these samples were analysed by two inexperienced physicians, who were asked to indicate the presence of SE.

**Results** Thirty-four simplified EEG samples were analysed. According to standard EEG, 11 patients showed a DS pattern, three had CI, six showed BS, four showed PEDs and 10 had an SE. Neurophysiologists interpreted all samples with a high accuracy. Mean sensitivity was 82.12% and mean specificity was 91.88%. Only one SE was missed by one neurophysiologist. Unfortunately, only one PED was confirmed by both neurophysiologists. Interobserver reliability was high (κ = 0.843). High correlations were found for the comparison of full and simplified EEG for both neurophysiologists (r = 0.809). Further, the two inexperienced physicians identified SE with a sensitivity of 85% and specificity of 98%.

**Conclusion** Simplified EEG monitoring, using BIS, resulted in high accuracy of a simple classification system in post-CA patients. Not only neurophysiologists, but also treating physicians were capable to identify SE, which may play an important role in the early detection of SE. We suggest using BIS as a screening tool in post-CA patients to save valuable time in the detection of SE, without replacing the need for full EEG monitoring for confirmation.

**P435** Differences in cerebral saturation measured during prehospital advanced life support, between patients with presumed cardiac origin and noncardiac origin of cardiac arrest

C Genbrugge1, W Boer1, K Anseewu1, I Meex1, F Jans1, J Dans1, C de Deyne1
1ZOL, Genk, Belgium; 2ZNA Stuivenberg, Belgium; 3Hasselt University, Hasselt, Belgium

**Introduction** During out-of-hospital cardiac arrest (OHCA) cerebral saturation may provide relevant information on cerebral oxygenation. In this study we examined the time course in cerebral saturation (rSO2) during prehospital ALS comparing patients with a presumed cardiac origin (survivor = Sc, nonsurvivor = NSc) of arrest and noncardiac origin (survivor = Sn, nonsurvivor = NSn) of arrest.

**Methods** With IRB approval, we prospectively measured rSO2, from the start of ALS in consecutive OHCA patients. One sensor (Equanox™ 7600; Nonin) was applied on the patient’s forehead’s right side when
the medical emergency team arrived at the OHCA setting. ROSC was defined as ROSC >20 minutes. Retrospectively, included patients were divided into two groups with respect to their presumed origin of arrest.

**Results** Between December 2011 and October 2014, 113 OHCA patients were included. We observed a significant difference in asystole and VF as initial rhythm between NSc and NSnc, respectively (P = 0.035 and P = 0.001). In both groups of NS, duration of ALS was significant longer compared with the two Sc groups (P = 0.001 in both comparisons). We observed no significant difference in first measured rSO2, mean rSO2, until 1 minute before ROSC and increase in rSO2, until 1 minute before ROSC (respectively P = 0.123, P = 0.501, P = 0.265) between Sc and Snc. However, when we compare the nonsurvivors of cardiac with noncardiac origin, we observed a significant difference in mean rSO2 until 1 minute before ROSC, 35% (27 to 44) in the NSc group and 27 (21 to 34) in the NSnc group (P = 0.026). First measured rSO2 was 24.5% (13 to 34) in the NSc group and 14 (4 to 28) in the NSnc group (P = 0.069) trending to be significantly different. No significant difference was observed in increase until 1 minute before ROSC between both groups of NS (P = 0.920). Significant differences was observed in mean rSO2 until 1 minute before ROSC and increase in rSO2 between Sc and NSnc (P = 0.033; P < 0.001) and between Sc and NSc (P = 0.001; P < 0.001).

**Conclusion** We can conclude that NSc have a significant higher mean rSO2, which trend to have a significant difference in first measured rSO2 compared with NSnc. However, no significant difference was observed between Sc and Snc.

**Prognostic value of neuron-specific enolase after cardiac arrest and targeted temperature management**

K Strenberger, C Leithner, CJ Ploner, C Storm
Charité Universitätsmedizin, Berlin, Germany

**Introduction** The serum concentration of neuron-specific enolase (NSE) has been established as a highly specific predictor of poor outcome after cardiac arrest. Recent studies have indicated that patients treated with targeted temperature management at 33°C for 24 hours may have good outcome despite NSE serum concentrations considerably higher than the cutoff established for normothermic patients. The threshold above which survival with good outcome becomes very unlikely, its positive predictive value and sensitivity for prediction of poor outcome have not been established in this patient group. Furthermore, a threshold below which hypoxic encephalopathy may be largely excluded has not been determined.

**Methods** From 2006 through 2014 we prospectively included in-hospital and out-of-hospital cardiac arrest patients treated with targeted temperature management at 33°C for 24 hours. The NSE serum concentration was determined 3 days after cardiac arrest and the outcome was assessed according to the Cerebral Performance Category (CPC) upon ICU discharge. CPC 1 to 3 was defined as good outcome and CPC 4 to 5 as poor outcome. Individual case review was performed in patients with good outcome despite very high NSE serum concentration and in patients with poor outcome despite very low NSE serum concentration.

**Results** Of 601 included patients, 309 (51%) had good outcome. An NSE serum concentration threshold of 90 μg/l predicted poor outcome with a positive predictive value of 0.98 and a sensitivity of 0.51. Three patients survived with good outcome despite an NSE serum concentration >90 μg/l. In two of these patients NSE elevations had been documented prior to cardiac arrest. One patient had a neuroendocrine tumor of the pancreas, the other patient suffered from encephalitis of unknown etiology and an osteomyelitis. Potential confounders in the third patient were an ovarian carcinoma, the use of an intra-aortic balloon pump and blood transfusions shortly after cardiac arrest. Only 16 of 205 patients with NSE <17 μg/l had poor outcome, the majority of these patients died from causes other than hypoxic encephalopathy.

**Conclusion** In patients with cardiac arrest and targeted temperature management at 33°C, an NSE serum concentration of 90 μg/l strongly indicates poor outcome. NSE producing tumors, acute brain diseases, severe hematologic diseases, use of an intra-aortic balloon pump and blood transfusions need to be considered as potential confounders. An NSE serum concentration of <17 μg/l largely excludes hypoxic encephalopathy incompatible with re-wakening.
frequently suffered cardiogenic shock, had more organ dysfunctions and died more frequently, respectively, with hospital mortality of 79.5% versus 29.1%, P < 0.001; see also Figure 1. Conclusion. In patients hospitalized for acute heart failure, both prehospital and postadmission resuscitated cardiac arrest is a severe complication associated with significantly morbidity and mortality.

Outcome of cardiopulmonary resuscitation in cancer patients in an Indian tertiary cancer center
SN Myatra, N Prabhu, JV Divatia
Tata Memorial Hospital, Mumbai, India

Introduction Cardiopulmonary resuscitation (CPR) after cardiac arrest in cancer patients is often discouraged as it is associated with poor outcome. In our 700-bed tertiary cancer hospital in Mumbai, India, the ICU runs an in-hospital cardiac arrest team (CAT). We reviewed our data to determine outcome from CPR, identify factors associated with improved outcomes and justify the presence of a CAT in our cancer hospital.

Methods All in-hospital patients from November 2012 to November 2014 (2-year period) with unanticipated cardiorespiratory arrests were included. Data were recorded prospectively using the Utstein template. Only patients with cardiac arrest rhythms were included. Patients with anticipated progression towards arrest, those with seizures, hypotension without dysrhythmias or other medical emergencies were excluded. The outcomes studied were return of spontaneous circulation (ROSC) and survival on hospital discharge (SOHD). Binary logistic regression analysis was performed to determine factors associated with ROSC and SOHD.

Results One hundred and ninety-three patients (110 males, 83 females, mean age 48.2 ± 18.3 years) were studied. The mean time interval between collapse and onset of resuscitation was 2.3 ± 2.1 minutes. A total of 65.3% arrests were witnessed. Sustained ROSC occurred in 36.8% patients and the SOHD was 24.9%. The initial rhythm recorded during CPR was asystole in 133 patients, pulseless electrical activity in 21 patients and ventricular fibrillation/tachycardia (VF/VT) in 39 patients. SOHD for these rhythms was 8.3%, 33.3% and 76.9%, respectively. On univariate analysis, type of rhythm, witnessed arrests and time to resuscitation were associated with sustained ROSC and SOHD. On multivariate analysis, only type of rhythm, VF/VT (P = 0.000) and PEA (P = 0.017), were significantly associated with SOHD, while witnessed arrest and time to resusciation were not.

Conclusion Sustained ROSC occurred in 36.8% patients and the SOHD was 24.9%. A reduced response time, witnessed arrest and type of rhythm are associated with ROSC and improved SOHD. The type of rhythm was independently associated with SOHD, with VF/VT and PEA having improved survival while asystolic patients had a poor outcome. These considerations justify the presence of a CAT in our cancer hospital.

Outcome after CPR: when we cannot save lives, we can save organs
C Caestecker, J Froyman, P Lormans, W Stockman
AZ Delta, Roeselare, Belgium

Introduction Patients resuscitated after cardiac arrest (CA) who suffer bad neurologic outcome or become brain dead might become organ donors (OD) when well managed and identified. We report on the cohort of patients resuscitated after in-hospital or out-of-hospital CA becoming OD in a tertiary community hospital with an intensive donor identification program.

Methods Data from our 28-bed mixed medical/surgical adult ICU in a 900-bed tertiary hospital were analyzed from 2010 to 2014.

Results Our ICU admitted 2,320 patients/year. Overall ICU mortality in this period was 7.4%. A summary of the results is presented in Table 1. Of the 219 patients admitted after CA, 21 (10%) became OD. This resulted in 55 successfully transplanted organs (28 kidneys, 17 livers, seven lung pairs, three hearts). Of note, good outcome (CPC 1 and 2) was achieved in 55 patients (25%).

Total 68 21 (31%) 11/10 219

Conclusion Ten percent of patients resuscitated after CA and admitted to the ICU become OD, consisting of up to 31% of the total number of OD in our center. Patients resuscitated after CA who suffer severe irreversible brain damage or are brain dead can thus substantially expand the donor pool. This justifies extensive resuscitation efforts, if not to save lives, then to save organs. This might be reassuring for families, staff and the community.

Effect of alcohol in blood on neurological outcome and survival of patients with combination of polytrauma and head injury
S Pristovnik1, M Strnad2, V Vujanovich1, T Pelcl1, V Borovnik-Lesjak1
1 Health Center Dr. Adolf Drolc, Maribor, Slovenia; 2 Medical Faculty Maribor, Slovenia

Introduction The association between blood alcohol level (BAL) on mortality and neurologic outcome in patients with polytrauma and head injury is not clear and the data in the literature are sometimes conflicting. Some studies suggest a possible neuroprotective effect of alcohol and increased survival while others show the opposite. The rationale for this study was to investigate whether BAL has any impact on presentation, neurologic outcome and survival in patients with combination of polytrauma and head injury.

Methods This is a retrospective study of 43 polytraumatized patients with head injury who were intubated and treated by the prehospital unit and transported to the trauma center. Patients were grouped according to their BAL into BAL+ (>0.5 mg/l) and BAL− (<0.5 mg/l). Inclusion criteria were age ≥18, Injury Severity Score ≥16 and head Abbreviated Injury Scale (AIS) ≥3. Physiological parameters and outcome with respect to survival to hospital discharge (STHD) and functional outcomes were analyzed. Severity of injuries was measured using the Trauma–Injury Severity Score (TRISS) and head injury using AIS. Functional outcome was measured using the Glasgow Outcome Scale (GOS), Cerebral Performance Category (CPC) and Glasgow Coma...

Introduction

Cerebral ischemia (CeI) is a major complicating event after acute brain injury (ABI) in which endothelial dysfunction is a key player.

Methods

We studied cellular markers of endothelial dysfunction and peripheral reactive hyperemia index (RHI) in 26 patients with ABI at admission and after 6 and 12 days, and compared these with healthy volunteers (n = 15). Cel was determined clinically or using computer tomography.

Results

In patients with ABI, RHI at admission was significantly reduced compared with healthy subjects (P = 0.003), coinciding with a decrease in circulating endothelial progenitor cells (EPC) (P = 0.002) (Table 1). The RHI recovered in eight patients without development of Cel (Figure 1, black), but failed to fully recover by day 12 in three out of four patients that developed Cel (Figure 1, red). Despite recovery of the RHI within 12 days in these patients (P = 0.003), the EPC count remained significantly lower after 12 days in patients with ABI (P = 0.022) (Table 1). CD31+ T cells and endothelial microparticles were not different between controls and patients. No differences were noted in cellular markers of endothelial dysfunction in patients developing Cel and those not.

Conclusion

Patients with ABI exhibit impaired microvascular endothelial function measured as RHI and a decreased circulating level of EPC.

Introduction

Since most patients with acute brain injury are treated head-up at 30 to 45°, there can be a height difference of up to 15 cm between the heart and the ear canal. This causes a difference between mathematical CPP and true CPP of up to 11 mmHg depending on the zero reference level used and the body length of the patient (Figure 1). We conducted a survey to analyze the current practice on CPP targets and zero reference levels in different ICUs.

Methods

Neuro-ICU physicians were invited to participate in a survey on ICP and CPP targets and the level of measurement.

Results

The results of 30 centers are summarized in Table 1. Most centers (83.3%) use head-up elevation of 30 to 45° and consider an ICP of 20 mmHg as the threshold to start treating ICP (80%). More variation is noted in minimal and maximal CPP threshold. All centers measure ICP at the ear canal. Twenty-seven centers (90%) measure MAP at the heart, three centers measure MAP at the ear canal. These three centers use >50, 60 and 65 mmHg as minimal CPP and raise the bed to 30 to 45°. The two centers using minimal CPP >60 mmHg do not apply an upper limit.

Conclusion

Considering the influence of position on CPP, the variations among centers and the narrow range of CPP thresholds, future studies and guidelines should describe where MAP is measured. Alternatively, we propose a new formula for CPP: true CPP = MAP(heart) – ICP(ear) – height difference (heart to ear canal (cm)) × 0.73.

Comparison of 15Oxygen positron emission tomography and near-infrared spectroscopy for measurement of cerebral physiology
J Simpson1, N Sudhakar1, H Hare1, J Donnelly1, X Liu1, F Aigbirhio1, T Fryer1, G Stocks-Gee1, P Smielewski1, D Bulte1, J Coles1
1University of Cambridge, UK; 2University of Oxford, UK

Introduction The gold standard technique for imaging cerebral blood flow (CBF), and metabolism is 15Oxygen positron emission tomography (15O PET). Continuous near-infrared spectroscopy (NIRS) has been used to assess adequacy of cerebral oxygenation following stroke, traumatic brain injury and subarachnoid haemorrhage [1], and measurements have been compared with jugular oxygen saturation. In this study we compared NIRS with 15O PET within healthy volunteers.

Methods Fifteen healthy subjects were recruited (12 male, average age 38 years); PET precluded females of reproductive age. Steady-state 15O PET with arterial sampling was performed to measure CBF, cerebral metabolic rate of oxygen (CMRO2), oxygen extraction ratio (OEF) and PET with arterial sampling was performed to measure CBF, cerebral blood volume (CBV) [2]. Simultaneously, NIRS data were collected using a Hamamatsu NIRS 200 with sensors on either side of the forehead. NIRS OEF was calculated from tissue oxygen saturation, SaO2, and an assumed arterial/venous blood volume ratio of 30:70 [3].

Results The frontal region 15O PET CBF, CMRO2, OEF and CBV were mean (SD) 44.9 (10) ml/100 ml/minute, 158.7 (24.7) μmol/100 ml/minute, 45.8 (7.3)% and 2.8 (0.8) ml respectively, and there was no relationship between NIRS and 15O PET (Figure 1).

Conclusion We found no relationship between NIRS and baseline physiology as determined by 15O PET. Further studies should assess the dynamic response of NIRS to a measured change in physiology in patients. Further confines of NIRS include its limited and focal brain coverage.

Evaluation of infection risk and antibiotic exposure in traumatic brain injury patients treated with therapeutic normothermia
J DeGrote1, B Heathier1, J Jancok1
Hennepin County Medical Center, Minneapolis, MN, USA

Introduction The purpose of this study is to assess the rate of confirmed infections, antibiotic exposure, and monitoring practices with normothermia protocol utilization for traumatic brain injury patients. Treatment and prevention of fever is a focus of therapy for patients with severe neurological injury as fever has been identified as an independent risk factor for morbidity and mortality [1].

Methods The retrospective chart review analyzed outcomes of maintaining normothermia at 36.5°C versus a similar population without temperature control as a standard of care in patients admitted with traumatic brain injuries defined as a Glasgow Coma Score < 8 upon admission. Patients included were 18 to 59 years of age and were mechanically ventilated with intracranial pressure monitoring for greater than 72 hours. The primary outcome evaluated was the number of patients treated for confirmed infections. Secondary outcomes included the antibiotic length of therapy (LOT), antibiotic days of therapy (DOT), number of cultures, and ICU and hospital length of stay (LOS). DOT was defined as the sum of days on which each antibacterial drug was administered.

Results A total of 23 patients treated with normothermia and 119 patients in the control group were evaluated between January 2009 and September 2014. The number of patients treated for confirmed infections was similar between groups (normothermia: 73.9%, control: 80%, P = 0.803). Empiric antibiotic therapy was more commonly utilized in the normothermia group at 34% versus 20.5% (P = 0.173). Antibiotic LOT and DOT were 13.8 versus 10.8 days (P = 0.157) and 18.3 versus 16.2 days (P = 0.573) in the normothermia versus control groups, respectively. Total culture rate was lower in the normothermia group with 13.2 versus 8.78 (P = 0.0002) cultures per patient. No significant difference in hospital LOS (normothermia: 23 days, control: 18 days, P = 0.158) or ICU LOS (normothermia: 17 days, control: 15 days, P = 0.185) was demonstrated.

Conclusion Rates of confirmed infections and number of antibiotic days were similar between the normothermia and control groups, suggesting that normothermia does not increase infection risk. However, the number of cultures obtained in the control group was significantly greater than the normothermia group with a trend toward increased empiric antibiotic use.

Effect of osmotherapy with mannitol or hypertonic saline on cerebral oxygenation and metabolism in patients with intracranial hypertension after severe brain injury
T Suys1, H Quintard1, C Patet1, M Oddo1
Lausanne University Hospital, Lausanne, Switzerland

Introduction Osmotherapy with mannitol (Man) or hypertonic saline (HTS) is currently used to treat elevated intracranial pressure after severe acute brain injury (sABI); however, their effect on cerebral oxygenation and metabolism has not been extensively evaluated.

Methods A retrospective analysis of a cohort of patients with sABI after traumatic brain injury (TBI) and subarachnoid hemorrhage (SAH) monitored with cerebral microdialysis (CMD), brain oxygen (PbtO2) and ICP, results were compared with Man (20%, 0.5 g/kg) or HTS (7.5%, 100 ml, 10% mannitol and 30% hypertonic solute) administered within 20 minutes, and each patient's individual response to intervention was analyzed up to 120 minutes following infusion. Only episodes where no other hypertonic solute was administered within 2 hours before or after treatment were selected. Variables analyzed included CMD lactate, pyruvate, glucose, glutamate, lactate/pyruvate ratio, and main brain physiologic variables ICP, PbtO2, CPP. Analysis was conducted using mixed-effects multilevel regression.

Results Sixty-four treatments (32 HTS, 32 Man) were studied among 26 patients (19 TBI, seven SAH; age 42 ± 17 years, time from injury to treatment 2.6 ± 1.9 days). Man and HTS effectively decreased ICP (coefficient = −2.5 mmHg, 95% CI = −3.2 to −1.8 mmHg and −2.9 (−3.8 to −2.0) respectively; both P < 0.0001). No significant difference was found in CMD lactate, pyruvate, glucose and PbtO2 after HTS or Man treatment. CMD glutamate decreased significantly after Man (−0.73 (−1.41 to −0.052); P < 0.05), but not after HTS.

Conclusion Osmotherapy with Man and HTS treatment had no effect on cerebral oxygenation and metabolism. Man, but not HTS, favorably reduced brain glutamate. These findings support further investigation to test the value of alternative osmotic agents (such as hypertonic lactate) that may reduce ICP and at the same time improve cerebral metabolism after sABI.

P448  Neuroenergetic response to prolonged cerebral glucose depletion after severe brain injury and the role of lactate
C. Patet1, H. Quintard1, T. Syy2, L. Pellerin3, P. Magistretti1, M. Oddo1, 1CHUV – Lausanne University Hospital, Lausanne, Switzerland; 2University of Lausanne, Switzerland; 3Brain Mind Institute, Lausanne, Switzerland

Introduction In patients with acute brain injury (ABI), increased cerebral energy demand is frequent, potentially leading to cerebral glucose depletion (GD) and poor outcome. In this setting, lactate may act as supplemental fuel. We examined dynamics of cerebral lactate supply during prolonged GD in ABI.

Methods We retrospectively analyzed severe ABI (18 TBI, eight SAH) monitored with brain oxygen and cerebral microdialysis (CMD) to measure hourly levels of cerebral extracellular glucose, lactate, pyruvate and lactate/pyruvate ratio (LPR). Variations of CMD variables were analyzed as a function of GD (defined as spontaneous decreases of CMD glucose from normal to low (<1.0 mM), at least 2 hours) and increased cerebral energy demand (LPR >25).

Results During GD (60 episodes; 26 patients), we found an increase of CMD lactate (4 ± 2.3 vs. 5.4 ± 2.9 mM) and LPR (27 ± 6 vs. 35 ± 9; all P < 0.005) while brain oxygen and blood lactate remained normal. Dynamics of lactate and glucose supply were studied by analyzing the relationship between blood and CMD samples. No correlation between blood and brain lactate was found when brain glucose and LPR were normal (r = −0.12, P = 0.48; Figure 1), while this correlation became linear during GD, progressively rising to r = 0.53 (P < 0.0001) when energy demand increased, suggesting increased cerebral lactate availability. The correlation between blood and brain lactate changed in the opposite direction, decreasing from r = 0.78 to 0.37 (P < 0.0001) during GD and at LPR >25.

Conclusion Energy dysfunction is associated with increased supply of nonhypoxic cerebral lactate. Our data suggest lactate may act as an alternative substrate after ABI when availability of cerebral glucose is reduced.

Figure 1 (abstract P448). Correlations between blood and brain lactate.

P449  Correlation between intracranial pressure and pulsatility index measured by transcranial Doppler in children with severe trauma brain injury
H. Bouguetof, M. Negadi, K. El Halimi, D. Boumendil, Z. Chentouf, M. Mentouri
University Ahmed Benbella Oran 1, Oran, Algeria

Introduction This study was designed to see whether there is a correlation between the transcranial Doppler (TCD) parameters and the CPP and intracranial pressure (ICP) monitoring during the cerebral hemodynamic changes and to evaluate ICP indirectly by TCD.

Methods A prospective and descriptive study conducted in our PICU from June 2011 to December 2013. We investigated 51 children with severe trauma brain injury (TBI). The TCD measurements were routinely performed bilaterally on the middle cerebral artery parallel to the ICP registration. The ICP and CPP data were correlated to PI and the correlation coefficient calculated. To control the linear correlation, the residuals were tested for normal distribution around the regression line.

Results ICP registrations were made parallel with all TCD measurements in 51 patients. Intracranial pressure monitoring was inserted within the first 3 hours after trauma and there was no complication (infections, intracranial hemorrhage, or technical failure) related to invasive ICP monitoring. Increased ICP was noted upon transducer insertion in 38 children with male prevalence (10 girls, 28 boys). Median GCS was 6, indicating the magnitude of injury in this group of patients. The overall results of the 38 patients showed a strong correlation between the ICP and PI during the outbursts of ICP with a correlation coefficient of r = 0.89 (ICP > 20 mmHg) and r = 0.90 (ICP < 20 mmHg). The relation between ICP and PI was estimated by the linear regression equation: ICP = 22.299 × PI – 10.705 (ICP > 20 mmHg) and ICP = 38.592 × PI – 16.972 (ICP < 20 mmHg). The CPP and PI were correlated significantly during the changes in intracranial pressure. However, a better correlation was found when ICP > 20 mmHg and CPP < 50 mmHg (PI was 2.4 ± 0.89 when CPP was 35.96 ± 4.48 with a correlation coefficient of Pearson r = 0.80) than when ICP < 20 mmHg and CPP > 50 mmHg (PI was 0.78 ± 0.14 when CPP was 57.11 ± 9.62 with a correlation coefficient of Pearson r = 0.76).

Conclusion The absolute value of the PI is a reliable noninvasive indicator of ICP in pediatric severe TBI. A strong correlation between PI and ICP was demonstrated. Therefore, PI may be of guiding value in the invasive ICP placement decision in the neurointensive care patient when ICP monitoring is not systematically performed. In particular, ICP monitoring remains as grade C in the latest guidelines of management of STBI in children published in 2012.

P450  Bispectral index as a predictor of unsalvageable traumatic brain injury
S. Mahmoud
Specialist Anesthesia, Doha, Qatar

Introduction The aim was to evaluate the accuracy of bispectral index (BIS) monitoring for the diagnosis of brain death in severely comatose patients. We aimed to determine the utility of the BIS as a tool for clinical evaluation of the moment of brain death.

Methods A prospective observational study with waiver of consent was conducted in the trauma ICU for 2 years from October 2012 to September 2014. Monitoring of BIS occurred during patient stay in the ICU. Population: 62 severely comatose patients (Glasgow Coma Score less than 6) admitted to the ICU mainly because of intracerebral hemorrhage, or technical failure) related to invasive ICP monitoring. Increased ICP was noted upon transducer insertion in 38 children with male prevalence (10 girls, 28 boys). Median GCS was 6, indicating the magnitude of injury in this group of patients. The overall results of the 38 patients showed a strong correlation between the ICP and PI during the outbursts of ICP with a correlation coefficient of r = 0.89 (ICP > 20 mmHg) and r = 0.90 (ICP < 20 mmHg). The relation between ICP and PI was estimated by the linear regression equation: ICP = 22.299 × PI – 10.705 (ICP > 20 mmHg) and ICP = 38.592 × PI – 16.972 (ICP < 20 mmHg). The CPP and PI were correlated significantly during the changes in intracranial pressure. However, a better correlation was found when ICP > 20 mmHg and CPP < 50 mmHg (PI was 2.4 ± 0.89 when CPP was 35.96 ± 4.48 with a correlation coefficient of Pearson r = 0.80) than when ICP < 20 mmHg and CPP > 50 mmHg (PI was 0.78 ± 0.14 when CPP was 57.11 ± 9.62 with a correlation coefficient of Pearson r = 0.76).

Conclusion The absolute value of the PI is a reliable noninvasive indicator of ICP in pediatric severe TBI. A strong correlation between PI and ICP was demonstrated. Therefore, PI may be of guiding value in the invasive ICP placement decision in the neurointensive care patient when ICP monitoring is not systematically performed. In particular, ICP monitoring remains as grade C in the latest guidelines of management of STBI in children published in 2012.

Reference
Results Optimal CPP is probably patient, time, and pathology specific and related to cerebral autoregulation status. The fact that optimal CPP and autoregulation status varies between individual patients and over time makes it an attractive bedside tool to serve as a (simplified) monitoring tool to investigate the use of autoregulation (PRx) status to fine tune or feedback clinical treatments in individual sedated TBI patients (optimal CPP concept) [1]. Evidence is emerging for the role of other monitors (representing local metabolism, oxygen supply/use, perfusion, neuronal functioning) that enable the intensivist to employ an individualized multimodality monitoring approach in TBI [2].

Conclusion The management of TBI is likely to become increasingly based on a more comprehensive monitoring and management approach rather than relying on absolute numbers of ICP and CPP in isolation. This will allow individual optimization of perfusion and therefore of oxygen and energy substrate delivery. We await further robust, high-quality evidence to support the benefits of using more sophisticated monitoring tools like the autoregulation-guided CPP concept during the ICU management of TBI. For the near future, more important is a greater understanding of the underlying pathophysiology.

F, female; M, male. GCS, Glasgow Coma Scale: A, at admission to ICU; B, at initiation of AS therapy; C, outcome value. CRS: D, value on day 1; E, value on day 6; F, value on day 10; G, value on day 14. Complications observed: H, low platelet; J, ALT increase by twofold; K, BUN increase by twofold; L, AST increase by twofold; M, convulsion.
the ongoing Pan-Canadian TBI-Prognosis Study. Descriptive statistics were used.

**Results** Overall, 33.4 weeks (95% CI = 24.8 to 42.1) were required on average from the start-up package mailing to centers and the start of the screening process. Data sharing and financial agreement were mainly responsible for this delay with an average of 28.6 weeks (95% CI = 20.4 to 36.7) needed to complete the agreement with the coordinating center. REB approval was obtained on average 17.5 weeks (95% CI = 13.8 to 21.2) from the shipping of the study package to the participating centers. Eighty percent of the REBs had members with prior experience in multicenter clinical research, and more than half with specific clinical expertise in critical care medicine or neurology/neurosurgery. A standardized electronic REB submission process was used in most REBs (60%). All centers had experience in implementing multicenter clinical studies. PIs had experience conducting from zero to 40 prior clinical studies and from 3 to 24 years of research experience with protected research time ranging from 5 to 75%. RCs had managed from zero to more than 50 clinical studies. Most centers (87%) organized specific presentation of the study to the critical care medical staff (93%), while some (60%) presented the study to other medical teams. Agreements from other departments such as radiology (87% of centers), electrophysiology (80%) and clinical imaging (73%) were requested in most centers.

**Conclusion** The implementation of a large Canadian multicenter and multifaceted clinical study in the trauma population involved a significant amount of time and energy from both the coordinating and the participating sites. The variable experience of participating sites and teams, as well as the involvement of different medical disciplines, may have had an impact on study implementation time. Delays for REB approval but also for data sharing and financial agreement must be taken into consideration in the timeline for implementing large multicenter clinical studies in trauma.

Optic nerve sheath diameter by bedside ultrasound is a reliable screening test for cerebral edema in the comatose ICU patient

Ahmed Mohamed, N Alharbi, N Alshahedi, M Hussain, O Solaiman

King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

**Introduction** ICU patients may remain comatose after resolution of critical illness. Frequently this is due to delayed sedative clearance but may also result from increases in intracranial pressure (ICP) and cerebral edema. We proposed that measurement of the optic nerve sheath diameter (ONSD) is a rapid, bedside screening test that can be used to quickly identify patients with cerebral edema and increased ICP.

**Methods** This was a prospective, observational study on consecutive patients admitted to a multidisciplinary medical and surgical ICU. Stable patients with unexplained coma and teams, as well as the involvement of different medical disciplines, may have had an impact on study implementation time. Delays for REB approval but also for data sharing and financial agreement must be taken into consideration in the timeline for implementing large multicenter clinical studies in trauma.

Levels of N-terminal pro-brain natriuretic peptide in brain injury patients

T Lentsis, E Kondratyeva, S Kondratyev, N Dryagina

Russian Polenov's Neurosurgical Institute, Saint-Petersburg, Russia

**Introduction** Currently, the most common way to predict the outcome of acute brain damage is to study the level of protein S-100 in the serum. This method lacks specificity as the concentration of protein S-100 significantly increases with age, more for men than women, and there are no data on prognostically significant changes in the level of S-100 after removal of the tumor and cerebral hemorrhages. Endothelins, vasopressin, some cytokines, excess sodium or calcium in serum, activation of the sympathoadrenal system, and tachycardia are the stimulants of brain natriuretic peptide production. The rise of the natriuretic peptide level in cases of acute brain damage has a functionally adaptive nature, based on vasodilation, diuretic action, and ability to reduce sympathoadrenal system activity. Thus, we can suppose that the more severe the damage, the higher the stimulation of natriuretic peptide. In this study we investigate the level of N-terminal pro-brain natriuretic peptide (NT-proBNP) in patients with severe brain damage and find correlation between the level of peptide and outcome.

**Methods** We studied 110 patients having brain injuries of various origins. All patients were divided into four groups. All patients were 20 to 72 years old, 58 men and 52 women. Group 1 (n = 17) – acute TBI, group 2 (n = 29) – patients operated on for the brain tumor, group 3 (n = 36) – ischemic stroke, group 4 (n = 28) – vegetative state. We measured the level of brain natriuretic peptide on days 1 to 3, and then every 7 days for 21 days.

**Results** All patients with severe acute brain damage (groups 1, 2, 3) had a level of NT-proBNP higher than normal (0 to 125 pg/ml). Significant difference in values between the groups was not observed. Level of NT-proBNP above 700 pg/ml and/or the absence of its reduction to normal dynamic indicators was marked by an unfavorable outcome of the disease – severe disability (n = 25) or death (n = 18). For patients from group 4 regardless of their age, sex, severity of condition and treatment results in a level of NT-proBNP below 250 pg/ml.

**Conclusion** In cases of acute severe brain damage the level of NT-proBNP significantly increased. Correlation between the level of NT-proBNP and etiology of acute brain damage was not observed. If the level of NT-proBNP is above 700 pg/ml and/or in the absence of its reduction to normal, then poor outcome of the disease – severe disability or death – can be predicted. Level of NT-proBNP cannot be used as an indicator for the severity of the status for patients in a vegetative state in contrast to patients with acute brain damage.

Cerebral oximetry monitoring in pediatric seizure patients in the emergency department

T Abramo1, B Schnieder1, E Storm1, N Hobart-Porter1, Z Hu1, N Todd1, L Crawley2, M Meredith2, N Dryagina1, S Kondratyev1, S Gortob1

1University of Arkansas School of Medicine, Little Rock, AR, USA; 2University of Tennessee School of Medicine, Memphis, TN, USA

**Introduction** During ictal/post-ictal events, altered cerebral physiology occurs: increased neuronal activity causes significant increase in cerebral metabolism with changes in ipsilateral cerebral blood flow. Standard PED seizure monitoring is by O2 saturation and ET CO2, which yield no direct data about regional cerebral oxygenation/physiology (rSO2). Significant abnormal hemispheric cerebral physiology resulting in neurological injury can occur without knowing because the current monitoring system could not detect the abnormal. Hemispheric abnormality. Cerebral oximetry can provide a rapid, non-invasive detection of each hemisphere’s cerebral physiologic changes during ictal/post-ictal phases. The aim was to study left and right rSO2 values in patients in the pre and post seizure periods and in nonseizing controls.

**Methods** An observational study of seizing and nonseizing patient’s left and right rSO2 readings compared with nonseizure patients.
Conclusions We have demonstrated abnormal hemispheric cerebral physiology during focal or generalized ictal activity. In patients with generalized seizures, the left and right rSO2 values were significantly decreased. In patients with focal seizures, the ipsilateral rSO2 values were significantly different from the contralateral rSO2 readings and correlated to the hemisphere experiencing the focal seizure. In certain patients, during the ictal phase their rSO2 readings rose and stayed or rose then dropped. Overall, cerebral oximetry has shown great monitoring potential for actively seizing patients in the emergency department.

Neurophysiological tests in the neuro ICU

A Marudi1, Y Valzani2, F Valzania1, M Carpentiero1, C Parenti1, S Scacchetti1, S Baroni1, E Bertellini1
1Nuovo Ospedale Civile Sant’Agostino Estense, Modena, Italy; 2University of Modena and Reggio Emilia, Modena, Italy

Introduction Neurophysiological tests (NPTs) are important prognostic and diagnostic tools for patients admitted to the modern neuro ICU (NICU) [1]. Electroencephalography (EEG), somatosensory evoked potentials (SSEP), auditory brainstem response (ABR) and electromyography (EMG) complete clinical examination and radiological findings in patients suffering from post-traumatic brain injury, post-anoxic brain injury, refractory male epilepticus status, and neuromuscular illness. We evaluate the spread of NPTs in our NICU.

Methods We collected data from patients admitted to our NICU from January 2014 to November 2014. We recorded the admission diagnosis and the NPT applied.

Results From January 2014 to November 2014 we performed 521 EEG, 45 SSEP/ABR and 10 EMG. In post-anoxic and post-traumatic brain-injured comatose patients we performed EEG, SSEP and ABR 24 to 48 hours after the admission to predict later prognosis and expected neurological deficit [2]. In the presence of a benign pattern no further evaluation was performed; in the presence of a malignant pattern the NPTs were repeated every 48 to 72 hours according to the protocol of our institute. In post-anoxic comatose patients we recorded EEG during hypothermia to assure burst suppression. In post-traumatic brain-injured patients with a persistent comatose state we use EEG to detect nonconvulsive states which potentially can increase secondary brain injury if untreated. In malignant epilepticus status we use EEG to monitor the effect of therapy and to modify it. In patients who present profound weakness of legs and hands we performed EMG to distinguish primary peripheral myopathy (Guillain Barré, miastenia gravis) from secondary illness acquired in the ICU (critical polyneuropathy, critical myopathy) [3].

Conclusion NPT can improve management of patients admitted to the neuro ICU. The data provided can modify therapeutic strategies and improve outcome in these settings of patients.

Goal-directed cerebral hemodynamic strategy decreases the incidence of postoperative delirium in patients with intracranial hypertension in major abdominal surgery

I Zabolotskikh, N Trembach
Kuban State Medical University, Krasnodar, Russia

Introduction Increased intracranial pressure (ICP) adversely affects anesthesia due to a disturbed cerebral blood flow. In older patients this disturbance may increase the incidence of postoperative delirium (POD) and may lead to a poor outcome [1]. The standard hemodynamic protocol involves maintaining the mean arterial blood pressure (MAP), but in patients with intracranial hypertension it may not be enough to maintain adequate cerebral perfusion. The purpose of this study was to evaluate the protocol of maintaining cerebral perfusion pressure (CPP) in the prevention of postoperative delirium in older patients in abdominal surgery.

Methods A total of 132 ASA 3 patients, undergoing major abdominal surgery (duration 5.2 (4.3 to 6.5) hours) with ICP >12 mmHg evaluated by a venous ophthalmodynamometry [2], were included in our research. Patients were randomized into two groups: MAP group, in which MAP

P462 Hydroquinone shows neuroprotective potential in an experimental ischemic stroke model via attenuation of blood–brain barrier disruption
JH Cho, CW Park, TG Ohk, MC Shin, MH Won
Kangwon National University, Chunchon-si, Gangwondo, South Korea

Introduction
Hydroquinone (HQ), a major benzene metabolite, occurs naturally in various plants and food, and is also manufactured for commercial use. Although many studies have demonstrated the various biological effects of HQ, the neuroprotective effects of HQ following ischemic stroke have not been investigated. Therefore, in this study, we first examined the neuroprotective effects of HQ against ischemic damage in a focal cerebral ischemia rat model.

Methods
It was proven that pre and post treatment with 100 mg/kg HQ protects from ischemia-induced cerebral damage, which was confirmed by evaluation of neurological deficit, positron-emission tomography and 2,3,5-triphenyltetrazoliumchloride staining.

Results
In addition, pre and post treatment with 100 mg/kg HQ significantly attenuated Evans blue dye extravasation, and significantly increased the immunoreactivities and protein levels of SMI-71 and glucose transporter-1 (GLUT-1), which were well known as useful makers of endothelial cells, in ischemic cortex compared with a vehicle-treated group.

Conclusion
Briefly, these results indicate that pre and post treatment with HQ can protect from ischemic damage induced by transient focal cerebral ischemia, and the neuroprotective effects of HQ may be closely associated with the prevention of BBB disruption via increase of SMI-71 and GLUT-1 expressions.

P463 Impact of hyperthermia before and during ischemia reperfusion on neuronal damage and gliosis in the gerbil hippocampus induced by transient cerebral ischemia
CW Park, JH Cho, TG Ohk, MC Shin, MH Won
Kangwon National University, Chunchon-si, Gangwondo, South Korea

Introduction
Hyperthermia can exacerbate the brain damage produced by ischemia. In the present study, we investigated effects of hyperthermia before and during ischemia–reperfusion on neuronal damage and glial changes in the gerbil hippocampus following transient cerebral ischemia using cresyl violet staining, NeuN immunohistochemistry and Fluoro-Jade B histofluorescence staining.

Methods
The animals were randomly assigned to four groups: sham-operated animals with normothermia (normothermia + sham group); ischemia-operated animals with normothermia (normothermia + ischemia group); sham-operated animals with hyperthermia (hyperthermia + sham group); and ischemia-operated animals with hyperthermia (hyperthermia + ischemia group). Hyperthermia (39.5 ± 0.2°C) was induced by exposing the gerbils to a heating pad connected to a rectal thermistor for 30 minutes before and during ischemia–reperfusion.

Results
In the normothermia + ischemia group, a significant delayed neuronal death was observed in the stratum pyramidale (SP) of the hippocampal CA1 region (CA1) 5 days after ischemia–reperfusion. In the hyperthermia + ischemia group, neuronal death in the SP of the CA1 occurred at 1 day post ischemia, and neuronal death was observed in the SP of the CA2/3 region at 2 days post ischemia. In addition, we examined activation of astrocytes and microglia using immunohistochemistry for anti-glial fibrillary acidic protein (GFAP) and anti-ionized calcium-binding adapter molecule 1 (Iba-1). GFAP-positive astrocytes and Iba-1-positive microglia in the ischemic hippocampus were activated much earlier and much more accelerated in the hyperthermia + ischemia group than those in the normothermia + ischemia group.

Conclusion
Based on our findings, we suggest that experimentally hyperthermic precondition before cerebral ischemic insult produces more extensive neuronal damage and glial activation in the ischemic hippocampus.

P464 Effects of long-term exercise on memory recovery in the aged gerbil hippocampus after transient cerebral ischemia
CW Park, JH Cho, TG Ohk, MC Shin, MH Won
Kangwon National University, Chunchon-si, Gangwondo, South Korea

Introduction
Therapeutic exercise is an integral component of rehabilitation for patients with stroke. Despite the high prevalence of cerebral ischemia in the older population, the mechanisms linking restorative exercise to memory recovery from ischemic stroke have not been completely understood in aged animals. In this study, we investigated effects of long-term exercise on neuronal death and memory recovery in the aged gerbil hippocampus after transient cerebral ischemia. We also investigated changes in gliosis, ischemia-induced myelin repair, microvessels, neurogenesis, and growth factor immunoreactivity in the hippocampus to study possible mechanisms of restorative exercise in memory recovery.

Methods
The gerbils were divided into four groups (n = 12 in each group): the sham-operated group (Sham), 4-week sedentary group following ischemia (SD4), 1-week treadmill group following ischemia (TR1) and 4-week treadmill group following ischemia (TR4). Treadmill exercise was started at 5 days after ischemia/reperfusion (I/R) and lasted for 1 or 4 weeks, and the animals were sacrificed 31 days after ischemia.

Results
In this study, 4 weeks of treadmill exercise facilitated memory recovery despite neuronal damage in the CA1 region after I/R. On the other hand, the long-term treadmill exercise alleviated the increased gliosis in the CA1 region, and increased the myelin repairing and microvessels in the CA1 region and DG, and enhanced the ischemia-induced cell proliferation, neuroblast differentiation, neuronal maturation of the newly generated cells, and BDNF expression in the ischemic DG of the aged gerbil.

Conclusion
These results suggest that, in the aged gerbil, long-term treadmill exercise after ischemic stroke could restore the impaired short-term memory function through the cumulative effects of multiple neurorestorative processes.

P465 Association between high arterial oxygen tension and long-term survival after intracerebral hemorrhage
M Fallenius1, R Raj1, M Reinikainen1, S Behnol1, MB Skrjonas1
1Helsinki University Hospital, Helsinki, Finland; 2North Karelia Central Hospital, Joensuu, Finland; 3Kuopio University Hospital, Kuopio, Finland

Introduction
Liberal use of oxygen after brain insults remains controversial [1,2]. We studied whether high arterial oxygen tension...
(PaO$_2$) is associated with decreased long-term survival in patients with spontaneous intracerebral hemorrhage (ICH) treated in the ICU. Methods Data on primary admissions for adult patients (>18 years) treated for ICH in Finnish ICUs between 2003 and 2012 were collected from a nationwide ICU database. Patients were divided into three groups according to the PaO$_2$ value associated with the lowest measured PaO$_2$/FiO$_2$ ratio during the first 24 hours after ICU admission. High arterial oxygen tension was defined as PaO$_2$ > 19.9 kPa; intermediate as PaO$_2$ 13 - 19.9 kPa; and low as PaO$_2$ < 13 kPa. The primary outcome was 6-month mortality.

Results Of the 3,033 patients, 63% ($n = 1,923$) had low PaO$_2$, 29% ($n = 892$) intermediate PaO$_2$, and 7% ($n = 218$) high PaO$_2$. Forty-nine percent of the patients died during the 6-month follow-up. Of these, 75% died before discharge from hospital. Univariate analysis showed that 6-month mortality was higher in the high PaO$_2$ group (61%) compared with the intermediate and low PaO$_2$ groups (52% and 46% respectively, $P < 0.001$). Multivariate analysis, however, showed no statistically significant correlation between high PaO$_2$ and mortality (with the low PaO$_2$ group as the reference category, odds ratio for death (OR) for high PaO$_2$ = 1.10, 95% confidence interval (CI) = 0.76 to 1.58 and for the intermediate PaO$_2$ = 0.96, 95% CI = 0.78 to 1.17).

Conclusion High PaO$_2$ is not predictive of 6-month mortality in patients treated for spontaneous ICH in the ICU. Therefore, targeting higher PaO$_2$ values appears to be a safe approach in order to avoid hypoxemia.

Prediction of 60-day case fatality after aneurysmal subarachnoid hemorrhage: external validation of a prediction model

S Dijkstra, B Roozenbeek, P Brouwer, H Lingsma, D Dippel, L Vergouw, M Vergouwen, M Van der Jagt

Erasmus MC – University Medical Center, Rotterdam, the Netherlands

Introduction Aneurysmal subarachnoid hemorrhage (SAH) is a devastating disease with substantial morbidity and mortality. Prognostic modeling is an important instrument to identify high-risk patients in both clinical practice and research settings. Recently, a prognostic model to predict 60-day case fatality after aneurysmal SAH was developed with data from the International Subarachnoid Aneurysm Trial (ISAT) [1]. Our aim was to externally validate this model in a retrospective cohort of consecutive SAH patients.

Methods We included consecutive aneurysmal SAH patients admitted to one university hospital between October 2007 and October 2011. Exclusion criteria were: age <18 years, hospital admission >28 days after SAH, nonaneurysmal SAH, explicit objection by the patient to view the medical data and missing data on 60-day case fatality. The model’s predictors were age, maximum lumen size of the aneurysm, Fisher grade and World Federation of Neurological Surgeons (WFNS) grade. Two versions of the model were validated: one with WFNS grade scored on admission and the other with WFNS grade assessed at the time of treatment decision, as a proxy to WFNS grade at randomization used in the ISAT. The outcome was 60-day case fatality. Model performance was assessed by studying discrimination, expressed by the area under the receiver operating characteristic curve (AUC), and calibration.

Results A total of 307 patients were included in the validation cohort. The observed 60-day case fatality rate was 30.6%. Discrimination was good, and was considerably better for the model with WFNS grade at treatment decision (AUC = 0.89) compared with the model with WFNS grade on admission (AUC = 0.82). Calibration was poor, with mean predicted probabilities of 17.0% for the model with WFNS grade on admission and 17.7% for the model with WFNS grade at the time of treatment decision.

Conclusion Our results indicate that the ISAT prediction model is generalizable, since the model showed adequate performance in an independent, unselected cohort of aneurysmal SAH patients. The model discriminated well between patients who died and those who survived the first 60 days after SAH. Additionally, use of WFNS grade at the time of treatment decision of the ruptured aneurysm improved model performance. However, since predicted probabilities were lower than observed probabilities, the ISAT prediction model needs to be adapted before use in clinical practice.

Cortical spreading depolarizations in patients with intracerebral hemorrhage: preliminary data

A J Schiefecker, R Beer, M Kofler, B Pfaueler, U Unterberger, P Lackner, G Broessner, P Rohmberg, F Schm1, M Mullina, C Thome, M Fabricius, E Schmutzhard, R Helbok

1Medical University of Innsbruck, Austria; 2Rigshospitalet, Copenhagen, Denmark

Introduction Perihematomal edema (PHE) expansion contributes to increased morbidity and mortality after spontaneous intracerebral
hemorrhage (ICH). Pathophysiology of PHE is incompletely understood. Recently, the role of cortical spreading depolarizations (CSDs) in secondary brain injury was established in subarachnoid and traumatic brain injury patients. However, the value of CSDs after ICH is not known. 

Methods Patients with ICH fulfilling the inclusion criteria were prospectively enrolled in the observational COSBID study (Co-operative Study on Brain Injury Depolarisations). gBSamp (g.tec, Austria) connected to PowerLab and LabChart software (Adinstruments) was used for electrocorticography (EcoG). Electrocardiogram patches at the patient’s shoulder and back served as groundings, and a surface reference electrode was glued on the mastoid. The duration of EcoG depressions was defined as the time between depression onset and start of EcoG recovery in the integral of power calculations (0.5 to 45 Hz; 60 seconds time constant decay). Brain tissue oxygen tension (PbtO2), cerebral blood flow (CBF), cerebral metabolism and intracranial pressure were monitored in the PHE region. Data are presented as median and interquartile range.

Results Eighteen patients with ICH (ICH volume: 54 (33 to 69) ml) were analyzed. Hematoma evacuation was performed in 17 patients, one subject underwent craniectomy only. Patients were 60 (55 to 67) years old and 38% female. Monitoring time per patient was 10 (6 to 14) days. A total of 129 CSDs with 16 (10 to 29) minutes of EcoG depression were observed. Eighty-four percent (n = 15) of patients showed expansion of PHE by 25 (10 to 50) ml within 3 to 6 days after bleeding. Neuromonitoring probes were 35 (23 to 58) mm distant from the EcoG strip. CSDs occurred in 73% (n = 11) of patients with PHE expansion. The interval between CSDs was 98 minutes (25 to 308). CSDs were associated with a significant decrease of PbtO2 (–4 mmHg; –3; –7); duration 10 (5 to 23) minutes in 68% (52/77), CBF changes in 95% (19/20) and metabolic derangement in 80% (80/100) of CSDs. PHE expansion was observed in all patients with spreading convulsions (n = 2) and patients with repetitive CSDs occurring as clusters (n = 3).

Conclusion CSDs are common in ICH patients and associated with perihematomal PbtO2 decreases and metabolic derangement. Especially, clusters of CSDs might be associated with detrimental metabolic changes of the perihematomal brain tissue.

P469

Troponin level as a predictor of prognosis in patients with acute ischemic stroke

H Bayir1, R Dagdil, H Kaymaz, I Yildiz, H Kocoglu1
1Abant Izzet Baysal University, Medical School, Bolu, Turkey; 2Ahi Evran University Education and Research Hospital, Kirsehir, Turkey

Introduction The aim of this study was to identify the association between troponin level and the outcome in patients with acute ischemic stroke.

Methods We retrospectively investigated 152 patients admitted to our reanimation ICU for cerebrovascular accident between 1 January 2013 and 31 December 2013. Inclusion criteria were as follows: patients with acute ischemic stroke, measurement of serum troponin level and electrocardiography performed within 24 hours of admission. Not included were patients with intracerebral hemorrhage, no brain imaging or electrocardiography, previous myocardial infarction, stable or unstable angina pectoris before admission, previous coronary angioplasty or coronary bypass surgery.

Results Of 152 patients, 51 patients were excluded from the study because of the exclusion criteria. The serum troponin level was elevated in 81 patients. The patients were divided into two groups; patients in group 1 (n = 81) with serum troponin level >0.01, and those in group 2 (n = 20) with serum troponin level ≤0.01. For 1-month follow-up results of patients, death had occurred in 50.6% (n = 41) of patients in group 1 and in 25% (n = 5) of patients in group 2. There was a significant positive correlation between the increase in troponin level and death within 1 month (P = 0.025; P = 0.040). The best cutoff point revealed by the ROC curve of troponin was 0.291 mg/l at which the sensitivity was 73% and the specificity was 79% when used for prediction of death within 1 month (area = 0.319, CI = 0.214 to 0.423, P = 0.021; Figure 1).

Conclusion These results suggest that increased serum troponin level at admission is associated with higher mortality rate. Troponin positivity on admission is an independent prognostic predictor in acute ischemic stroke.

Increased risk of ischemic stroke in patients with burn injury: a nationwide cohort study in Taiwan

TY Hung1, YC Su2
1Zhongying Branch of Taipei City Hospital, Taipei, Taiwan; 2Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi, Taiwan

Introduction The results of studies attempting to assess the risks of ischemic stroke in patients with burn injury have been conflicting. We investigated the risks of ischemic stroke in hospitalized burn injury patients in Taiwan to evaluate whether the risk is higher compared with the general population.

Methods The data from 1 million National Health Insurance beneficiaries were utilized. All adult beneficiaries were followed from 1 January 2005 until 31 December 2012 to identify those who developed ischemic stroke. Meanwhile, each identified patient with burn injury was matched with 100 unexposed patients based on the high-dimensional propensity score. Cox regression models were applied to compare the hazards of ischemic stroke in the matched cohorts.

Figure 1 (abstract P470). Patient flowchart of enrollment.
Results A total of 743,237 patients were enrolled. After matching, 1,763 burn injury patients and 176,300 unexposed patients were selected. The adjusted hazard ratio of ischemic stroke was significantly increased in burn injury patients (1.84; 95% CI, 1.43 to 2.36). Such phenomenon remained significantly after 12 months (1.54; 95% CI, 1.11 to 2.13). See Figures 1 and 2.

Conclusion The risk of ischemic stroke is higher in patients hospitalized with burn injury than in the general population, and the effects may be extended longer than expected previously.

Effect of coronary artery bypass grafting surgery with a pump on cerebral blood flow in high-risk patients
R Juliano, G Ferreira, L Camara, S Zeff erino, M Lima, R Nogueira, E Bor-Seng- Shu, E Osawa, J Jardim, J Almeida, G Falas, L Hajar
Heart Institute, São Paulo, Brazil

Introduction Coronary artery bypass grafting (CABG) surgery usually improves myocardial contractility, reducing cardiovascular events. However, it is a high-risk procedure associated with significant neurological complications, including stroke, delirium and cognitive impairment. The pathophysiology of these complications is not very well known, and may include low flow state after surgery, low cardiac output, embolism and reperfusion lesion. The aim of this study is to prospectively evaluate the cerebral hemodynamics through transcranial color and spectral Doppler sonography in high-risk patients undergoing cardiac surgery with a pump.

Methods This was a prospective, single-center study, performed at the Heart Institute from University of São Paulo. From May to November 2014 we included 35 patients in the study, aged older than 18 years old, submitted to CABG with a pump, with EuroSCORE higher than 6 or left ventricular ejection fraction lower than 40%. Transcranial color and spectral Doppler sonography was performed 48 hours before surgery (T0), 7 days (T1) and 6 months after surgery (T2). We used a probe of 2.5 to 2 MHz (Doppler Box DWL/Compumedics, Singen, Germany). All recordings were taken with the patient in a supine position. We measured the middle cerebral artery mean flow velocity and pulsatility index. The end-expiratory pressure of CO2 (PETCO2) was measured with infrared capnography attached to a face mask. Blood pressure, hematoctit and axillary temperature was also recorded.

Results The mean age of patients was 64 years; most patients were male (74%). Middle cerebral artery mean flow velocity increased significantly after cardiac surgery. It was 53.89 ± 17.23 m/sec at T0, 61.48 ± 15.18 m/sec at T1 and 59.27 ± 16.12 m/sec at T2 (P = 0.029). The pulsatility index was similar at all time points (0.88 ± 0.25 at T0, 0.85 ± 0.24 at T1 and 0.91 ± 0.25 at T2, P = 0.146). There was a significant difference in the levels of hemoglobin (13.19 ± g/dl 1.97 at T0 and 9.64 ± 1.48 g/dl at T1, P = 0.002). However, this difference was not maintained at T2 (12.7 ± 2.02 g/dl at T2, P = 0.252). There were no differences regarding PETCO2, at the time points.

Conclusion After cardiac surgery with a pump in high-risk patients, improvement of cerebral hemodynamic occurs, perhaps due to the optimization of cardiovascular function. These findings must be better investigated.

Reference
demonstrated a loss of cross-sectional area of lower limb muscles during a 10-day intensive care stay. In this study, we have looked at how markers of muscle architecture (muscle thickness, pennation angle and fascicle length) change in the lower limb, as well as looking at changes in muscle thickness in the upper limb.

Methods Following ethical approval, patients who were intubated and ventilated in one of two critical care departments were assented to take part in the study by their next of kin. B-mode ultrasound scans of the right biceps, vastus lateralis and the medial head of gastrocnemius were performed on days 1, 5 and 10. Scans were not performed in patients once they were free of sedation. Muscle thickness (MT) was measured in all three muscles, with pennation angle (PA) being measured in the lower limb muscles. Fascicle length (FL) was derived from PA and MT.

Results Twenty patients were recruited, of which 15 were scanned on day 5, and eight were scanned on day 10. In the biceps, there were no alterations in MT over 5 or 10 days. MT of the vastus lateralis significantly decreased on day 5 (1.77 ± 0.06 mm muscle loss, P = 0.03) and day 10 (5.58 ± 0.09 mm muscle loss, P = 0.01). There was also a significant loss in PA over 5 days (1.48 ± 0.63°, P = 0.01) and 10 days (2.96 ± 0.72°, P = 0.01). However, FL was unchanged over time. There was a significant relationship between size of PA and percentage loss of PA and FL in the first 5 days. In contrast, we have demonstrated a sparing effect on the muscles of the upper limb compared with the lower limb. These findings may have implications for rehabilitation and interventions to preserve muscle mass.

P474 Predictive value for weakness and 1-year mortality of screening electrophysiology tests in the ICU
H Van Mechelen1, G Hermans1, F Bruyninckx2, T Vanhullebusch1, B Clerckx1, P Meerseman1, Y Debaveye1, MP Casar1, A Wilmer1, PJ Wouters1, I Vanhorebeek1, R Gosselink1, G Van den Bergh1
KU Leuven, Belgium; UZ Leuven, Belgium

Introduction Muscle weakness in long-stay ICU patients contributes to 1-year mortality [1]. Whether electrophysiological screening is an alternative diagnostic tool also in unconscious/uncooperative patients remains unknown. The aims of this study were to determine the diagnostic properties of abnormal compound muscle action potential (CMAP), sensory nerve action potential (SNAP) and spontaneous electrical activity (SEA) for Medical Research Council (MRC)-sum score defined weakness and their predictive value for 1-year mortality.

Methods Data were prospectively collected during the EPaNIC trial (ClinicalTrials.gov NCT00512122) [2] from October 2008 to November 2010. From day 8 onwards, nerve conduction studies and electromyography were performed weekly in 642 long-stay and 88 randomly selected short-stay patients and muscle strength was assessed in cooperative patients using the MRC-sum score. The electrophysiologist was blinded for the clinical assessments of the physiotherapists and vice versa. The two primary outcomes were: sensitivity, specificity, positive and negative predictive values of abnormal CMAP, SNAP and SEA for weakness (MRC-sum score <48); and the predictive value for 1-year mortality of abnormal findings on first electrophysiological screening. This association was assessed by univariate and multivariate analyses correcting for weakness and other risk factors, including baseline risk factors, comorbidities, illness severity and ICU exposures.

Results A total of 730 patients were electrophysiologically screened, of which 432 were tested for weakness. On day 8, only normal CMAP excluded weakness with a high negative predictive value (80.5%). By day 15, abnormal SNAP and the presence of SEA revealed a high positive predictive value (91.7% and 80.0%, respectively). On day 8, only a reduced CMAP was associated with higher 1-year mortality (35.6% vs. 15.2%, P <0.001). This association remained significant after correction for weakness and other risk factors (OR: 2.463 (95% CI: 1.113 to 5.452), P = 0.026). Also among conscious/cooperative patients without weakness, reduced CMAP was independently associated with a higher likelihood of death within 1 year (HR: 2.818 (95% CI: 1.074 to 7.391), P = 0.035).

Conclusion The diagnostic properties of electrophysiological screening vary over time. Abnormal CMAP documented early during critical illness carries information about longer-term outcome, which should be further investigated mechanistically.

Acknowledgement HVM and GH contributed equally.

Methods We targeted 103 ICU patients in Okayama University Hospital between April 2013 and February 2014. Delirium was diagnosed using the Confusion Assessment Method – ICU. On admission, blood was obtained for biomarker analysis. Patients with severe head injury and under 16 years old were excluded. P <0.05 was considered statistically significant.

Results Thirty-seven delirious and 66 nondelirious patients were included. We found that delirious patients tended to have higher B-type natriuretic peptide (BNP) levels and to have lower estimated glomerular filtration rate (eGFR) (BNP: delirious patients 188.6 pg/ml, nondelirious patients 74.2 pg/ml (P = 0.001); eGFR: delirious patients 58.6 ml/minute/1.73 m², nondelirious patients 81.3 ml/minute/1.73 m² (P = 0.020)). Procalcitonin (PCT) and D-dimer were almost the same between both for intentional and unintentional injury. About 50% of patients presenting with self-inflicting injuries in emergency departments had delirium and nondelirious patients (PCT: delirious patients 0.202 ng/ml, nondelirious patients 0.150 ng/ml (P = 0.613); D-dimer: delirious patients 5.25 ng/ml, nondelirious patients 5.35 ng/ml (P = 0.714)).

Conclusion BNP and eGFR in ICU admission was associated with delirium. PCT and D-dimer in ICU admission was not associated with delirium. BNP and eGFR might evaluate a predictor of delirium in ICU.

Prevalence of psychiatric disorders in trauma patients: results from a major trauma unit
M Adlam, A Feehan, V Metaza
King’s College Hospital, London, UK

Introduction Mental illness has been recognised as a potential risk factor both for intentional and unintentional injury. About 50% of patients presenting with self-inflicting injuries in emergency departments had previous known psychiatric disorder (PD) [1,2], whereas individuals with mental illness were admitted for unintentional injury twice as often as those without [3]. We aimed to assess the prevalence of PD in trauma patients being admitted to a major trauma ICU and compare it with the nontrauma population.

Methods We retrospectively reviewed all admissions from January 2010 to December 2013 in a tertiary, mixed ICU that serves a London major trauma centre (MTC) hospital. Data obtained were age, APACHE II score, reason for admission, length of stay (LOS), mortality and a diagnosis of depression, bipolar, self-harm, psychosis, schizophrenia and suicide attempt.

Results Of 978 trauma patients admitted to the ICU, 68 (7%) had a known PD. Their diagnoses are shown in Figure 1. Median APACHE II score and unadjusted mortality were 13 and 18% respectively in the PD group (15 and 12% in the entire cohort, P>0.05). Patients suffering from more than one diagnosis or self-harm alone had increased median LOS (6 vs. 4 days in the entire cohort, P>0.05).

Conclusion Trauma patients with PD have increased mortality and LOS. MTCs provide a unique opportunity to identify mental illness during hospitalisation through screening and intervention programmes. Integration of mental health services into ICU care should be examined, as it might provide an efficient and cost-effective way of decreasing the risk of reinjury.

References
The presence of delirium in critical care is an independent risk factor for mortality: for every day of delirium, there is an additional 10% relative risk of death at 1 year [2]. A delirium prediction tool PRE-DELIRIC has been recently developed and calibrated in a multinational project [3]. This study aimed to determine the utility of PRE-DELIRIC on our ICU.

Methods This study prospectively investigated 41 patients. Medical and surgical general ICU patients were included after 24 hours of sedation and mechanical ventilation. The researchers calculated PRE-DELIRIC scores for each patient. PRE-DELIRIC involves recording 10 variables, submitted into an online algorithm that estimates the percentage risk of delirium. We diagnosed delirium with the CAM-ICU which was performed 12 hourly [4].

Results The PRE-DELIRIC scores predicted a mean rate of delirium of 39%. PRE-DELIRIC risk scores ranged from 4 to 93% (Figure 1). Six (15%) patients developed delirium in the first 24 hours following extubation. Fifteen (37%) of patients were predicted 20% or less probability of delirium. Twelve (29%) patients developed delirium at any point during their ICU stay. This resulted in 36 total delirium bed-days.

Conclusion Our observation that <30% of patients experienced delirium is less than the reported prevalence in similar settings and our own audits. This study demonstrates that there is some agreement between recorded rates of delirium and predicted rates using PRE-DELIRIC. We suggest that PRE-DELIRIC can be used in quality/audit work on UK ICUs in order to assess attempts to improve the management of delirium. Further work is required to assess the utility of PRE-DELIRIC as a risk assessment tool in individual patients.

Propofol sedation reduces contraction and motion of diaphragm in humans: preliminary results
G Ranieri, M Luigi, F Belisio, M Rocco, RA De Blasi
Sant'Andrea, Rome, Italy

Introduction Among drugs used for sedation, propofol has a primary role [1]. Despite propofol being described to exert a relaxant effect on skeletal muscle, no data showing its action on diaphragm are reported. The aim of this observational study on humans is to apply ultrasound to assess propofol’s effect on diaphragmatic contraction and motion during endoscopic procedures.

Methods We investigated seven consecutive patients undergoing gastroscopy or colonoscopy in the endoscopy unit of our hospital. Patients received propofol at a dose able to induce and maintain sedation to level 6 of the Ramsay Sedation Scale during the procedure. Measurements were obtained on right side of the thorax in millimeters; diaphragmatic motion (DM) and diaphragmatic motion at maximal inspiration (DM forced) were measured in M-Mode with a 3.5 MHz array convex probe placed on the midclavicular line using the liver acoustic window. Thickness at end inspiration (TEI) and thickness at end expiration (TEE) were measured in M-Mode with a 10 MHz vascular probe. The thickening fraction (TF) was calculated: (TEI – TEE) / TEE [2].

Time points of measurements were taken when the patient arrived in the surgery room (Baseline), 1 minute after level 6 of the Ramsay Sedation Scale was obtained (Sedation) and 5 minutes after the patient had a recovery to level 1 on the Ramsay Sedation Scale (Awakening).

*P <0.001 versus baseline. P = 0.043 versus baseline. P <0.001 versus sedation. P = 0.030 versus baseline. P = 0.012 versus baseline. P = 0.353 versus baseline. P = 0.041 versus sedation. P = 0.022 versus baseline.

Methods A literature survey via MEDLINE and Embase search with keywords ‘PRIS’, ‘lactic acid’, ‘propofol’ and ‘sedation’. All cases in English, French and Spanish were identified. Exclusion criteria were onset >48 hours, unclear description of time pattern and dose.

Results Twenty-two cases of early PRIS were found. These concerned 10 pediatric versus 12 adult patients. Eleven were identified in the ICU versus 11 in the operating room. The survival rate of early PRIS was 95.5%, and morbidity was restricted to four patients. In the adult subgroup, the mean propofol dose was 4.9 mg/kg/hour. Triggering factors such as use of catecholamines and corticosteroids were found in 36.4% and 45% of patients. In total, 3/22 cases matched Bray’s definition of PRIS. In 14/22 cases, lactic acidosis was interpreted as onset of PRIS.

Conclusion Compared with a review by Fudickar [1], we found significant differences in critical dose, risk factors, symptomatology and morbidity/mortality between PRIS and early PRIS cases. As criticisms are offered, a question is whether these cases really are the onset of the fatal syndrome PRIS. Therefore, we completed differential diagnosis of lactic acidosis and found that not all possible causes (for example, hyperglycemia, ketonemia, pharmacologic confounders as biguanides, epinephrine) were ruled out in most cases. This is important since PRIS is an exclusion diagnosis. The existence of early PRIS should indeed be questioned and investigated by large, multicenter observational trials.

Short-term propofol infusion syndrome (PRIS): fact or fiction?
J Vandenbrande
University Hospitals Leuven, Belgium

Introduction Propofol infusion syndrome (PRIS) is a rare propofol complication, leading to cardiac failure. It was first described in critically ill children and in adults with traumatic brain injury. Pathophysiology is unknown although common factors are the prolonged (>48 hours) use of high-dose (>5 mg/kg/hour) propofol combined with elevated levels of catecholamines and corticosteroids. Recently, case reports of early-onset PRIS during anesthesia and in the early postoperative setting were published. In many of these, lactic acidosis is interpreted as onset of PRIS. Criticism offers that it might concern a poor differential diagnostic approach or an observational bias. Also, lactic acidosis is not an obligate PRIS symptom and incidence of lactic acidosis during propofol sedation is unknown. To gain insight into the incidence and characteristics of early PRIS, we performed a systematic review on early PRIS cases.

Figure 1 (abstract P479). Range of PRE-DELIRIC scores.
Data analyzed are reported in Table 1 and expressed as mean (SD). *ANOVA was used to compare data for repeated measurements. Post hoc statistical comparison with Bonferroni's test was used to identify significant differences.

**Results**

During propofol administration TE1 reduced 19% whereas after awakening it increased 14.5% but did not reach baseline. Conversely TE2 did not change during the study. During propofol sedation, TF decreased 34% and returned to baseline after recovery. DM showed 29% reduction during propofol administration whereas the forced diaphragmatic motion tested when patients were conscious (forced DM) did not evidence any change.

**Conclusion**

In this observational study, ultrasound assessed that propofol causes a reduction of diaphragmatic contraction and motion during endoscopic procedures.

Delirium knowledge and assessment by ICU practitioners in South Africa: results of a national survey

S Chetty1, P Paruk1, C Bagnall2,
University of the Witwatersrand, Johannesburg, South Africa

**Introduction**

Delirium recognition in critically ill patients is considered to be important taking into account the poor outcomes associated with its occurrence. The purpose of this study was to evaluate knowledge pertaining to delirium as well as the implementation of screening practices. This study constituted a component of a survey that explored current sedation-related practices in South African ICUs.

**Methods**

Following approval from the University Human Research ethics committee, a validated questionnaire was distributed electronically to physician members of various medical databases in South Africa as South Africa does not have a formal registry of critical care practitioners.

**Results**

One hundred and twenty-six of 174 respondents indicated that they practice in the ICU setting. Sixty-six per cent were specialists and mainly anaesthesiologists (42%), whilst 32% were critical care subspecialists. The respondents indicated that on average 30 ± 20% of their patients experience delirium. Eighty per cent of the respondents indicated that delirium impacts significantly negatively on patient outcomes whilst 1% indicated that there was no such association. Delirium screening is achieved mainly by clinical assessment (77%). Twenty-four per cent utilise an objective tool to screen for delirium and amongst them the CAM-ICU is utilised by 80%. Amongst delirious patients the sedative of choice is dexmedetomidine in the majority. However, 20% prescribe midazolam as a first choice in this setting.

**Conclusion**

The findings are comparable with reports of similar surveys conducted in other regions. The delirium screening method is inadequate as the vast majority do not utilise an objective method.

L Roxapine to control agitation during weaning from mechanical ventilation: a randomized controlled trial

S Gaudry1, B Sztrany2, R Sonnevile3, B Megarbane3, C Clech3, J Ricard3, D Hajage3, D Dreyfuss3

1 Hôpital Bichat, Paris, France; 2 Hôpital Lariboisière, Paris, France; 3 Hôpital S Gaudry1, B Sztrymf2, R Sonneville3, B Megarbanne4, C Clec'h5, J Ricard1, D Hajege3, D Dreyfuss3

**Introduction**

Weaning from prolonged mechanical ventilation (MV) in the ICU may be impeded by the occurrence of agitation. Loxapine had the ability to control agitation without affecting the efficacy of spontaneous ventilation in an observational study, justifying the implementation of a randomized controlled trial.

**Methods**

We conducted a multicenter, placebo-controlled, parallel group, randomized trial at five French ICUs between November 2011 and November 2013. Patients (aged >18 years) under MV for more than 48 hours who were potential candidates for weaning from the ventilator and who exhibited agitation defined by a Richmond Agitation Sedation Scale (RASS) >2 after sedation withdrawal were randomly assigned to receive either loxapine or placebo. All participants were masked to group of allocation. After randomization, patients received 150 mg loxapine or placebo by nasogastric tube. RASS was monitored every 4 hours. A second dose of loxapine or placebo was administered if agitation persisted or worsened. In case of severe agitation, usual sedation (benzodiazepines and morphine agents) was immediately resumed. Extubation was contemplated when patients were conscious and calm. The primary endpoint was the time between the first administration of loxapine or placebo and successful extubation (no reintubation in the following 48 hours). Three hundred patients were necessary to have 90% power to detect a 2-day reduction of weaning time in the loxapine group with a one-sided type I error rate of 5%.

**Results**

The trial was discontinued after 101 patients had been randomized because of insufficient enrollment. Fifteen patients withdrew consent, leaving 86 patients for analysis. Forty-seven patients were assigned to the loxapine group and 39 to the placebo group. Median time to successful extubation was 3.2 days in the loxapine group and 5 days in the placebo group (RR = 1.2, 95% CI = 0.73 to 1.88; P = 0.45). During the first 24 hours, sedation was more frequently resumed in the placebo group (44% vs. 17%; P = 0.01). One patient had a transient seizure in the loxapine group.

**Conclusion**

These results are consistent with the hypothesis of 2 days reduction of the median weaning time in the loxapine group, but the difference was not statistically significant. Loxapine reduces the need for resuming sedation during weaning from MV. Given the quality of the data and methodology, these results may be useful in future meta-analyses.

Prolonged dexmedetomidine infusion and drug withdrawal in critically ill children

A Haenecour, A Goodwin, W Seto, C Urbain, P Laussen, C Balti

The Hospital for Sick Children, Toronto, ON, Canada

**Introduction**

We investigated the incidence, symptoms and risk factors for withdrawal associated with prolonged dexmedetomidine use. Dexmedetomidine is an α2-adrenergic receptor agonist, with anxiolytic, analgesic and sedative properties. Intended for short-term use, there is increasing literature describing prolonged use for sedation. However, this raises the potential of withdrawal syndrome and there is no recommendation for the discontinuation of dexmedetomidine. Our goals included examining the hemodynamic effects of discontinuation of dexmedetomidine and role of clonidine in patients with prolonged dexmedetomidine use.

**Methods**

A retrospective review of patients admitted to the critical care unit who had exposure to dexmedetomidine for longer than 48 hours, between 1 January 2014 and 15 July 2014. Data included patient demographics, dexmedetomidine exposure (bolus dose, total cumulative dose, duration), other sedative exposure, withdrawal symptoms measured by WAT-1 score, nursing subjective assessment and treatment given for withdrawal. Each potential withdrawal episode was reviewed by two reviewers. Hemodynamic parameters were analyzed to assess hemodynamic changes associated with discontinuation of dexmedetomidine. Descriptive statistics were used with t-test and chi-square test. Median and interquartile range (IQR) are reported.

**Results**

Of 53 patients accounted for 69 unique dexmedetomidine treatment courses. Median age at the time of dexmedetomidine infusion was 3 months (range 1 day to 3 years). Dexmedetomidine dose ranged from 0.1 to 2 μg/kg/hour with a median cumulative dose of 87 μg/kg (IQR 53, 156). Median duration of exposure to dexmedetomidine was 124 hours (IQR 76, 178) with a maximum duration of 466 hours. We identified 24 separate episodes of withdrawal (incidence 35%). Most common symptoms were agitation (100%), fever (67%), vomiting/retching (46%), loose stools (29%) and decreased sleep (20%). Statistical analysis showed that factors significantly associated...
with withdrawal were cumulative dose ($P = 0.01$) and duration of use of dexmedetomidine ($P = 0.02$). Duration of opioids exposure prior to dexmedetomidine wean was also a risk factor for withdrawal ($P = 0.01$). Use of clonidine as a transition from dexmedetomidine did not protect against withdrawal ($P = 0.59$).

**Conclusion** This study showed that withdrawal syndrome is associated with prolonged infusion of dexmedetomidine. Patients with higher cumulative doses and longer duration of exposure were at more risk. Our results suggested that clonidine use is not protective for withdrawal from dexmedetomidine.

**Weaning from extracorporeal membrane oxygenation: experience with dexmedetomidine in seven adult ARDS patients**

M Cozzolino, A Franci, A Parisi, L Tadini Buoninsegna, B Loriga

A.O.U. Careggi, Firenze, Italy

**Introduction** Sedation in the ICU is a basic therapeutic procedure to increase tolerance of invasive treatments and reduce discomfort. Extracorporeal membrane oxygenation (ECMO) is a highly invasive treatment and prolonged sedation may be required. Patients undergoing ECMO represent a challenge with respect to sedation. Initially, deep sedation may be required to optimize ventilation and circuit–patient flows and to minimize oxygen consumption. The other critical phase is represented by weaning from ECMO support. Optimal sedation is not clearly defined, moreover there are no data on sedation practices with dexmedetomidine (DEX) in adult patients undergoing ECMO. In contrast to other sedatives, DEX has analgesic effects without respiratory depression, and could be useful to facilitate spontaneous respiratory activity during recovery from sedation.

**Methods** We investigate the role of DEX as a sedative agent used during recovery from deep sedation and weaning from extracorporeal support in patients on vv-ECMO. From May 2014 to October 2014 we prospectively enrolled seven patients affected by ARDS of different etiologies treated with vv-ECMO. The mean age was 53.7 ± 7.9 years and the mean ICU stay was 21.4 ± 11.5 days. Initially, all patients were sedated with association of opioids and GABA receptor agonists, following the internal protocol. At the time of weaning from ECMO, ruled out cardiovascular instability, we started the administration of DEX (0.7 μg/kg/hour, without initial bolus) with progressive decrease of the dose of other sedative drugs.

**Results** The mean duration of DEX infusion was 6.1 ± 4.8 days. Except for one patient, who received DEX as a single drug after suspension of other sedatives, a low-dose infusion of another sedative (<50% compared with initial dose) was maintained. Three patients presented adverse events: two bradycardia and one hypotension. In four patients DEX was discontinued after recovery of respiratory function; in two patients deep sedation for ventilatory dysynchrony was needed so other sedative drugs were started. Only in one patient was the drug suspended for extreme bradycardia, resolved after suspension.

**Conclusion** In our study, DEX allowed the reduction of doses of other sedative drugs during weaning from vv-ECMO; this may lead to a cooperative sedation, promoting spontaneous breathing. Side effects described and the cost–benefit ratio must still be verified extensively in patients during weaning from ECMO.

**Short-term sedation of mechanically ventilated ICU patients with propofol, benzodiazepines, or dexmedetomidine: systematic review and meta-analysis on awakening and recovery times**

A Feuersenger, L Pradelli, A Aliano, F Baron, M Westphal

Fresenius Kabi Deutschland GmbH, Bad Homburg, Germany; 1AdRes, Torino, Italy; 2Fresenius Kabi ELAMA, Paris, France

**Introduction** Sedation in the ICU is crucial in reduction of patients’ discomfort, in particular in patients undergoing mechanical ventilation to help tolerate intubation and reduce pain and anxiety. Propofol (Pr) is a widely used option, but other viable alternatives for short-term sedation (STS; that is, <24 hours) include benzodiazepines (BDZ) and dexmedetomidine (Dx). We aimed at pooling all available evidence on the comparative effects of Pr in terms of awakening and recovery times after STS in mechanically ventilated ICU patients.

**Methods** We planned a systematic literature review searching Medline and Scopus and performed a meta-analysis on direct comparisons reporting on weaning time (Tw), duration of mechanical ventilation (Tmv), time to extubation (Tex) and length of stay in the ICU (Ticu). The primary analysis considered only data from RCTs, while in a secondary analysis observational studies were also included.

**Results** The literature search identified 15 relevant RCTs, of which 11 versus BDZ, and a further five observational studies, of which one versus BDZ. When compared with BDZ, Pr associated with significantly reduced Tw (−1.6 hours, 95% CI: −2.5 to −0.8), Tex (−2.0 hours, 95% CI: −3.7 to −0.2), and Ticu (−0.5 hours, 95% CI: −0.8 to −1.4); no statistically significant difference resulted when comparing Pr and Dx. When nonrandomized evidence was included, results did not change significantly.

**Conclusion** In conclusion, Pr is associated with shorter awakening and recovery times after STS than BDZ, while no difference could be shown when Pr was compared with Dx.

**P487**

**Effects of administration of dexmedetomidine on inflammatory responses and severity in severe septic patients**

T Taniguchi, M Okajima, K Sato, T Noda

Kanazawa University, Kanazawa, Japan

**Introduction** Recently, several animal studies observed that dexmedetomidine (DEX), a new sedative and α₂-adrenoceptor agonist, inhibited the inflammatory responses [1-3]. Moreover, DEX was reported to have anti-inflammatory effects in patients [4,5]. However, these studies were the small-sized studies and there are few studies about the effects of long-term administration of DEX in severe septic patients. The present study evaluated the effects of long-term administration of DEX on inflammatory responses and severity in severe septic patients. We hypothesize that the administration of DEX has beneficial effects for severe septic patients.

**Methods** In 66 patients (M/F 44/22, mean age 66 years) with severe sepsis, who were administered propofol (0.5 to 4.0 mg/kg/hour) only for sedation, 42 patients (M/F 28/14, mean age 67 years) were administered DEX (0.2 to 0.7 μg/kg/hour) for more than 24 hours in addition to propofol (DEX group). Twenty-four patients were not administered DEX (Control group). Primary outcome was changes in inflammatory responses at 48 hours after the administration of DEX or none, and secondary outcomes were changes in APACHE II and SOFA scores at 48 hours after the administration of DEX or none.

**Results** The administration of DEX occurred for a mean 130 hours (24 to 433 hours) in the DEX group. White blood cell counts, C-reactive protein (CRP) and procalcitonin (PCT) in both groups significantly decreased after the administration of DEX or none. However, CRP and PCT in the DEX group were significantly lower than those in the control group: CRP 7.7 (5.0) versus 13.6 (7.9) mg/dl; P < 0.05, PCT 7.6 (11.7) versus 18.6 (11.6) ng/ml; P < 0.05, mean (SD), APACHE II and SOFA scores in both groups decreased after the administration of DEX or none, but APACHE II and SOFA scores in the DEX group were lower than those in the control group: APACHE II 10.8 (4.8) versus 15.2 (5.1); P < 0.05, SOFA 3.6 (2.0) versus 5.8 (2.9); P < 0.05, mean (SD).

**Conclusion** In the present study, the long-term administration of DEX has beneficial effects of inflammatory responses and severity for severe septic patients.

Characteristics of the use of dexmedetomidine in critically ill children: a Brazilian study
PL Lago, C Andreolli, J Piva, E Baldisso
Hospital de Clínicas de Porto Alegre, Brazil

Introduction To describe the main indications, doses, infusion length and side effects of dexmedetomidine (DEX) administered to children and adolescents admitted to the pediatric ICU (PICU).

Methods A retrospective observational study including children (<18 years) admitted to a Brazilian PICU who received DEX between November 2011 and June 2014. Demographic data, indications, initial dose, maximum dose and time of infusion of DEX, side effects and impact on heart rate (HR) and mean arterial pressure (MAP) 6 and 24 hours after the start of infusion.

Results A total of 77 children with a median age of 15 (4 to 84) months, weight of 10 (5.7 to 20) kg and length of ICU stay of 8 (5 to 14) days received DEX, with a mortality rate of 9%. Indications were: weaning from mechanical ventilation (32.5%), neurosurgical postoperative (NCI) and upper airway surgery (VAS) (24.7%), non-invasive ventilation (13%), refractory tachycardia (6.5%) and other indications (23.3%). There was no difference between the initial and maximum doses and infusion length. There was a significant decrease in MAP and HR after 6 hours infusion of DEX in the total group; however, no significant difference occurred between groups when analyzing MAP and HR 24 hours after the start of infusion ($P = 0.798$ and $0.379$, one-way ANOVA, respectively).

In six patients (8%) DEX was suspended for possible side effects.

Conclusion Increased DEX indications have been observed in the pediatric population. In this study DEX was demonstrated to be a safe and tolerable drug with few side effects, especially related to the cardiovascular system.

Psychometric comparison of three behavioral scales for the assessment of pain in critically ill patients unable to self-report
G Papakitsos1, A Kapsali1, T Papakitsou2
1GHA, Arta, Greece; 2General Hospital Messologi, Greece

Introduction Pain assessment is associated with important outcomes in ICU patients but remains challenging, particularly in noncommunicative patients. Use of a reliable tool is paramount to allow any implementation of sedation/analgesia protocols in a multidisciplinary team. This study compared psychometric properties (inter-rater agreement primarily; validity, responsiveness and feasibility secondarily) of three pain scales: Behavioural Pain Scale (BPS/BPS-NI, that is BPS for non-intubated patients), Critical Care Pain Observation Tool (CPOT) and Non-Verbal Pain Scale (NVPS), the pain tool routinely used in this 16-bed medical ICU.

Methods In a prospective observational study of ED polytraumatized patients ($n = 23$), mean Acute Physiology and Chronic Health Evaluation II (APACHE II) score ($n = 63$) was measured (in the first of three pain scales: Behavioural Pain Scale (BPS/BPS-NI, that is BPS for non-intubated patients), Critical Care Pain Observation Tool (CPOT) and Non-Verbal Pain Scale (NVPS), the pain tool routinely used in this 16-bed medical ICU.

Results Polytraumatized patients showed differences in TAC with reference to control subjects. ED polytraumatized patients showed high FRAP values. We found that FRAP values were inversely correlated with APACHE II score ($r = -0.266$, $P < 0.01$) suggesting that, in trauma patients, increased antioxidant response, as measured by the FRAP assay, could be a pathophysiological response to stress. Albumin and uric acid concentrations reproduced the FRAP trend with severity.

Conclusion FRAP values in trauma ED patients are independently influenced by age ($\beta = 0.271$, $P < 0.021$), APACHE II score ($\beta = -0.356$, $P < 0.002$) and head trauma ($\beta = -0.219$, $P < 0.045$). These results accentuate the influence of trauma location and severity in TAC changes. The TAC response in ED patients reinforces the need for adequate tailoring of treatments aimed at their recovery, such as antioxidant therapies.

P490
Best pain management for critical older patients in the surgical ICU
W Huang
Mackay Memorial Hospital, Taipei, Taiwan

Introduction To determine which of three methods of pain management provided the best pain control in severe ASA III older patients in the surgical ICU (SICU). As technology improves, more older patients benefit from surgery and need SICU care. Older surgery patients frequently present two medical problems. First is unspecific symptoms and decreased pain sensation resulting in delayed diagnosis. Second, they usually are not given enough perioperative pain relief. Optimal pain management results in perioperative stable hemodynamic status and decreased morbidity, mortality, length of stay and medical costs.

Methods A retrospective cohort study chart review of 1,872 all-cause patients in a 16-bed SICU during April 2011 to September 2012. Unconsciousness, uncooperative, ASA <III and <65-year-old patients were excluded. The primary point was to compare effectiveness of three different methods of pain management: PR.N. i.v. Demerol/NSAID (D/N), i.v. patient-controlled analgesia (PCA) and patient-controlled epidural analgesia (PCEA), in three different conditions: rest, movement and coughing, with visual analogue scales (VAS 0 to 100). Secondary point was patient satisfaction.

Results A total of 1,292 patients were excluded. VAS results are presented in Table 1 as mean ± SD. At rest, the PCEA group is significantly better than the other two groups. When at movement, there is no difference between the PCEA group and the D/N group but significantly better than the other two groups. When at movement, the PCEA group is better than the other two groups. While coughing, the PCEA group is significantly better than the other two groups. When at movement, the PCEA group is significantly better than the other two groups. When at movement, the PCEA group is significantly better than the other two groups.

Conclusion PCEA provided better pain control at rest than the other two methods, whereas PR.N. Demerol/NSAID and PCA were somewhat better than PCA when patients were moving. While coughing, PR.N. Demerol/NSAID provided the best pain control. However, patient satisfaction was significantly better with PCEA.

Subanesthetic xenon increases erythropoietin levels in humans and remains traceable in the first 24 hours after exposure: a randomized controlled trial
J Ney, C Stoppe, M Rossaint, M Coburn
RWTH Aachen University, Aachen, Germany

Introduction The noble gas xenon was recently amended to the list of prohibited substances by the World Anti-Doping Agency as
It is supposed to trigger the production of HIF-1α and subsequently erythropoietin. Subsequently, researchers and clinicians started a scientific discussion about the potential clinical benefit in support of humans exposed to high demand, such as critically ill patients. The objective of this study was therefore to evaluate the effect of xenon on serum levels of erythropoietin in healthy volunteers.

Methods This is a monocenter, randomized, blinded, crossover trial, which was registered at ClinicalTrials.gov (NCT01285271). Healthy study test persons were spontaneously breathing randomly 1 hour of xenon 30% (Xe/O₂, 30%/65%) or control gas (N₂/O₂, 30%/65%). The primary outcome parameter was the erythropoietin level 24 hours after exposure. Secondary outcome parameters are xenon’s elimination kinetics measured in blood and exhalation samples.

Results The application of xenon increases erythropoietin levels with a maximum 24 hours after exposure (1.32 (0.99 to 1.66) \( P = 0.033 \)) compared with the baseline values and compared with control values (0.87 (0.68 to 1.05) \( P = 0.012 \), Figure 1). Xenon was gas chromatographically traceable in blood and exhalation probes up to 24 hours after exposure.

Conclusion One hour of a subanesthetic level of xenon increases erythropoietin levels in healthy study test persons and remains gas chromatographically traceable in blood and exhalation probes 24 hours after exposure. These findings may stimulate larger studies to confirm these results and to open new avenues for the therapeutic use of xenon in critically ill patients.

**MIRUS™, a new system for sedation with halogenates in the ICU: a preliminary study of feasibility in postsurgical patients**

P Mancinelli, S Romagnoli, C Chelazzi, G Zagli, E Boncolini, A Belardinelli, AR De Gaudio

Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Critical Care 2015, Volume 19 Suppl 1

**Introduction** Sedation is standard practice in the ICU [1]. The aim of this study was to investigate the efficiency and safety of the MIRUS™ system (Pall Medical), a new device for sedation in ICU patients [2]. The system delivers volatile anesthetics in mechanically ventilated patients. An open reservoir scavenger and a dedicated gas filter avoid residual volatile anesthetic halogenate escaping into the room air.

**Methods** Ten mechanically ventilated patients elective admitted for ICU postoperative monitoring were sedated with sevoflurane delivered with the MIRUS™ system. Two patients were excluded from the analysis because inclusion criteria had been lost during the study period. Analgesia was obtained with morphine sulfate: bolus 0.1 mg/kg i.v. at the end of surgery and 0.2 to 0.4 mg/kg/24 hours. The primary endpoint was to achieve predefined levels of sedation (Riker scale 4). Secondary endpoints were the assessment of hemodynamic stability (MAP and HR), blood lactates, any type of side effects, and sevoflurane consumption. Data were collected at the following times: admission to the ICU (T1), 1 hour after initiation of sedation (T2), and 1 hour after sedation withdrawal (T3). Results were expressed as median (IQR) or mean (SD), where appropriate.

**Results** The local ethical board approved the protocol. Median duration of sedation was 4 (5.5 to 2) hours. Predefined levels of sedation were achieved in all patients with a median MAC of sevoflurane of 0.5 (0.5 to 0.3)% and with a median gas consumption of 9.9 (14.3 to 5.3) ml/hour. MAP and HR values at T1 were 86.5 (97 to 80.8) mmHg and 81.5 (103.8 to 65) bpm, respectively; at T2, 74.5 (89 to 69.5) mmHg and 74 (82 to 58.3) bpm, respectively; and at T3 92.5 (101 to 76.8) mmHg and 74 (88.5 to 66.3) bpm, respectively. Lactates were always normal. Mechanical ventilation was interrupted 5.4 (3.1) minutes after withdrawal of sevoflurane and respiratory parameters always were within normal values. Finally, no side effects were registered at any phase of the study.

**Conclusion** This pilot study shows that MIRUS™ is effective and safe in delivering sevoflurane for sedation at a predefined target level in postsurgical patients, without side effects. Further data with a larger number of patients and for a longer duration of sedation are required to confirm these positive, preliminary observations.

**Bispectral index-guided anesthesia on time to tracheal extubation after onpump cardiac surgery**

E Kaval, P Zeyneloglu, A Camkiran, A Sezgin, A Pirat, G Arslan

Baskent University Faculty of Medicine, Ankara, Turkey

Critical Care 2015, Volume 19 Suppl 1

**Introduction** Electroencephalographic-based cerebral monitors such as the bispectral index (BIS) have been used for titration of both inhalational and intravenous anesthetics during general anesthesia. Titrations of anesthetics using these monitors may facilitate an earlier recovery from general anesthesia and less consumption of anesthetics. The primary aim of this study was to investigate whether BIS-guided anesthesia would reduce time to tracheal extubation when compared with minimum alveolar concentration (MAC)-guided anesthesia in patients undergoing onpump cardiac surgery.

**Methods** Fifty patients undergoing elective coronary artery bypass grafting surgery from a single tertiary referral university hospital were randomized to BIS-guided anesthesia (Group BIS, \( n = 25 \)) and MAC-guided anesthesia (Group MAC, \( n = 25 \)). The inspired desflurane concentration was titrated to maintain a BIS value of 40 to 60 in Group BIS and an age adjusted minimum alveolar concentration of 0.7 to 1 was used in Group MAC. Time to tracheal extubation across the two groups was the primary outcome measure. Secondary outcomes included intraoperative desflurane consumption, postoperative complications, and lengths of stay in the ICU and hospital.

**Results** Demographic features, logistic EuroSCORE, duration of cardiopulmonary bypass and surgery were similar in both groups. Mean desflurane consumption was significantly lower in Group BIS (11.9 ± 1.7 ml/hour) compared with Group MAC (13.4 ± 3.0 ml/hour) (\( P = 0.031 \)). Time to tracheal extubation was not significantly different between the groups (13.3 ± 9.6 hours vs. 17.0 ± 22.4 hours) (\( P = 0.68 \)). Incidences of postoperative complications were similar and lengths of stay in the ICU and hospital were 2.4 ± 0.7 days versus 3.2 ± 2.7 days.
Use of sevoflurane in the medical ICU: 2-year experience, patient and safety profile
A Koralj1, A Markota2, F Svenšek2, A Sinkovič1
1University of Maribor, Slovenia; 2University Medical Centre Maribor, Slovenia

Introduction
The aim of this study is to present our experience with sevoflurane in the ICU, outcome which patients were sedated with sevoflurane and present safety profile. Sevoflurane has some potential advantages over intravenous sedation: rapid elimination and few interactions. The optimal role of sevoflurane in ICU is not known.

Methods
We performed a retrospective study on adult patients who were sedated with sevoflurane in the medical ICU. The decision to use sevoflurane was left to the attending physician. Institutional ethics committee approval was obtained. The target mean alveolar concentration in all patients was 0.5 to 1%. The AnaConDa® device (Sedana Medical, Uppsala, Sweden) was used along with the Anastasia® (Sedana Medical) gas monitor. Data were obtained from patients’ medical records.

Results
We included 61 adult patients who were admitted from April 2012 to November 2014. Mean age was 62.6 ± 14.9 years, 39 (63.9%) were male. ICU mortality was 41%, hospital mortality was 43%. Mean duration of sevoflurane use was 3.56 ± 2.31 days. Admission diagnoses were: successful resuscitation after cardiac arrest (44.2%), sepsis (37.7%), cardiogenic shock (4.9%), pancreatitis (3.3%) and liver failure, acute renal failure while receiving sevoflurane. Sevoflurane was continued in all patients and renal failure was attributed to alternative diagnoses. No alternative in all three patients. Seven (11.4%) patients developed renal failure while receiving sevoflurane. Sevoflurane was continued in all patients and renal failure was attributed to alternative diagnoses.

Conclusion
We identified sevoflurane as an appropriate sedation agent in a diverse group of patients. Sevoflurane advantages over intravenous sedation could be more pronounced in some patient groups (for example, successful resuscitation after cardiac arrest). The safety profile of sevoflurane sedation was comparable with intravenous sedation [1].

Interaction between etomidate and beta tumoral necrosis factor on hemodynamic response after cardiac surgery
JL Irribarren, JJ Jimenez, N Perez, M Brouard, R Perez, O Gonzalez, A Arbesu, R Martinez, ML Mora
Hospital Universitario de Canarias, La Laguna, Spain

Introduction
The use of etomidate is a risk factor for relative adrenal insufficiency in patients undergoing cardiopulmonary bypass (CPB) [1]. The objective was to determine the possible interaction between etomidate and beta tumoral necrosis factor on hemodynamic response after cardiac surgery.
etomidate and beta tumoral necrosis factor (TNFβ) polymorphism on hemodynamics after CPB.

Methods A prospective cohort study on CPB patients who received etomidate or not during anesthetic induction during 2008 to 2011. Demographic and postoperative variables were collected. We tested the Hardy–Weinberg equilibrium in order to avoid selection bias. V18 SPSS was used.

Results We studied 433 patients undergoing CPB. 285 (65.8%) men and 148 (34.2%) women, 66 ± 6 years, EuroSCORE I 5.3 ± 4%. TNFβ was in Hardy–Weinberg equilibrium (p: 0.6; P = 0.42). A total of 254 (58.7%) patients received etomidate, 152 out of them required vasoactive drugs. Homozygous G was defined as unfavorable TNFβ versus the A allele [2]. Using the general linear model after adjusting for sex and amines dose at 4 hours, an independent association was observed between the systemic vascular resistance index (SVRI) at 4 hours and the use of etomidate (F: 18; P <0.001): 1,849 (95% CI: 1,673 to 2,024) versus 2,493 (95% CI: 2,258 to 2,729) dinas seg/cm² m², the presence of homozygous G (F: 6.5; P = 0.01), and also showed a significant etomidate–homozygous G interaction (F: 22.8; P <0.001): 1,687 (95% CI: 1,350 to 2,023) versus 3,041 (95% CI: 2,589 to 3,492) dinas seg/cm² m² (Figure 1).

Conclusion Etomidate use is associated with lower postoperative SVRI which is increased in the presence of G homozygosity for TNFβ polymorphism.

P497 Sedation practices in South African ICUs: results of a national survey
F Paruk, S Chetty
University of Witwatersrand, Johannesburg, South Africa

Introduction There has been a paradigm shift in the approach to sedation of critically ill patients. The purpose of this study was to evaluate current sedation-related practices in South African ICUs.

Methods A validated questionnaire was distributed electronically to physician members of various medical databases in South Africa as South Africa does not have a formal registry of critical care practitioners.

Results One hundred and twenty-six of 174 respondents indicated that they practice in the ICU setting. Sixty-six per cent were specialists and mainly anaesthesiologists (42%), whilst 32% were critical care subspecialists. The public and private-sector representation was 64% and 46% respectively. A written sedation guideline is implemented by 42%. Forty-three per cent utilise a sedation scale, with the Ramsay Sedation Scale being the commonest in use. However, 38% ofsedation scale users do so infrequently. Daily interruption of sedation is practiced by 75%. Light sedation is targeted by 42% and 14% do not follow any sedation targets. Upon admission and on subsequent days, sedation targets are achieved most of the time by 48% and 69% of the respondents respectively. Whilst a wide variety of sedatives are prescribed, midazolam constitutes the most commonly prescribed agent. Dexmedetomidine is the agent of choice for postcardiac surgery patients with cardiovascular comorbidities, delirious patients, during weaning and for non-invasive ventilation. Propofol is the agent of choice amongst neurological patients. The respondents indicated that there is a need for local sedation guidelines.

Conclusion The findings are comparable with reports of sedation surveys conducted in other countries. There is an evidence–practice gap that needs to be addressed.

P498 Epidemiology of operation-related medical errors in inpatients in Japan: the JET study
Y Ohta1, M Sakuma1, D Bates2, T Morimoto1
1Hyogo College of Medicine, Hyogo, Japan; 2Bingham and Women's Hospital and Harvard Medical School, Boston, MA, USA

Introduction Operation therapy is more invasive than medication therapy and then operation-related medical errors (MEs) might be of more significant impact than medication errors. We assessed the incidence and characteristics of operation-related MEs to improve patient safety in such patients.

Methods The Japan Adverse Event (JET) study was a prospective cohort study which had evaluated AEIs and MEIs at two tertiary care hospitals. We included all adult patients aged ≥15 years old who had operations over a 2-month period. The primary outcome of this study was the operation-related MEs, defined as any deviation from appropriate process of an operation or perioperative care. Trained nurses placed at each participating hospital reviewed all charts daily on weekdays, along with laboratories, incident reports, and prescription queries to collect any potential event. They also collected the characteristics of the patients in the cohort. Some operation-related MEs are associated with operation-related AEs, which are operation-related preventable AEs. After those suspected events were collected, physician reviewers independently evaluated them and classified them as operation-related AEs, AEs, or rule violations. Physician reviewers assessed and rated operation-related AEs according to the symptom and the severity of injury.

Results This study included 389 patients with 6,624 patient-days. The median age of patients was 69 years and 224 (58%) were female. Among these 389 patients, 31 patients had 46 operation-related MEs during their hospital stay and the incidence of operation-related MEs was 12 per 100 patients. Operation-related AEs occurred in 29 patients with 43 events. The most frequent symptoms for operation-related MEs were skin (26%), bleeding (21%), and central nervous system (14%). Among 46 operation-related MEs, 43 (93%) were not intercepted, and they resulted in operation-related AEs that were considered as preventable operation-related AEs. Nine of preventable operation-related AEs (21%) were fatal or life-threatening: five were nerve injury during operation and stroke after neurosurgical operation, and one biliary peritonitis after gastrectomy and cholecystectomy, and tension pneumothorax after lung lobectomy, and two unexpected massive bleeding due to vessels injury.

Conclusion Ninety-three percent of operation-related MEs resulted in operation-related AEs and 21% of them resulted in life-threatening events. Prevention of operation-related MEs should improve the mortality of surgical patients.

P499 Visualising patients’ dynamics in the ICU and predicting mortality in real-time using big data
MK Komorowski, AF Faisal
Imperial College London, UK

Introduction As informatisation of hospitals continues to spread, increasing amounts of healthcare related data are being collected, and the ICU is no exception. Large datasets are being made available to the scientific community, and offer the potential to answer clinical questions and to develop the next generation of clinical tools. A demonstration of such a tool is presented here, built using data from the Multiparameter Intelligent Monitoring in Intensive Care II (MIMIC-II) open database.

Methods All of the adult patients who died during their stay in the ICU were included, as well as a matched cohort of patients who survived for more than 28 days after discharge. Data regarding their vital signs, laboratory tests and demographics were collected. Using Matlab, a graphical method involving principal component analysis was developed. The expected mortality was computed using the k-nearest neighbours’ method and compared with several classification algorithms (logistic regression, random forest, support vector machine, Gaussian mixture models).

Results A total of 6,084 patients were included in the analyses, adding up to more than 12 million data points. Using this multidimensional dataset, a 3D representation of the clusters of survivors and nonsurvivors was built, showing how their trajectories diverge through time. Patterns in the evolution of individuals or subgroups of patients can be identified using this approach. For example, the evolution of a new patient can be visualised, progressing through the clusters as his severity changes. His expected mortality can be predicted at any point in time, with an AUC ROC constantly above 0.85.
Conclusion Machine learning tools offer an appealing mathematical framework for modelling complex medical situations. This proof of concept demonstrates that the application of computational sciences to high-quality data such as the MIMIC-II database has the potential to lead to the development of meaningful tools which will ultimately be capable of assisting physicians in making the right decision at the right time for an individual patient. Only tight cooperation between clinicians and data scientists can help close the gap that currently separates these two worlds, for the ultimate benefit of patients.

P500 Organizational factors and patient outcomes in Brazilian ICUs: the ORCHESTRA study
M Soares1, JM Kahn2, FA Bozza3, T Lisboa4, LP Azvedo5, W Viana6, L Brauer7, PE Brasil1, DC. Angus2, JLP Salluh2
1IDOR Institute for Research and Education – IDOR, Rio De Janeiro, Brazil; 2Hospital Sírio Libanês, São Paulo, Brazil; 3Hospital Copa DOR, Rio de Janeiro, Brazil; 4Hospital São Luiz Itaim, São Paulo, Brazil; 5Hospital São Camilo, Porto Alegre, Brazil; 6Hospital Sírio Libanês, Sao Paulo, Brazil; 7Hospital Copa DOR, Rio de Janeiro, Brazil

Introduction The aim was to investigate the impact of organizational factors on patient outcomes in a large sample of Brazilian ICUs.

Methods A retrospective cohort study of 59,483 patients admitted to 78 ICUs in 51 hospitals during 2013. We retrieved demographic, clinical and outcome data from an electronic ICU quality registry (Epimed Monitor System). We surveyed ICUs using a standardized questionnaire regarding hospital and ICU structure, organization, staffing patterns, process of care, and family care policies. We used multilevel logistic regression analysis to identify characteristics associated with hospital mortality.

Results ICUs were mostly medical or medical–surgical (62.79%) and located in private hospitals (67.86%). Approximately half (40.51%) had critical care training programs. Median physician and nurse staff–bed ratios were 0.15 (IQR 0.12 to 0.19) and 0.71 (0.61 to 0.84); board-certified intensivists were present 24/7 in 16 (21%) of ICUs. Routine clinical rounds occurred in 67 (86%) and daily clinical checklists were used in 36 (46%) ICUs. Most frequently implemented protocols focused on sepsis management and VAP and CLABSI prevention. Median number of patients per center was 898 (IQR 585 to 1,715) and there were 67% medical admissions; 18% patients received mechanical ventilation (MV). Median SAPS 3 score was 41 (33 to 52) points. ICU and hospital mortality rates were 9.6% and 14.3%, respectively. Adjusting for relevant patients’ characteristics (SAPS 3 score, diagnostic admission category, chronic health status, comorbidities, MV use), case-volume and type of ICU, the ICU size (OR = 1.50 (95% CI, 1.45 to 1.95), for 11 to 20 beds; OR = 2.02 (1.46 to 2.92), for >20 beds) and ≥2 clinical protocols (OR = 0.65 (0.42 to 0.99)) were the organizational characteristics associated with mortality.

Conclusion In a large sample of Brazilian ICUs, the implementation of clinical protocols was associated with better outcomes. Conversely, mortality was higher in larger ICUs.

Acknowledgements Funded by IDOR, CNPq and FAPERJ. Endorsed by BRICNet.

Methods We conducted a prospectively identified, retrospectively gathered cohort study at two hospitals of consecutively admitted medical and surgical patients over a 6-month period. One hospital had a rapid response team (RRT) and used HEWS with a trigger of 5 while the other was undergoing implementation of the HEWS without a RRT. HEWS was calculated for each patient on the first day of admission and for the 3 days prior to inpatient arrest or death. A study investigator reviewed all events for accuracy. Our outcome of interest was a composite of inpatient cardiac arrest and hospital mortality.

Results There were 7,138 patients admitted over 6 months. We found 0.5% of patients suffered an inpatient arrest and 3.6% of patients died. Moreover, 66% of patients who died or arrested were admitted to the hospital without a RRT. Patients who arrested or died had more comorbidities defined by the Charlson Comorbidity Index (CCI) of 6.0 and 8.2 respectively compared with the general population, which had a CCI of 5.2. The median and mean HEWS at time of admission was 1 and 1.7 for the general population, 2 and 2.4 for patients who suffered an inpatient arrest and finally 3 and 3.8 for those who died. There was a rise in median HEWS from 2 to 5 in the 24 hours prior to patient arrest or death. See Figure 1.

Conclusion We found that a 2.5-fold increase in HEWS occurred 24 hours prior to critical events. Similar to previous studies, a RRT in conjunction with HEWS is the best system to reduce unanticipated adverse events. An absolute HEWS of 5 and/or a rapidly increasing HEWS should trigger rapid assessment and treatment to reduce preventable inpatient deaths and arrests.

Results We identified 332 eligible patients across all trials, of whom 37 (11%) were not White British (nWB). Analysis demonstrated consent/assent refusal being significantly associated with: nWB (14, 38%, P < 0.001), intervention trial (21, 25%, P = 0.003) and different researcher–patient ethnicities (P < 0.001). Logistic regression analysis confirmed these as independent factors (nWB OR = 4.5, 95% CI = 2.1 to 9.8, P < 0.001; interventional trial OR = 2.7, 95% CI = 1.4 to 5.2, P = 0.003; data points missing for researcher–patient ethnicity so variable excluded). Conclusion This initial study suggests that ethnicity may affect assent/consent to ICU research, with patients from different ethnicities being four times less likely to be recruited. Whilst data are incomplete for researcher–patient ethnicity, our data suggest that this may be an important factor and may influence future consent processes. We believe that the role of ethnicity warrants further investigation, not only in clinical trials but also in areas such as organ donation.

Reference

Results The planned analysis for determining the discriminatory and predictive ability of the decision tree HEWS will be conducted with area under the receiver operating characteristic curves. We will test whether the current HEWS has the appropriate sensitivity and specificity when compared with that of the decision tree score. The AUROC will be calculated for both the training set of data as well as the separate population of additional medical and surgical patients. The two scores will also be plotted along an efficiency curve, comparing the percentage of vitals that precede a critical event with the percentage of vitals that produce a EWS value greater than or equal to a given EWS value.

Conclusion Decision tree analysis methodology with real-life vital signs can produce an EWS superior to previous observational studies. Using a decision tree, especially one that composites all vitals, may show that certain vitals are more predictive of critical events than others. Data will be used to further improve our current HEWS score.

P505 Outcomes and resource use in Brazilian ICUs: results from the ORCHESTRA study
M Soares1, DC Anguiz1, JB Salluh2, AB Cavalcanti3, F Colombari4, R Costa4, E Silva4, A Japaisu2, JM Kahr3, FA Bozza1
1DIO Institute for Research and Education – IDOR, Rio de Janeiro, Brazil; 2University of Pittsburgh Medical Center, Pittsburgh, PA, USA; 3Hospital do Coracao, Sao Paulo, Brazil; 4Hospital Alemao Osvaldo Cruz, Sao Paulo, Brazil; 5Hospital Quinta D’Or, Rio de Janeiro, Brazil; 6Hospital Israelita Albert Einstein, Sao Paulo, Brazil; 7Rede Amil de Hospitais, Rio de Janeiro, Brazil

Introduction The aim was to evaluate outcomes and resource use and to investigate the association between organizational factors and efficient resource use in a large sample of Brazilian ICUs.

Methods A retrospective cohort study in 59,483 patients (medical admissions: 39,734 (67%); admitted to 78 ICUs (private hospitals, n = 67 (86%); medical or medical-surgical, n = 62 (79%) during 2013. We retrieved demographic, clinical and outcome data from an electronic ICU quality registry (Epimed Monitor System). We surveyed ICUs using a standardized questionnaire regarding hospital and ICU structure, organization, staffing patterns, process of care and family care policies. Efficient resource use was assessed by estimating standardized mortality rates (SMR) and standardized resource use (SRU) adjusted for the severity of illness according to the SAPS 3 score, as proposed by Rothen and colleagues [1].

Results The median admissions per center was 898 (IQR 585 to 1,715) and SAPS 3 score was 41 (33 to 52) points. Median ICU length of stay was 2 (1 to 5) days, and ICU and hospital mortality rates were 9.6% and 14.3%, respectively. Estimated SMR and SRU were 0.97 (0.72 to 1.15) and 1.06 (0.89 to 1.37), respectively. There were 28 (36%) most efficient (ICUs with both SMR and SRU <median), 28 (36%) least efficient (ICUs with both SMR and SRU >median), 11 (14%) overachieving (ICUs with low SMR and high SRU) and 11 (14%) underachieving (ICUs with high SMR and low SRU) ICUs. Most efficient ICUs were usually located in private and accredited hospitals, with step-down units and training programs in critical care. In univariate analyses comparing most and least efficient ICUs, ≥2 clinical protocols (OR = 2.89 (0.95 to 8.72), P=0.057).

Conclusion We observed a great variability in outcome and resources in a large sample of Brazilian ICUs. Implementation of clinical protocols and nursing staffing patterns can be targets to improve the efficiency in resource use in emerging countries such as Brazil.

P506 Blood pressure and heart rate changes during shifts in ICU nurses in relation to their work experience
A Ioannidis, E Terzenidou, D Gkla va, I Politi, E Georgiadou, A Georgousi, V Aidonoudis, A KALEA, P Melitzana, N Gritsi-Gerogianni
Thessaloniki General Hospital ‘Ippokratio’, Thessaloniki, Greece

Introduction The aim of the study was to assess the blood pressure (BP) and heart rate (HR) changes during shifts in ICU nurses in relation to their work experience. Our hypothesis was that less experienced nurses, in comparison with more experienced ones, would be subjected to more work stress and this could be demonstrated by higher changes in BP and HR during shifts.

Methods We enrolled 23 nurses working in an 8-hour shift schedule at a general adult ICU. Demographic and clinical data were obtained by completing a short questionnaire. The nurses were invited to measure their BP and HR at the beginning, in the middle and at the end of their shift. An ESH/BSH-certified automatic device was used for the BP and HR measurements.

Table 1 (abstract P506). Mean change in systolic and diastolic BP and HR in relation to ICU work experience

<table>

</tbody>
</table>

Results The mean duration of working in an ICU was 7.3 ± 5.2 years (from 2 to 18 years). The nurses were grouped according to experience – Group A: 17 nurses with <10 years of experience (mean: 4.4 years), Group B: six nurses with >10 years (mean: 15.6 years). There were 640 BP–HR measurements. The mean systolic BP, diastolic BP and HR did not differ between the two groups (systolic BP: 111.2 ± 10.9 vs. 113.7 ± 14.1 mmHg, P = 0.654; diastolic BP: 72.8 ± 8.2 vs. 71.9 ± 8.1 mmHg, P = 0.835; HR: 81.4 ± 7.2 vs. 78.1 ± 8.4 bpm, P = 0.365). Nevertheless, the mean change in BP and HR during the shift did differ between the two groups, with the more experienced nurses showing a trivial reduction in systolic and diastolic BP and minor increase in HR whereas the less experienced ones showed slight increase in both BP and HR measurements (Table 1), reaching almost statistical significance. For the less experienced nurses in Group 1, it was noted that the mean changes were bigger in night shifts although the limited number of measurements did not allow robust statistical analysis.

Conclusion The less experienced ICU nurses, with <10 years of ICU work experience, tended to increase their BP and HR levels during the shift, a finding probably heightened during night shifts. Further research, including not only cardiovascular parameters, is warranted to uncover the effects of shift-work pattern in ICU nurses, taking into account this specifically stressful work environment.

P507 Prehospital transported patients: a resource for accessing prognostic risk factors
C Bech1, M Brabrand2, A Lassen1
1Odense University Hospital, Odense, Denmark; 2Sydvestjysk Sygehus Esbjerg, Denmark

Introduction The survival of patients transported by ambulance to the emergency department (ED) depends on clinical conditions, patient-related factors and organisational prehospital set up. Data and information concerning patients in the prehospital system could form a valuable resource for assessing potential risk factors associated with adverse outcomes and mortality. Our aim was to describe ambulance transports to the ED and identify prognostic factors accessible in the prehospital phase and associated with 7-day mortality.

Methods We included all adult patients (≥18 years) with a first-time ambulance transport to the ED at Odense University Hospital in the period 1 April 2012 to 30 September 2013. Ambulance personnel recorded vital signs and other clinical findings on a structured form on paper during the ambulance transport. Each contact was linked to information from population-based healthcare registers in order to identify comorbid conditions and information on mortality. Demographic factors and first registered vital sign were analysed by univariate logistic regression analysis, with 7-day mortality as outcome.

Results In total, 18,572 first-time ambulance contacts were identified in the period of inclusion. Overall 7-day mortality was 4.3% (95% CI = 4.0 to 4.6). Univariate analysis showed increasing age, Charlson Comorbidity Index ≥2, vital parameters outside the normal reference range and summoned physician-assisted mobile emergency care units to be associated with 7-day mortality. Further analyses are currently being carried out.

Conclusion We found that several prehospital-registered vital signs recorded by ambulance personnel at first contact with the patient were prognostic factors of 7-day mortality.
P508
Contribution of medical senior house officers to a medical referral in the emergency department
GF Fitzpatrick
University Hospital, Limerick, Ireland

Introduction In Irish hospitals, the medical senior house officer (SHO) is the most junior fully qualified doctor on the medical on-call team. After a patient has been seen by an emergency department doctor of any level, they are almost always referred directly to the medical SHO. This process has been shown to delay a patient’s ward admission by 3 hours 30 minutes [1]. We attempted to quantify the additional benefit for the patient of being seen by the on-call medical SHO, in terms of patients discharged, new diagnoses reached, and new treatments initiated.

Methods The emergency department notes and clinical charts of 182 patients were assessed. This constituted a random sample of patients referred by emergency department doctors to the medical team on call over a 2-month period (November to December 2011).

Results Discharged: 3/182 (1.6%) of patients referred to the medical team were discharged directly by the medical SHO. Diagnosed: medical SHOs suggested a diagnosis which was different from, or additional to, the ED doctor in 52/182 cases (28.6%). However, the medical consultant only agreed with this diagnosis in 25 cases (13.7%). This means an incorrect new diagnosis was reached more often than not (14.9%). Treatment: the majority of cases (116/182 (63.7%)) saw no new treatment initiated by the medical SHO. Of the rest, only 31 (17%) had a new treatment initiated by the medical SHO which was continued on by the medical consultant through the admission.

Conclusion Few direct discharges, new diagnoses, or key new treatments were initiated by the medical SHO in the emergency department. A paper from our hospital shows that more patients are due to transfer distances or deficiencies in the organisation of care. Additional genuine urgent OPD appointment slots could be another beneficial measure.

Achieving a time to first consultant review of under 12 hours for acutely ill medical patients
B Greatorex, EC Colley
Great Western Hospital, Swindon, UK

Introduction In 2007, the Acute Medicine Task Force made recommendations about the operation and staffing of acute medical units (AMU). Consultant-led care was seen as critical to ensuring high standards of care for patients and maintaining efficient patient flow [1]. It also recommended that during the hours when the AMU is staffed by a consultant, all patients should be seen within 6 to 8 hours. Patients admitted overnight should have a consultant review within 12 to 14 hours. Following the introduction of a 4:00 pm consultant ward round of newly admitted acute medical patients to the existing 8:00 am and 2:00 pm rounds, it was our intention to establish whether our trust was meeting those recommendations.

Methods We conducted a prospective survey of all new acute medical admissions over a 2-week period. Data collected included date and time of admission to the hospital, location on arrival, time of first medical clerking, and time of first consultant review.

Results Data were collected for 420 admissions. Sixty-seven percent of patients were admitted to the hospital between 12:00 am and 12:00 pm with a peak occurring between 4:00 pm and 6:00 pm. Sixty-two percent of patients were first seen by a consultant within 12 hours of admission, with a range from 23 minutes to 26 hours. When looking at patients admitted during the weekdays, 63% of them were seen within 12 hours; for those admitted at the weekend the figure was 57%.

Conclusion In 2011 the Royal College of Physicians emphasized the impact that the quality of the care provided within the first 48 to 72 hours had on clinical outcomes. An evaluation of consultant input into acute admissions management revealed that hospitals in which two or more ward rounds of all acute medical unit patients were performed daily had a lower adjusted case fatality rate for patients with hospital stays over 7 days. Despite twice-daily consultant ward rounds of all new acute admissions and the addition of a third 4:00 pm round from Monday to Friday, only 62% of patients were seen by a consultant within 12 hours. With 67% of patients being admitted between the hours of 12:00 am and 12:00 pm, it is possible that the substitution of an evening round for one of the afternoon rounds would help increase the number of patients seen within the target time frame. This would require a change in the working pattern of the acute medicine consultants.

Reference
in those patients who are discharged out of hours is nearly twice that of those discharged during the day [1]. These results have been replicated in our institution with a mortality of 8.7% (discharged 22:00 to 06:59) versus 4.8% (discharged 07:00 to 21:59). In the UK, NICE CG50 advised that transfer from critical care to the ward out of hours should be avoided and documented as an adverse event. We postulated that one important factor in our hospital is the decreased medical and nursing cover overnight and so looked at the delay from discharge to first medical review and to outreach review.

Methods The case notes of 100 consecutive patients discharged to the ward between September 2013 and October 2013 were examined to identify the time of discharge from the ICU and the subsequent first review by the receiving medical team and the Critical Care Outreach team. The grade of the doctor reviewing the patient was recorded.

Results Of these 100 patients, 22 were discharged between 22:00 and 07:59. From the 100 case notes requested, only 50 were available for examination. Forty patients were discharged to the wards, with only 37 having further documented medical reviews in the notes. Only 62% of patients were reviewed by a consultant following intensive care, with over 20% of patients waiting more than 24 hours for any medical review. During this time 18% of patients received a review by the nurse-led outreach team. See Figure 1.

Conclusion It is clear that a highly vulnerable group of patients who are recovering from critical illness [2] receive inadequate early follow-up within the hospital. We postulate that the delay in medical review and the lack of senior review may be caused by over 40% being discharged overnight and contribute to the increased mortality seen in our institution and the ANZICS study [1] with nighttime discharges.

Evaluation of patients with wild mushroom poisoning in the emergency department
M Altuntas, L Duran, T Yardan, H Akdemir
Ondokuz Mayis University School of Medicine, Samsun, Turkey

Introduction Wild mushroom poisoning (MP) is an important medical emergency that may have bad clinical outcome. We aimed to evaluate the clinical and laboratory features of patients with wild MP admitted to our emergency department in the Central Black Sea Region and to inform the emergency department physicians about early diagnosis and management of wild MP in the light of obtained data.

Methods This study was designed retrospectively by examining files of the patients with wild MP who were admitted to Ondokuz Mayis University Emergency Department, between January 2008 and December 2012. Patients older than 18 years were included in the study. Patients were evaluated according to gender, age, location, duration between mushroom intake and the start of clinical symptoms, time of application to hospital, clinical features and findings and treatment method. The number of patients has been compared with the regional distribution of population, monthly temperature and average annual rainfall.

Introduction Discharge from intensive care is a potentially vulnerable time for patients who are recovering from critical illness. Recent data from the ANZICS group have highlighted that the mortality difference
Results A total of 420 patients poisoned by wild mushrooms were studied. The male/female ratio was 1.5:1. The age of patients changed from 18 to 92 and mean age was 46 years. MP constituted 13.3% of all intoxication cases. The time when the first symptom occurred after mushroom intake was a mean 2 (0.17 to 2.15) hours. Of the patients, 47.6% lived in villages, 38.6% in towns and 13.8% in city centers. Admissions were mostly made in autumn, with 57.6%. Eighty-six percent of intoxications happened because of wild mushrooms collected in nature. The most frequent symptoms were nausea (93.8%), vomiting (87.1%), Increase in liver function tests in 47 patients was observed. Two of these patients died while 10 patients were transferred to further centers for liver transplantation. The remaining patients were discharged from the hospital. Conclusion Wild MP can cause bad clinical outcome. The public should be informed about the probable hazards of wild mushroom ingestion because collection and consumption of wild mushrooms from nature is common. Public health units should take protective precautions against wild MP. Education of health personals regarding MP will lead to successful results in patient management.

Time after drug overdose: effect of the introduction of a medical psychiatry unit on the allocation of ICU beds.

D Kleinloog, F Braam Houckgeest, D Sierink
Tergooiziekenhuizen, Hilversum, the Netherlands

Introduction Many patients with drug overdose are sedated, but do not make medical reasons to warrant ICU admission. Historically, monitoring behavior and suicide risk was done in the ICU, until the patient was awake enough for psychiatric consultation.

Methods A medical psychiatry unit (MPU) was instituted as part of the Department of Clinical Psychiatry. For all patients with drug overdose in the emergency department, a risk assessment was made by the psychiatrist. Those without ICU indication (such as cardiac or respiratory monitoring) were admitted to the MPU. Alternatively, when awake enough, they were seen by the psychiatrist immediately. We performed an analysis of all patients with drug overdose, admitted to our ICU (before MPU n = 88, after MPU n = 191). We used the Welch t test for comparisons.

Results After institution of the MPU, there was a 28% reduction in the number of patients with drug overdose per month, admitted to the ICU. Also, patients admitted to the ICU were sicker and stayed longer (see Table 1). There were no patients admitted to the ICU after initial MPU admission.

Table 1 (abstract P513). Patient numbers and disease severity before and after introduction of MPU

<table>

Conclusion Introduction of an MPU was associated with reduced numbers of patients with drug overdose admitted to the ICU. Those admitted to the ICU after the institution of the MPU were sicker, probably indicating more appropriate use of ICU beds.

P514

Prospective controlled study to compare the effects of a basic patient safety course on healthcare worker patient safety culture.

L Ling, G Joynt, A Lee, W Samy, H Fung, CD Gomersall
The Chinese University of Hong Kong, Shatin, Hong Kong

Introduction It is estimated that about one in 10 patients may be harmed by adverse events during their hospital stay [1]. Transforming organizational culture to improve patient safety culture is considered important. We conducted a prospective, controlled study to assess the impact of a standardized patient safety course on an ICU's patient safety culture, using a validated patient safety culture assessment tool.

Methods Staff from two ICUs – ICU1 (tertiary referral hospital) and ICU2 (district hospital) – in Hong Kong were recruited to compare changes in the measured safety culture before and after a patient safety course. The BASIC Patient Safety course was only administered to staff from ICU1, and safety culture was assessed in both units before and after, using a survey based on the Hospital Survey on Patient Safety Culture (2). Relative risk (95% CI) of improvement: baseline to follow-up in hospitals in patient safety domains, adjusted for duration of work in the unit (<10 years vs. >10 years), was calculated. Responses were coded according to the Survey User’s Guide, and positive response percentages for each patient safety domain were compared with the 2012 Agency for Healthcare Research and Quality (AHRQ) ICU sample of 36,120 respondents.

Results Preintervention and postintervention period response rates for ICU1 were 88.1% (37/42) and 79.3% (23/29); and for ICU2 63% (20/32) and 63% (15/24). Post intervention, compared with ICU2, ICU1 showed significantly improved perceptions of teamwork within the hospital unit, RR (95% CI for difference between ICUs) 1.55 (1.10 to 2.19, P = 0.01); and overall perception of safety, 1.94 (1.11 to 3.37, P = 0.02); but not increased frequency of reporting mistakes, 0.90 (0.33 to 2.49, P = 0.84). Overall, ICU1 demonstrated a greater improvement in positive responses in five safety culture domains than staff from ICU2. Patient safety culture indices were generally poorer in the two ICUs than the average ICU in the AHRQ database.

Conclusion The study provides supportive evidence that a structured, reproducible short course on patient safety is associated with a general improvement in the ICU’s patient safety culture, measured with a validated safety culture assessment tool.

Audit of imaging documentation on an ICU.

N Anora, SJ Glover
Good Hope Hospital, Sutton Coldfield, UK

Introduction The Ionising Radiation (Medical Exposure) Regulations 2001 recommend to ‘ensure that a clinical evaluation of the outcome of each medical exposure is recorded’ [1]. This audit looked at whether ICU documentation of investigations involving ionising radiation could be improved. Anticipated benefits would be improved communication between the multidisciplinary team and better-informed decision-making.

Methods Patients admitted to the ICU between 21 September 2014 and 2 October 2014 were included. If an investigation did not involve ionising radiation or was not requested by intensive care clinicians it was excluded. The indication for imaging was noted, and patient notes were analysed no less than 48 hours after the imaging was reported.
Results As shown in Figure 1, imaging requests were generally poorly documented (61%). In total, 17/26 (65%) chest X-rays (CXR)s were documented. A total of 0/2 CT scans were documented, despite one showing acute changes. In total, 17/20 (85%) CXRs requested following procedures carried out on ITU (such as insertion of central venous catheters) were documented, and the three not documented had no significant findings. The six other CXRs were requested to investigate worsening respiratory function. None were documented. Five had significant findings.

Conclusion Investigations following procedures were generally well documented, but investigations seeking pathology were not documented at all, regardless of the findings. This may have influenced the management of the patient and compromised patient safety. As such, the audit was presented at a departmental meeting to emphasise the importance of imaging documentation. A place for investigations was added to the ICU patient list to improve communication between the team, and a second audit is planned to assess the impact of this.

Barriers to the implementation of checklists in the ICU: a survey on the perceptions of 314 Brazilian critical care nurses and physicians
J Salihu, W Viana1, F Machado1, A Cavallanti1, F Bozza1, M Soares1,1IDOR, Rio de Janeiro, Brazil; 2Hospital Copa D’OR, Rio de Janeiro, Brazil; 3UNIFESP, São Paulo, Brazil; 4Hecol, São Paulo, Brazil

Introduction Checklists have been used increasingly in the ICU aiming at mitigating avoidable adverse events, but their content is variable and little is known about barriers to their full implementation. This survey reported practices on the use of checklists and perceptions regarding barriers on its implementation.

Methods A web-based survey was conducted among a convenience sample of Brazilian ICU nurses and physicians between August and October 2014. Standard descriptive statistics were used.

Results A total of 314 professionals, 104 nurses (33.1%) and 210 physicians (66.9%), responded. The majority (82.4%) had more than 5 years of experience in intensive care. Checklists were applied every day, including weekends, in only 49.8% (n = 227). When we compared the barriers perceived by those working in smaller versus larger ICUs (<10 beds vs. >20 beds), the absence of a more comprehensive checklist content (93.6% vs. 81.9%, P = 0.026), the absence of specialized software or app (80.8% vs. 63.8%, P = 0.014), low availability of mobile devices (87.2% vs. 72.4%, P = 0.019), Internet unavailability (83.3% vs. 67.6%, P = 0.017), and the limited number of computers (88.5% vs. 76.2%, P = 0.0366) were the most often barriers to implementation. Checklists were applied with similar frequencies (<3 times a week, three to five times a week, and every day, including on weekends, P >0.05) regardless of the ICU size. When the type of tool used (paper vs. electronic) was considered, the main barrier highlighted was the lack of 100% Internet availability in the ICU (64.8% vs. 100%, P = 0.009). Users of paper form had higher demands for more standardized forms and experienced more barriers to team adherence (98.1% vs. 86.4%, respectively, P = 0.034) as compared with those using specialized software.

Conclusion Although checklists are recognized as valuable tools for the adherence to best practice in the ICU, it is difficult to ensure the uniformity of their daily use. Resource limitations in smaller ICUs and the absence of comprehensive digital tools, mobile devices and Internet availability preclude full compliance at the bedside.

After Round Comprehensive Plan Summary tool: an efficiency approach for the ICU
R Markanner, M Mostafa, A Shafei, H Hon, R Ashraf, P Sreedhara, N Syed, D Ghairebeh, A Tahap, M Mostafa, A Shafei, H Hon, R Ashraf, P Sreedhara, N Syed, D Ghairebeh, A Tahap
Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates

Introduction ICU workflow for physicians, nurses and other healthcare providers is often complicated by distractions, interruptions, difficulties to concentrate, multitasking and the need to frequently change priorities in patient care-related procedures. It is therefore a continuous challenge to communicate and implement plans in an early, efficient and reliable way within the team and to constantly keep track about tasks that are completed, postponed or that are about to be forgotten. To facilitate every caregiver’s workflow and to early and efficiently communicate, we implemented the After Round Comprehensive Plan Summary (ARCoPS) tool.

Methods Most of our patient care-related therapeutic and diagnostic decisions are made during the morning round consisting of intensivists, nursing team, surgeons, respiratory therapists, dieticians, clinical pharmacists and physiotherapists. Immediately thereafter, all plans for the next 24-hour period are again discussed, summarized, confirmed, prioritized and organized by the multidisciplinary team under aspects of optimal patient care and workflow efficiency by entering the plan data into a flat screen visualized template connected to our intranet immediately accessible at every physician and nursing caregiver workstation.

Results Twelve months after implementation of the ARCoPS tool we conducted caregiver interviews and identified the following effects: increase in treatment confidence through standardized multidisciplinary decision-making; reduced loss of information through immediate plan summarization by the whole team; reduction of ambiguity and misunderstanding about care plans through early written documentation; higher level of security not to forget procedures or tasks; positive acceptance of the tool to flexibly change priorities of care procedures; positive acceptance of the tool to mark accomplished tasks providing visual feedback about the care plan status; individual caregiver workflow economization through permanent treatment plan availability; and higher job satisfaction throughout the caregiver team.

Conclusion ARCoPS tool utilization has become a daily routine in our ICU. It functions as an effective communication and workflow tool and has helped us to reduce patient care-related misunderstandings and delays. It also enhanced the economics of our work sequence, which also highly contributes to a better level of patient safety. Furthermore, it has markedly contributed to an improved level of quality of work for caregivers.

PS18
Multicenter Thai university-based surgical ICU study (Thai-SICU study): adverse events and outcome in the SICU
S Kongpayreepong, K Chittawatanarat
Siriraj Hospital, Mahidol University, Bangkok, Thailand

Introduction The aim of this Thai-SICU was to study the incidence and outcome of adverse events in nine SICU university-based hospitals in Thailand.

Methods This multicenter prospective observational study was done in >18 years old, admission >6 hours surgical patients admitted to the large, postgraduate medical training university-based SICU during April 2011 to January 2012. Patient data were divided into three main phases as admission, discharge data and daily CRFs during the ICU stay. The patients were followed until they were discharged from the ICU or up to 28 days of their ICU admission and up to 28 days following discharge from the ICU if they survived.

Results Following a 19.7-month recruitment period, a total of 4,654 patients (17,579 ICU-days) were included in the analysis process. Admitted patients had the median age of 64 years. Most of the patients were admitted directly from the OR for postoperative monitoring with median APACHE II score 10, 23% were admitted with priority I who needed aggressive hemodynamic resuscitation and respiratory support. ICU mortality and 28-day mortality were 9.6% and 13.80%. Each day of ICU increment was associated with a 1.38-day increase of hospital stay (95% CI, 1.24 to 1.53; P <0.01). On the surveillance periods, the six most common adverse events were sepsis (19.5%), AKI (16.9%), new cardiac arrhythmias (6.17%), respiratory failure (5.83%), cardiac arrest (4.86%) and delirium (3.5%) respectively. The other events including unplanned extubation within 72 hours, intraabdominal hypertension, acute MI, unplanned extubation, upper GI hemorrhage, pneumomediastinum, seizure, drug error and pulmonary aspiration were <3% each. The risk
of adverse events on 28-day mortality were significant on cardiac arrest (RR = 9.45; P < 0.01), ARDS (RR = 4.58; P < 0.01), AKI (RR = 4.18; P < 0.01), sepsis (RR = 3.62; P < 0.01), iatrogenic pneumomediastinum (RR = 3.23; P < 0.01), seizure (RR = 3.12; P < 0.01), upper GI hemorrhage (RR = 2.97; P < 0.01), cardiac arrhythmia (RR = 2.91; P < 0.01), ALI (RR = 2.71; P < 0.01), delirium (RR = 2.13; P < 0.01), MI (RR = 2.12; P < 0.01), unplanned extubation (RR = 2.06; P < 0.01), abdominal hypertension (RR = 1.75; P < 0.01) and reintubation within 72 hours (RR = 1.51; P = 0.02).

Conclusion This is the largest systemic surveillance observation in the ICU. The study results are the reference for future research and also provide information for patient and relative advice when confronted with adverse events during SICU admission.

P519
Retrospective observational cohort study of mortality and length of stay for surgical ICU admissions
M Hameed1, M Maruthappu2, D Marshall3, M Pimentel1, L Celi4, M Maruthappu5, D Marshall6, M Pimentel7, L Celi8, J Salciccioli3, J Shalhoub6
1University of Oxford, UK; 2National Institute for Health and Care Excellence, London, UK; 3Imperial College London, UK; 4Massachusetts Institute of Technology, Cambridge, MA, USA

Introduction A significant number require a postoperative ICU stay which may be prolonged [1]. Very limited data exist to characterise mortality and ICU length of stay (LOS) in different surgical specialties [2,3]. We aim to describe this relationship in a large cohort of surgical patients.

Methods We performed a retrospective observational cohort study of adult surgical admissions to the ICU of a large academic tertiary medical centre. The primary endpoint was 28-day mortality. We used simple descriptive statistics to characterise the population. The Wilcoxon rank-sum test or Kruskall–Wallis test was used, as appropriate, for tests of continuous data.

Results There were 6,203 surgical admissions during the 8-year study period. For both ICU and in-hospital mortality; the median LOS in days for survivors was 2.2 (IQR: 1.2 to 4.9) and that of nonsurvivors was 3.2 (IQR: 1.5 to 7.9). At 28 days, 1 year, and 2 years, the respective values were 2.2 (1.2 to 4.9) and 3.3 (1.5 to 6.7), 2.1 (1.2 to 4.7) and 3.1 (1.5 to 7.3); and 2.1 (1.2 to 4.6) and 3.0 (1.5 to 7.0), all P < 0.0001. The greatest median LOS was found in neurosurgery and cardiothoracic surgery; 3.3 days (IQR: 1.7 to 9.5) and 3.1 days (IQR: 1.5 to 8.0) respectively. They corresponded to the specialties with the greatest percentage ICU (9.7% and 10.2%) and 2-year mortality (27.9%, and 35%). The greatest mortality and median LOS was found in ventilicustomosis cases; 40.8% at 2 years and 10.6 days (IQR: 4.8 to 18.2).

Conclusion There is an association between postoperative ICU LOS and mortality that persists for at least 2 years after admission. Neurosurgery and cardiothoracic surgery patients appear to have a worse prognosis and also a more prolonged LOS. Our results may provide a more objective basis for clinical decisions, the use of limited resources, and inform on appropriate expectations of treatment.

Implementation of a horizontal intensive care team can impact efficiency in an emergency observation unit in Brazil
S Ribeiro, C Pettrini, L Marino, R Brandao-Neto
Hospital das Clínicas School of Medicine, University of São Paulo, Brazil

Introduction Emergency department observation units are often used to monitor critical patients in a situation of constant emergency department overcrowding and lack of intensive care beds. However, those units are often understaffed and might not have enough personnel and equipment to provide the same quality of care as a conventional ICU.

Methods We performed an observational study in a 17-bed, mixed clinical and surgical emergency department observation. Before the year 2012, the staff were composed of first-year internal medicine and surgical residents. There were no senior physicians specifically assigned to this unit, and residents were supervised by the members of the emergency department team, who changed shifts on a daily basis. In February 2012, two senior physicians (one cardiologist and one intensive care doctor) were specifically assigned to supervise the internal medicine residents and provide horizontal care for medical patients during the day, from Monday to Friday. There was no change in the presence of the surgical staff in that unit during the study period. The staff of for nights and weekends remained unchanged. Mortality and length of stay for medical and surgical patients were measured in 2011, 2012 and 2013.

Results In the first year after the implementation of the clinic intensive care team, mortality in internal medicine patients decreased from 47% to 34% in 2012 and 33% in 2013. Although other changes happened in this period (the number of beds decreased from 24 to 17, nurses and physical therapists were hired and trained specifically for this unit), we believe the horizontal team was critical, because mortality between surgical patients remained almost unchanged in the same period of time (23% in 2011, 22% in 2012 and 23% in 2013), in spite of the structural improvements that equally affected those patients. Length of stay decreased from 6.35 days in 2011 to 3.43 in 2012 and 3.15 in 2013 in medical patients and from 3.9 days on average in 2011 to 3.2 in 2012 and 2.8 in 2013 in surgical patients.

Conclusion Emergency department observation units are an alternative to alleviate emergency room overcrowding when there are no intensive care beds available. However, patients end up staying in those units for days and horizontal care by senior doctors may improve outcomes.

Rejection for ICU admission: analysis and results of this modality of limitation of therapeutic effort
F Acosta, O Moreno, M Muñoz, R Fernandez, M Colmenero
Hospital Universitario San Cecilio, Granada, Spain

Introduction The aim was to know the frequency, criteria and implications of rejection for ICU admission to our ICU unit, a second-level hospital (18 beds).

Methods An observational retrospective study in a time interval of 6 months (January to June 2013). We retrospectively registered all patients rejected for admission to our unit, analyzing the clinical and surgical emergency department observation. From the report we extracted different variables: demographical (age, sex), provenance (emergency room, hospital), clinical (comorbidity, functional situation, diagnosis, reason of requesting admission), rejection motive (‘too good’, ‘too bad; futility, lack of beds, patient rejection), whether it was definitive or conditional, whether the patient was admitted afterwards, and the state at hospital discharge. We realized a descriptive analysis (frequencies) and multivariant analysis of the factors related to futility rejection.

Results There were 165 rejections, which represents 25% of total ICU patients evaluated for admission. A total of 59.4% were male. Mean age was 69 ± 7 years (19 to 98). In total, 53.9% had more than two comorbidities (pluripathological) and 31.5% moderate to severe functional disability. The cause of rejection was in 55.2% of situations that the patient was ‘too good’; 37.6% related to qualitative futility, 4.8% was ‘too bad’ and in 1.2% a mix of lack of space (beds) and patient rejection. In the multivariant analysis the significant variables related to futility rejection were age (by years) with an OR of 1.05 (1.02 to 1.08), severe functional disability, OR of 4.35 (2.09 to 9.06), and the hospital provenance with an OR of 2.82 (1.1 to 7.2).

Conclusion Rejection for admission to ICU units is a frequent medical activity in our day-to-day job. The type of patient most rejected is cardiologic, mostly evaluated for thoracic pain probably ischemic but with low risk. In second place we found patients for which we decide rejection based on subjective qualitative futility, related mostly to age, prior functional disability and provenance.
Introduction Evidence suggests that age, chronic health status and acute illness severity affect the decision-making of clinicians regarding admission to the ICU (ITU) [1-3]. This prospective service review assesses the impact of age, APACHE II score and WHO functional score towards admission acceptance or refusal to ITU in a tertiary-level facility. Methods Design: a planned prospective review of all referrals over a 14-day period. Data collection: review (LT, DP, SP) of case notes of patients referred to ITU with the following variables collected: age, sex, APACHE II scores, WHO functional status score, grade of referer and source of referral. Data were collected on 37 patients: 22 accepted to ITU and 15 refused admission. Statistics: data were analyzed using GraphPad 6.05. Categorical variables were expressed as mean and standard error of mean. For unpaired variables, statistical significance is determined using unpaired t test. P <0.05 is considered statistically significant. Results The WHO functional status was the most significant variable affecting admission (P <0.001). The APACHE score of patients admitted to ITU was significantly lower than refused patients (P = 0.039). Patient age did not affect admission status (P = 0.15). See Table 1.

Conclusion This study was performed to assess decision-making for admission to the ITU in times of increased demand and limited availability. We want to validate our findings from this short pilot study in a larger prospective study. Multivariate regression analysis will be used to identify significant features that affect clinician decision-making in critical care admission.

Lean Six Sigma handoff process between operating room and pediatric ICU: improvement in patient safety, efficiency and effectiveness

SJ Gleich, ME Nemergerut, AA Stans, DT Haile, PA Feigal, AL Heinrich, CL Bosl, JW Ward, S Tripathi
Mayo Clinic, Rochester, MN, USA

Introduction This Six Sigma project was initiated to evaluate and improve the transfer of care of patients from the OR to the ICU. Medical errors are responsible for billions of dollars in increased healthcare spending. Miscommunication among healthcare providers is a major contributor to these errors, with handoffs a particularly vulnerable period in the care process. At our institution, surgical patients with scheduled admissions to the ICU are first recovered in the postanesthesia care unit (PACU). It was possible to develop a set of interventions based on consensus and evidence that could be applied in this complex setting. These included a handoff bundle, an operational touch-base, a unit-level safety briefing, a unit-level safety check, a lean rounding bundle and board rounds. These core interventions were supported by several more detailed resources describing the evidence base around handoff and rounding practices; and a feedback document that described all outputs and recommendations from the ICARUS project. A pilot PDSA cycle demonstrated a 55.3% and 76.3% improvement in key information transfer using a safety briefing and board round summary.

Adverse events in patients in a Brazilian intensive care unit according to readmission
GM Plantier1, CE Bosso2, AC Correa1, BHI Azevedo1, JS Alves1, CD Monteiro1, SV Ferreira1, GE Valerio1, JV Morais3, V Paso3
1Instituto do Coração de Presidente Prudente, Brazil; 2Santa Casa de Presidente Prudente, Brazil; 3Faculdade de Medicina – UNOESTE, Presidente Prudente, Brazil

Introduction Security policies for the patient are of interest to any health professional. The rates of adverse events in hospitals reach values ranging between 3.7 and 16.6%, being the highest range (40 to 70%) considered preventable or avoidable [1]. The objective of this study is to assess the prevalence and types of adverse effects in intensive care patients according to readmission.

Methods During 4 years the data from 2,562 patients admitted to the coronary ICU (CICU) were analyzed in the coronary care unit of the city of Presidente Prudente, Brazil. We analyzed the rate of readmissions, length of stay and the mainly detected adverse events. We considered significant P < 0.05 two-tailed and confidence intervals at 95% (CI).

Results The readmission rate was 15% (n = 392), particularly among males (55% (n = 214)). A 14.3% adverse event rate was observed among the readmitted patients (9.5% among those who were not readmitted). The readmitted patients were older (median: 68.0 (95% CI: 65.7 to 67.3) vs. md: 71.0 (95% CI: 67.1 to 71.3); P < 0.05) and remained hospitalized for a longer period of time (md: 5.0 (95% CI: 13.2 to 20.7) vs. md: 11.0 (95% CI: 17.0 to 33.2); P < 0.05), but not necessarily in the CICU (P = 106). The most prevalent adverse events in readmitted patients were pressure ulcers (n = 16 (4.1%)), drug administration error (n = 13 (3.3%)) and enteral feeding tube (n = 10 (2.6%)). Meanwhile, among the non-readmitted, phlebitis due to peripheral vein access and pressure ulcers (n = 42 (1.9%)), drug administration error (n = 41 (1.9%)) and enteral feeding tube (n = 31 (1.4%)). There was a tendency (P = 0.71) that readmitted patients were presented with higher prevalence of pressure ulcers (n = 16 (4.1%)) vs. n = 42 (1.9%).

Conclusion There is a higher prevalence of adverse events in readmitted patients with similarity in the type of adverse effects despite readmission.

Out-of-hours discharge from critical care: does it matter?
M Ahmed, G Lumley, S Nourse, A Hurding, A Thomas, M Healy
The Royal London Hospital, London, UK

Introduction The aim of this audit was to assess the clinical impact of out-of-hours (OOH) discharge from the adult critical care unit (ACCU) in a tertiary care hospital. Discharging patients from critical care OOH has been associated with both higher mortality and increased rate of readmissions [1,2]. As a result, national guidance stipulates that OOH discharges from critical care should be avoided [3].

Methods A retrospective snapshot analysis of patients was conducted at least 48 hours after discharge from the ACCU in October 2014. Patients discharged OOH (20:00 to 07:59) were compared with those discharged in hours (IH; 08:00 to 19:59). Analysis included: patient ICU APACHE II score, handover procedure, discharge, follow-up by the receiving team, appropriate and timely drug prescribing, recognising and acting upon clinical deterioration and readmission rates.

Results A total of 161 patients were discharged from the ACCU in October 2014. Of these, 46% of the patients were discharged OOH. Forty-one (of 74) OOH and 19 (of 87) IH discharges were sampled for further analysis. The baseline demographics and APACHE II score were similar between both groups. The majority of discharges were delayed (>4 hours, 90% IH vs. 93% OOH). More patients had nursing handover completed if discharged IH (88% IH vs. 61% OOH) and doctors’ summaries were less frequently completed OOH (83% OOH vs. 94.4% IH). A management plan for the ward was outlined in 94% of IH versus 65.6% of OOH discharges. Seventy-eight per cent OOH versus 95% IH patients discharged were reviewed by a doctor within 24 hours. Twenty-nine per cent OOH versus 67% IH patients discharged were reviewed by a consultant within 24 hours. Following discharge a management plan was followed in 94% of IH patients versus 44% OOH, patients had drug charts correctly charted in 100% of IH cases versus 66% OOH and missed/delayed doses were documented in 11.1% of IH cases versus 61% OOH. There was no difference between the groups in incidence of clinical deterioration and recognition and follow-up of clinical deterioration. Two patients were readmitted within 48 hours from the OOH group.

Conclusion This audit compares with current evidence suggesting harm from OOH discharge despite most discharges being delayed. Discharging patients is a complex hospital process, but focus needs to be on discharging patients IH. Therefore, areas for improvement include targeting forward flow of patients throughout the hospital, completion of handover documents IH and publication of guidance for receiving teams.

Pre-ICU length of hospital stay is a predictor of hospital but not ICU mortality
K Flavin, D Hall, G Marshall, P Zolfaghari
Royal London Hospital, London, UK

Introduction Prolonged hospital stay prior to admission to the ICU was previously shown to be independently associated with poorer outcome [1,2]. This is probably due to slow deterioration of physiological function in hospital and influenced by processes leading to critical care admission [2]. We investigated whether commonly measured severity scoring systems (Acute Physiology and Chronic Health Evaluation (APACHE) II, Intensive Care National Audit and Research Centre (ICNARC) and Sequential Organ Failure Assessment (SOFA) scores) are significantly different in patients admitted with prolonged pre-ICU hospital length of stay, and describe mortality and hospital length of stay.

Methods A retrospective analysis of prospectively collected data of all emergency admissions in the ICNARC database of a 44-bed adult critical care unit within a major trauma centre over a 2-year period. Demographic data, APACHE II score, SOFA score, ICNARC model score, mortality, and length of hospital stay prior to and after ICU admission were collected. Five groups of patients were defined as follows: those admitted to ICU within 1 week of hospitalization (group 1), within 8 to 14 days (group 2), within 15 to 21 days (group 3), within 22 to 28 days (group 4), and more than 28 days (group 5). Chi-squared and ANOVA tests were performed using the SOFA statistics package.

Results A total of 2,248 emergency admissions were analysed. The majority of patients were admitted within 1 week of hospital admission (n = 1,807). They were younger and had lower APACHE II scores (15 vs. 19; P < 0.001). APACHE II scores were the same in all other groups (groups 2 to 5). Patients admitted to the ICU 3 weeks following hospital admission had significantly higher hospital mortality (up to 50%; P < 0.001) and ICU length of stay (12 ± 15 vs. ± 8 ± 10 days; P < 0.001). ICU mortality remained the same in all groups (20 to 28%). ICNARC and SOFA scores were equal between the groups. The post-ICU lengths of stay were significantly longer in groups 3 to 5. In-hospital CPR prior to admission to ICU was lower in patients from groups 4 and 5, probably signifying appropriate DNAR decisions made on the ward.

Conclusion Prolonged pre-ICU hospital admission is associated with higher hospital but not ICU mortality. Commonly measured scores do not reflect this higher mortality in patients admitted after prolonged stay in hospital. Further research into parameters that may reflect changes in physiological reserves may strengthen these scores for such patients.

Study of the costs of an ICU according to age groups relating to SAPS 3 gravity, stay and outcomes  
MB Velasco, MA Leitão, DM Dalcomune, MB Leitão  
Hospital Meridional S.A., Cariacica, Brazil  

Introduction  Hospital costs are a constant concern within health, especially in the ICU. Hospital admissions and average life expectancy have been growing gradually mainly in older and critical patients. This study is aimed to observe the direct costs of patients admitted to an ICU and their relation to the SAPS 3, length of stay in the ICU and final outcome.

Methods  A retrospective observational study in which the direct costs were studied (materials, medicines, oxygen therapy and hospital fees) for 1,790 ICU patients from November 2013 to November 2014. The readmissions within 48 hours were excluded and also 10% of patients who had the highest and lowest costs. The remaining 1,401 patients were divided by age groups.

Results  Of the patients studied, 54.6% were male. Average age was 57.8 years (18 to 105 years). The biggest ICU average cost was in the group of patients 81 to 90 years old (US$793.00), as well as longest ICU stay (9.25 days), highest SAPS 3 (53.96) and higher ICU and in-hospital mortality (14.29% and 19.25% respectively). This study shows that the direct cost of the ICU stay for older patients was higher than for younger patients. The difference was explained by the higher severity measured by SAPS 3 in the older age groups (Figure 1), and the required greater length of stay in the ICU (Figure 2). As might be expected, the mortality in the group of older patients was also significantly higher.

Conclusion  This study showed that greater age is associated with higher severity measured by SAPS 3, higher direct costs, and higher mortality both in the ICU and in-hospital environment.

Figure 2 (abstract P528).

P530  
Critical care in a maternity hospital: a retrospective observational study  
F Kavanagh, J Browne  
National Maternity Hospital, Dublin, Ireland  

Introduction  Pregnancy and labour usually progress uneventfully; however, serious complications can occur and develop rapidly, necessitating critical care admission and support. Successive confidential enquiries have highlighted deficiencies in this area and suboptimal care leading to increased morbidity and mortality [1]. The National Maternity Hospital is the largest maternity hospital in the Republic of Ireland where a total of 8,954 babies were delivered in 2013. It is a stand-alone institution and onsite facilities include a two-bed dedicated anaesthesia lead high-dependency unit.

Methods  A retrospective observational study was carried out from January 2011 to January 2014 especially looking at the following parameters: admitting diagnosis, demographics, length of stay and the number of admissions requiring transfer for tertiary-level care.

Results  In total, 29,344 deliveries occurred. A total of 376 HDU admissions were recorded in this period, representing 1.28% of all admissions. The average age of patients admitted to the HDU was 34 years. The predominant reasons for admission were hypertensive disease of pregnancy (49.7%), haemorrhage (anteptum/post-partum) (36.4%), sepsis (4.2%) and other reasons (11.1%) including cardiac rhythm disturbances, neurological complications and pre-existing medical disease. In 2013 the average length of stay was 2 days. A total 6.1% of those admitted to HDU required transfer for tertiary-level ICU care in other centres during the study period, this represented 0.07% of all deliveries.

Conclusion  There is significant demand within our institution for HDU care for our patients, with the number of admissions increasing in 2013. The main admitting diagnoses are hypertensive disease of pregnancy and haemorrhage with an increase in the number of patients being admitted for management of sepsis in 2013. This highlights the increasing awareness, recognition and management of this condition in pregnancy. The increased number of HDU admissions in 2013 could also be explained by the recent introduction of an early warning score for the deteriorating patient in our hospital but this would require further evaluation. The low number of transfers of patients to other tertiary centres underpins the importance of an anaesthesia lead service.

Post-traumatic stress symptoms in intensive care staff working in adult and paediatric settings  
G Colville1, J Hammond1, J Perkins-Portas2  
1St George’s Hospital, London, UK; 2St George’s University of London, UK  

Introduction  The objectives of this survey were to establish the prevalence of symptoms of post-traumatic stress in mixed staff groups working in adult and paediatric intensive care settings and to examine the main themes in staff descriptions of the most traumatic event they had experienced at work.

Methods  A total of 355 health professionals working on three adult and four paediatric units at two centres were asked to rate their current level of post-traumatic stress symptoms on the Trauma Screening Questionnaire (TSQ).

Results  Paediatric/neonatal intensive care staff were more likely to score above the clinical cutoff point for post-traumatic stress symptoms on the TSQ in relation to an incident at work than adult intensive care staff in this sample (PICU n = 33/193 (17%) vs. AICU n = 13/162 (8%), P <0.001). For the 172 staff who provided a description of the most traumatic event they had experienced, the following themes were...
The type of brain damage were determined as brain damage associated with head trauma (Group HT), head trauma accompanying general body trauma (Group HT + GBT), and spontaneous haemorrhage (Group SH). The type of brain damage and type of brain damage.

Most commonly endorsed: patient death (and particularly untimely deaths on adult units); handling distressed families; and concerns about the quality of care and dealing with staff conflict (see Figure 1).

Conclusion A significant minority of staff reported clinically significant levels of post-traumatic stress related to their work. The facts that post-traumatic stress levels were higher on paediatric units despite their lower rates of mortality and that untimely deaths were frequently mentioned by adult unit staff suggest it may be that untimely deaths are particularly hard to deal with. More research is needed on the prevalence of distress in staff working in these settings.

P532 Distribution and mortality factors of cases with traumatic and nontraumatic brain damage treated in ICU
S Gokus Tomruk, N Bakan, G Karaoren, E Akcay, S Keskin
Umraniye Research and Training Hospital, Istanbul, Turkey

Introduction Cases of traumatic and nontraumatic brain damage have high rates of morbidity and mortality. In this study of cases being treated in the ICU for a diagnosis of brain damage, it was aimed to evaluate the relationship between mortality and the distribution of reason for and resulting type of brain damage and to determine other factors affecting mortality.

Methods After local ethics committee approval, a total of 1,004 patients (2012, n = 492; 2013, n = 454; 2014, n = 58) treated in the ICU in a 2-year period were reviewed. This study included for evaluation 135 patients determined with traumatic or nontraumatic brain damage, with a more than 24-hour stay in the ICU. Reasons for brain damage were determined as brain damage associated with head trauma (Group HT), head trauma accompanying general body trauma (Group HT + GBT) and spontaneous haemorrhage (Group SH). The type of brain damage was defined from the radiological diagnosis (CT and/or MRI) as subarachnoid haemorrhage, intracranial haemorrhage (ICH), subdural haematoma (SDH), epidural haematoma (EDH), skull fracture, brain contusion or a combination of these (COM). Operations were evaluated as performed by the brain surgery department.

Results The patients comprised 73.3% males and 26.7% females with a mean age of 40.58 ± 24.14 years (range, 1 to 87 years), mean APACHE II score of 19.07 ± 10.19 (range, 2 to 41), mean GCS of 9.17 ± 4.42 (range, 1 to 15) and 68.1% of whom were discharged and 31.9% were exitus. Mortality of patients admitted to the main French military intensive care unit (ICBU) of Percy Military Hospital (France) between January 2000 and December 2011. Statistical analysis was performed with R version 3.1.2. We first conducted univariate analyses with simple logistic regression, then a simple periodic auto-regressive model was applied. Results A total of 1,913 patients were admitted for acute burn injury. Mean total body surface area burned (TBSA) was 23.2% (IQR: 10 to 30) and mean full thickness total body surface area burned (FTBSA) was 13.4% (IQR: 0 to 15). Inhalation injury was present in 441 (23.1%) cases, intoxication (CO, CN) was present in 86 (4.6%) cases, and associated traumatisms also

P533 Association with amount of registration and outcome in pediatric severe trauma patients
S Ohnishi, N Saito, Y Yagi, Y Konda, Y Hara, H Matsumoto
Nippon Medical School Chiba Hokushu Hospital, Chiba, Japan

Introduction Unexpected trauma is one of the most major causes of death for children in the world. However, pediatric severe trauma patients are rare and scattered. Although there is a strong association between patient’s volume of trauma center volume and outcomes in adults, such a report is less in children. In this study, we aimed to clarify the relationship of the amount of registration and outcome in pediatric trauma patients.

Methods This retrospective study analyzed data of the Japan Trauma Data Bank from 2004 to 2012. We registered pediatric patients aged younger than 12 years with severe multiple or torso trauma (maximum Abbreviated Injury Scale score ≥3 or Injury Severity Score ≥9, and excluded patients with cardiopulmonary arrest on arrival, burn, isolated head or limb injury, lack of data). We divided the facilities into six groups according to every 10 patients registered and compared mortality between each group.

Results A total of 1,015 patients from 105 facilities were included in the study. Number of registrations: 0 to 10 patients: 673 patients/68 facilities, 11 to 20: 381/28, 21 to 30: 141/6, 31 to 40: 101/3, 41 to 50: 45/1, 51 to 60: 58/1. Victims of blunt trauma accounted for 98.1%. Median age was 7 (interquartile range: 5 to 10) years, median injury severity score (ISS) was 17 (10 to 26). Multivariate analysis adjusted for age, revised trauma score and ISS revealed that the amount of registration (every 10 patients) was independently associated with survival (odds ratio: 1.55, 95% confidence interval: 1.06 to 2.26, P = 0.023).

Conclusion There was a strong association between amount of registration and outcome.

P534 Mortality in a French military burn centre: a 12-year retrospective study analysing seasonal variations
M Boutonnet1, C Dussault2, N Donnat1, P Laissetal1, A Cirolle1, J Schaal1, C Hoffmann1, P Jaul1, T Leclerc1
1HIA Percy, Clamart, France; 2IRBA, Bretigny sur Orge, France

Introduction Factors associated with mortality in severely burned patients are well known. We aimed to assess the seasonal variations of the mortality of patients admitted to the main French military intensive care burn unit (ICBU) and to determine their relations to seasonal variations of severity or other factors (for example, staffing).

Methods We performed a retrospective study analysing the medical records of all patients admitted to the ICBU of Percy Military Hospital (France) between January 2000 and December 2011. Statistical analysis was performed with R version 3.1.2. We first conducted univariate analyses with simple logistic regression, then a simple periodic regression for seasonal variations (with and without harmonics for robustness), and finally a multivariate logistic regression with periodic terms in order to adjust seasonal variations for known severity factors.

Results A total of 1,913 patients were admitted for acute burn injury during the study period, with a male to female ratio of 2.34. Mean total body surface area burned (TBSA) was 23.2% (IQR: 10 to 30) and mean full thickness total body surface area burned (FTBSA) was 13.4% (IQR: 0 to 15). Inhalation injury was present in 441 (23.1%) cases, intoxication (CO, CN) was present in 86 (4.6%) cases, and associated traumatisms also

(P <0.01). No statistical difference was determined in mortality in terms of age, gender, duration in ICU, surgical treatment or not, or reasons for brain damage (P >0.05).
in 88 (4.6%) cases. The mortality rate was 10.9%. The following factors were associated with mortality in univariate logistic regression: age, body mass index, past medical history, TBSSA, FTBSA, intoxication (CO, CN), inhalation injury, flame burns, self-inflicted burns (all P < 0.0001), sex (P < 0.001), and admission date (P < 0.01). Simple periodic regression showed a biannual seasonal effect on mortality, documented with a 1-year periodic (P < 0.01) and a 6-month periodic (P = 0.01) dependency. Multivariate analysis with or without periodic terms identified age, past medical history, TBSSA, FTBSA, intoxication and admission date as the only factors independently associated with mortality.

Conclusion Predictive factors for mortality in our ICU are in line with the literature. The documented seasonal variations in mortality are fully explained by variations in these severity factors. Complementary analyses are under way to further study a nonlinear age effect.

Methods All of the patients enrolled in the PROWESS-SHOCK were included. Liver dysfunction at baseline was defined by a liver Sequential Organ Function Assessment (SOFA) score >0. The onset of a liver dysfunction at baseline was defined as any post-baseline increase of the hepatic SOFA score from 0. The worsening of liver dysfunction post baseline was defined as any increase of the hepatic SOFA score from the baseline assessment. The post-baseline period studied extended from study drug infusion to day 28. The main outcome was the mortality at day 180, and the secondary outcomes were the mortality at day 28 and at day 90. Cox proportional hazard models were used to estimate the hazard ratio of death.

Results Baseline liver function was assessed in 1,565 patients. Of those, 522 (33%) exhibited liver dysfunction at baseline. No relationship was found with mortality according to baseline liver dysfunction status at day 28 (HR, 0.847 (95% CI, 0.647 to 1.109); P = 0.2267), day 90 (HR, 0.883 (95% CI, 0.701 to 1.112); P = 0.2892) and day 180 (HR, 0.885 (95% CI, 0.710 to 1.103); P = 0.2761). A total of 403 (26%) patients developed a new liver dysfunction (257/1,043, 25%) or worsened liver dysfunction (146/522, 28%) in the 28-day post-baseline period. The overall median time to develop or to worsen liver dysfunction was 2 (1 to 4) days. Significant relationships between the new onset or the worsening of liver dysfunction post baseline and mortality at day 28 (HR, 1.67 (95% CI, 1.26 to 2.21); P = 0.0004), day 90 (HR, 1.65 (95% CI, 1.30 to 2.09); P < 0.0001) and day 180 (HR, 1.57 (95% CI, 1.26 to 1.97); P < 0.0001) were found.

Conclusion The new onset or the worsening of liver dysfunction during the course of septic shock impacts strongly on long-term mortality. Septic patients with liver dysfunction need long-term follow-up. Future research should focus on developing specific septic liver therapeutics and new tools for earlier detection of septic liver dysfunction.

Reference
Patients (52%) were male. Upon admission, 15 patients (5.4%) had univariate and multivariate logistic regression. The primary outcome was ICU mortality. Data were analyzed with evaluation of organ dysfunctions and need for hemodialysis, treatment toxicity and decompensation of chronic diseases. The aim of these studies was to identify factors associated with mortality in the 180 days following ICU admission and to identify predictors of death by 180 days. Our study looked at a number of factors that might reasonably be expected to be associated with short-term and long-term outcomes and identified several that were independent predictors of death by 180 days.

## P538
Is admission of hematologic malignancies in the ICU justified?

VG Gasparovic, MM Grgic Medic, IC Gornik
KBC Zagreb, Croatia

## Introduction
The admission of malignant hematology patients to the ICU is combined with poor prognosis [1]. A young population on one side and serious prognosis on the other are the main characteristics. Do we help? We are analyzing continuously clinical characteristics, treatment, and outcomes of critically ill patients with hematologic malignancies admitted to the medical ICU to identify predictors of adverse outcome [2].

## Methods
Demographic characteristics, hematologic diagnosis, reasons for ICU admission, transplant status, the presence of neutropenia, and APACHE II and SOFA scores were analyzed. Predictors of ICU mortality were evaluated using univariate analysis.

## Results
There was a total of 194 patients (103 male), APACHE II score by admission was 27 ± 8, SOFA 9 ± 3. Acute leukemia (L) in 81 patients (41.8%), chronic L in 19 patients (9.8%), lymphoma in 58 patients (29.9%), and multiple myeloma in 28 patients (14.4%) were the etiology. Respiratory insufficiency, hemodynamic instability, AKI and CNS disturbances were responsible for the admission of 169 patients (87.1%) from the hematology ward to the ICU. In total, 127 patients (59.7%) were mechanically ventilated; 93 required invasive mechanical ventilation (MV). Non-invasive ventilation started in 34 patients and was successful in 14 (6.5%). The ICU mortality rate was 104 patients (53.6%), and the mortality of MV patients was 98 (77.2%). Need for vasopressors at admission, MV, neutropenia, and APACHE II and SOFA scores were identified as independent predictors of fatal outcome. Overall mortality of admitted patients was 53.6% (104 patients), and in ventilated patients was 77.2% (98 patients).

## Conclusion
The ICU mortality of critically ill patients with HM is high, particularly in the group on MV. Different factors were independent predictors of mortality, but 46.4% of admitted patients survived because of adequate support possibilities and were transferred back to hematology ward. The ICU admission with organ support is according results important for life saving in this extremely high-risk patient group.

Outcomes of patients with hematologic malignancies admitted to the ICU

I Duayer, E Osawa, C Park, J Fukushima, J Almeida, R Nakamura, F Galas, L Hajar
Institute of Cancer of State of São Paulo, Brazil

## Introduction
In recent decades, therapeutic advances resulted in increased survival of patients with hematologic malignancies. These patients are increasingly admitted to the ICU due to infections, treatment toxicity and decompensation of chronic diseases. The aim of this study is to evaluate ICU, hospital and 6-month mortality of 169 patients with hematological malignancies admitted to the ICU and to identify predictors of ICU mortality.

## Methods
We performed a retrospective study of 277 consecutive patients with hematological malignancies admitted to the ICU of the Institute of Cancer of State of São Paulo, Brazil, from January 2010 to December 2013. Patient clinical and laboratory characteristics, evaluation of organ dysfunctions and need for hemodialysis, mechanical ventilation and vasoactive agents in the ICU were collected. The primary outcome was ICU mortality. Data were analyzed with univariate and multivariate logistic regression.

## Results
The median age of the population was 57 years and 144 patients (52%) were male. Upon admission, 15 patients (5.4%) had disease remission and 31 (11.2%) had newly diagnosed disease. The ICU mortality rate was 26%, hospital mortality was 35.7% and 6-month mortality was 55.2%. The median number of organ dysfunction was 3 (IQR 2 to 4) and respiratory failure was the leading dysfunction, being present in 209 patients (75.5%). During the ICU stay, 21 patients needed hemodialysis (8%), 69 (25%) needed mechanical ventilation, 162 (58%) used vasoactive agents and 22 (8%) had a decision for limitation of medical treatment. On univariate analysis, risk factors for hospital mortality were acute myeloid leukemia, hospital stay prior to ICU admission >4 days, number of organ dysfunction ≥2, colonization and infection by a multidrug-resistant (MDR) agent, use of mechanical ventilation, use of vasoactive agents and renal replacement therapy. Multivariate analysis revealed that renal replacement therapy (OR = 6.35 (95% CI: 1.5 to 25.92), P = 0.010), SOFA score (OR = 1.69 (95% CI: 1.38 to 2.06), P < 0.001), RDW (OR = 1.27 (95% CI: 1.11 to 1.46), P = 0.001), lactate (OR = 1.04 (95% CI: 1.02 to 1.06), P < 0.001), colonization of MDR agent (OR = 10.73 (95% CI: 2.13 to 53.96), P = 0.004) and hospital stay prior to ICU admission >4 days (OR = 4.72 (95% CI: 1.8 to 12.3), P = 0.002) were predictive factors of ICU mortality.

## Conclusion
Patients from our institution have survival rates comparable with data from the literature. Our study suggests that mortality is associated with late ICU admission and colonization of MDR bacteria.

Characteristics and outcomes of lung cancer patients requiring ventilatory support: results from a multinational study
AcToufari1, JF Tempst1, JS Saludd1, G Burghi1, C Iraza1, NPattison1, E Toban1, B Almeda1, E Azoulay2, M Soares3
1Hospital A. Michalhon Chu Grenoble, France; 2Post-graduation Program – Inst. Nacional de Cancer, Rio de Janeiro, Brazil; 3Hospital Maciel, Montevideo, Uruguay. *Institute Alexander Fleming, Buenos Aires, Argentina; Royal Brompton Hospital, London, UK; 4Hospital Clínico Universidad de Chile, Santiago, Chile; 5Hospital A.C. Camargo, São Paulo, Brazil, 6Hospital Saint Louis, Paris, France; 7OR Institute for Research and Education – IDOR, Rio de Janeiro, Brazil

Introduction
The aim was to evaluate clinical characteristics and outcomes of patients with lung cancer requiring ventilatory support. Results Out of 449 patients admitted to the ICUs, 239 (small-cell lung cancer (SCLC) = 151; non-SCLC = 208) required ventilatory support (NIV = 104; IMV = 135). Out of NIV patients, 31 (30%) were subsequently intubated for IMV. Main reasons for ventilatory support were sepsis (n = 119; among them, 102 patients had pneumonia), airway involvement by tumor (n = 79), ARDS (n = 47) and coma (n = 18). Mean SAPS II score was 54 ± 20 and median SOFA score was 7 (4 to 12) points. Hospital and 6-month mortality rates were 55% and 67%; 94 (39%) patients received treatment limitations in the ICU. Mortality according to ventilatory strategy was 56% for NIV only, 77% for IMV followed by NIV, and 70% for IMV only. In the multilevel model, adjusting for the hospital size, presence of step-down units, type of admission and treatment limitation, performance status (PS) 3 to 4 (HR = 2.25 (95% CI, 1.52 to 3.34)), metastasis (HR = 1.66 (1.18 to 2.33)) and the ventilatory strategy compared with NIV only (HR = 1.73 (1.02 to 2.92), for NIV followed by IMV; HR = 2.25 (1.51 to 3.35), for IMV only) were associated with increased mortality. Conversely, patients with sepsis had higher survival (HR = 0.67 (0.46 to 0.96)).

Conclusion
In a multinational study, 6-month survival in lung cancer patients requiring ventilatory support is better than perceived a priori. Palliative care should be preferred in patients with poor PS.

Admission to intensive care can be reliably predicted using only clinical judgment
M Brabrand
Hospital of South West Jutland, Esbjerg

Introduction
Not all patients in need of critical care arrive in clinical distress and some deteriorate after arrival. Identifying these patients early in their clinical course could potentially improve outcome. The present study was performed with the aim of assessing whether nursing and physician staff were able to identify patients in need of critical care using only clinical judgment and to compare this with the National Early Warning Score (NEWS).

Methods
This was a prospective cohort study of all adult patients with a first-time admission to a medical admission unit at a 450-bed regional teaching hospital over a 3-month period in 2010. All subspecialties of internal medicine are present as well as a level 2 ICU. Upon first contact with the patient after arrival, nursing staff and physicians were asked to report their estimation of the probability of ICU admission (0 to 100%). Survival status was extracted from the Danish Civil Registry. All administrative details (including transfers to other hospitals, wards and ICUs) were extracted from the National Patient Registry, both ensuring complete follow-up. The discriminatory power (ability to identify patients at increased risk) was estimated using area under the receiver-operating characteristics curve. Calibration (accuracy) was assessed using Hosmer-Lemeshow goodness of fit test. Data will be reported as median (range) or proportions (95% confidence interval).

Results
A total of 2,769 patients were included, median age 65 (18 to 100) years and 52% female. Thirty-day mortality was 4.5%, and 2.2% were admitted to ICU. Median time to ICU admission was 1 (0 to 70) day. Nursing staff assessed 65% and physicians 26% of admissions. NEWS could be calculated for 85%. Nursing staff had a discriminatory power of 0.865 (0.786 to 0.944) with little variation with experience. Calibration was acceptable, except for the least experienced nurses (<5 years). Physicians had a discriminatory power of 0.789 (0.641 to 0.937), with little variation with experience. Calibration was very good, regardless of experience. NEWS had a discriminatory power of 0.809 (0.727 to 0.891) and poor calibration. There was no significant difference in discriminatory power between the three assessments.

Conclusion
Both nursing staff and physicians were as good as NEWS at identifying patients at increased risk of ICU admission after admission to a medical admission unit. However, both nursing staff and physicians had better calibration (accuracy) than NEWS.

P543
Clinical characteristics in surviving and nonsurviving older patients admitted to the ICU
E Pappa, H Pavlou, M Eforakopoulou
KAT-eka General Hospital Kifisia, Athens, Greece

Introduction
In recent years the proportion of older people admitted to the ICU has increased. A variety of clinical and physiological factors are associated with outcome in these patients. The aim of this study is to determine the clinical characteristics associated with survival of ICU mechanically ventilated older patients.

Methods
We retrospectively studied 74 patients, aged >65 years, admitted to the ICU who underwent mechanical ventilation. Standard demographic, clinical, and physiologic data were recorded. We examined the significant differences in clinical characteristics between survivors and nonsurvivors using the Student t and chi-square tests.

Results
The mean age of patients studied (43 men and 31 women) was 79 ± 6.4 years. The type of admission was surgical 18%, trauma 26% and medical 57%. The ICU mortality of these patients was 57% and it was not associated with gender and cause of admission to ICU. Patients who survived had lower Charlson Comorbidity Index (P <0.05) and shorter duration of mechanical ventilation (P <0.01). The episodes of ventilation-associated pneumonia, sepsis and renal failure were less frequently in survivors (P <0.05). Also, in addition serum iron and cholesterol levels were significantly lower in nonsurvivors (P <0.01).

Conclusion
The mortality of ICU older patients is high. VAP, sepsis and renal failure are frequent complications in nonsurvivors. Pre-existing comorbidities considerably affect mortality.

Frailty predicts increased resource use and postoperative care requirements after revision hip surgery
A Panicker1, N Singatulina1, J Stubbs1, C Johnson2, RPorter3, D Bryden1
1Sheffield Teaching Hospitals, Sheffield, UK; 2Leicester Hospitals, Leicester, UK

Introduction
There is increasing demand for revision hip surgery in older patients with poor frailty. Our previously submitted work demonstrated that frailty predicts the need for medical review [1]. We reviewed patients for a further 16 months to see whether frailty impacts on care [2]. This is the largest reported study reviewing frailty and the need for organ supports and outcomes in complex orthopaedic surgery.

Methods
A retrospective note review of all patients from January 2012 to April 2014 undergoing revision hip surgery. Data collected included frailty, comorbidities, operative blood loss, anaesthetic technique and level of organ supports and patient location at 30 days.
Results A total of 389 patients with a mean age of 68.7 years were identified. Frail patients were significantly more likely to need vasopressors postoperatively (P = 0.012). Each increase in frailty score was associated with 0.16 increase in length of stay on the HDU (P = 0.025). Analysis of patient location at 30 days shows that frail patients stay in hospital longer (P = 0.00). Frail patients also bled more intraoperatively (P = 0.00 with a coefficient value of 239; that is, for every point increase in frailty, average blood loss increases by 239 ml). For each increase by unit of blood transfused, the length of stay increased by 5.3 days (P = 0.000). The use of epidural is not associated with increased need for postoperative vasopressors (P = 0.598). See Figure 1.

Conclusion Frailty is associated with increased intraoperative resource use and postoperative care requirements independent of choice of anaesthetic technique. This type of surgery should be subject to health economic analysis as demand amongst the frailer surgical population increases.

Predicting outcomes in critically ill patients in a resource-poor setting: the Rwanda Mortality Probability Model
T Twagirumugabe1, E Rivello2, R Fowler3, V Novack4, A Mueller2, W Kiviri1, V Banner-Goodspeed2, D Talmor2
1St Mary’s Hospital, London, UK; 2Imperial College Healthcare NHS Trust, London, UK; 3University of Toronto, ON, Canada; 4Ben-Gurion University of the Negev, Beer Sheva, Israel

Introduction ICU mortality prediction models provide robust tools for research and benchmarking in the developed world, but an ICU mortality prediction model has not been validated in a resource-poor setting. We sought to validate the Mortality Probability Admission Model, version III (MPMo-III) in two public ICUs in Rwanda and to develop a simplified Rwanda Mortality Probability Model (R-MPM) for use in developing countries.

Methods We prospectively collected data on 339 adult patients admitted to two ICUs in Rwanda between August 2013 and July 2014. We described demographic and presenting characteristics and outcomes. We assessed the discrimination and calibration of the MPMo-III model. Using stepwise selection, we then developed a new logistic model for mortality prediction, the R-MPM.

Results Patient median age was 34 (IQR 26 to 49) years; 48.7% were male. Mortality was 50.3%. The variables most predictive of mortality in univariate analyses were: age, sepsis within 24 hours of ICU admission, hypotension or shock at ICU admission, Glasgow Coma Scale score at ICU admission, and heart rate (beats per minute) at ICU admission. Using these five variables, the R-MPM predicted mortality with area under the curve of 0.829 and Hosmer–Lemeshow chi-square statistic of 8.881. The MPMo-III predicted mortality with area under the curve of 0.720 and Hosmer–Lemeshow chi-square statistic of 16.391, indicating that the predictive risk scores of the MPMo-III were not well calibrated to the Rwandan data.

Conclusion The MPMo-III had modest risk prediction capacity in a population of Rwandan ICU patients. The R-MPM is an alternative severity score with fewer and more accessible variables that provides better predictive power. This model needs to be validated in other ICUs.

P546
Emergency laparotomy clinical outcome according to patient characteristics, level of postoperative care and time of surgery
T Banerjee1, M Templeton2, C Gore3
1St Mary’s Hospital, London, UK; 2Imperial College Healthcare NHS Trust, London, UK; 3University of Liverpool, UK

Introduction Emergency laparotomies have poor outcomes with variable postoperative critical care provision [1-3]. All patients requiring an emergency laparotomy with an estimated risk of death of >10% should go to critical care. Time of surgery should not affect standard of care [2,4]. In advance of the National Emergency Laparotomy Audit (NELA) results [2], our objective was to see whether the level of postoperative care and time of surgery affect outcome.

Methods Retrospective data were collected across the Imperial NHS trust for all emergency laparotomies over 3 months in 2014; length of stay in days (LOS); mortality; age; ASA; surgery time and postoperative care level, that is ward (L1), high dependency (L2), or ICU (L3). Statistical tests: Mann–Whitney, Pearson correlation (PCC) and multilinear regression analysis.

Results Seventy-one patients underwent surgery. Overall mortality was 13% and 70% of patients went to a L2/3 bed. More ASA 1/2 patients went to L1 and all ASA 4/5 went to L2/3. Median (IQR) for age was 61 (44 to 67) for L1, 65 (48 to 73) for L2/3 (P = 0.11), LOS was 10 (7 to 16) for L1, 19 (12 to 57) for L2/3 (P = 0.002), and mortality (%) was 0 for L1 and 18 for L2/3. For surgery between 08:00 and 17:59, 14 went to L1, 28 to L2/3. Mortality was 5% and LOS 15 (9 to 24). Between 18:00 and 21:59, two went to L1, 10 to L2/3. Mortality was 17% and LOS 22 (8 to 34). Between 22:00 and 07:59, five went to L1, 12 to L2/3. Mortality was 29% and LOS 15 (9 to 36). ASA strongly predicted mortality (P = 0.006, PCC 0.32). There was a negative correlation between postoperative destination and mortality with all deaths happening in those who went to L2/3 (P = 0.038 and PCC –0.25); however, sicker patients may have gone here. There was a strong correlation between mortality and time of surgery, night surgery being a strong predictor of mortality (PCC 0.31, P = 0.008); LOS can be predicted by a combination of ASA, age and care level (P = 0.027); the postoperative care regression coefficient was negative (–18.04, SE 10.41) with prolonged LOS in patients admitted to L2/3, which could also be explained by illness severity.

Conclusion Trust mortality is similar to that in the Emergency Laparotomy Network audit [1]. Higher ASA patients are appropriately going to L2/3 care. Baseline health status and time of surgery are the strongest predictors of mortality in emergency laparotomy patients.

Developing a laboratory-based score to predict mortality in patients admitted to the ICU
A Iqbal1, I Welters2, R Kolunummae-Dona1, C Toh1, C Downey3
1Institute of Ageing and Chronic Disease, Liverpool, UK; 2Royal Liverpool University Hospital, Liverpool, UK; 3University of Liverpool, UK

Introduction Scoring systems can be used to predict mortality in patients admitted to the ICU. They are produced using variables that are associated with an increased risk of mortality such as patient
demographics, physiological measurements and coexisting conditions and can be used to evaluate ICU performance, to stratify patients in clinical trials and to assist in hospital and healthcare decisions such as resource allocation. The aim of the project was to determine whether a general score derived from routine laboratory parameters could be used to predict mortality rates in patients admitted to the ICU in the UK.

Methods P values were calculated using the t test, Mann–Whitney U test and chi-squared test, depending on distribution of data, in order to determine which variables were significantly different in the survivors and nonsurvivors of critical illness. Significant variables were categorised into subgroups according to medically relevant landmarks and univariate analytically by assessing the correlation with mortality. Forward logistic regression models were used to choose the parameters to include in our score. ROC curves illustrated the sensitivity and specificity of selected variables via their AUC.

Results Age, platelets, ALT and APACHE II were selected to be included in the new laboratory-based score. The AUC for the score was 0.714, which was higher than each of the individual laboratory parameters. The AUC was increased further to 0.781 by including all 14 variables (age, lactate, FiO2, urea, creatinine, ALT, APACHE II, platelet, bicarbonate, haemoglobin, pH, ionised Ca, carboxyhaemoglobin and albumin), although improvement was not considered significant as the confidence intervals of the two scores (4 and 14 variables) overlapped.

Conclusion A laboratory-based score was successfully established in ICU patients, revealing an AUC of 0.714 which is comparable with established scores in a similar population. The compilation of the variables to produce a laboratory-based score showed a greater prognostic power than individual variables. Model developers require an AUC of >0.7 to be termed useful; however, in order to be used in a clinical setting the AUC must be at least 0.75. Further research including internal and external validation studies must be performed to optimise the model before clinical implementation.

P548 Patient preferences for outcomes in critical care trials (OPTICS): preliminary results

J Muscedere1, F Lamontagne2, G Boyd3, M Herridge4, S Fleury5, T Sinuff6
1Queen’s University, Kingston, ON, Canada; 2University of Sherbrooke, QC, Canada; 3University of Toronto, ON, Canada

Introduction Although patient-centered outcomes are important to inform therapeutic choices for critically ill patients, patient preferences for outcomes in critical care studies are unknown. It is also unknown whether outcome preferences differ between researchers, decision-makers and those who have never been critically ill (citizens). The aim of the OPTICS Program is to investigate these preferences. Herein we report the preliminary results for outcomes preferences in citizens.

Methods We recruited and surveyed lay public members without a history of critical illness as to their preferences for outcomes in critical care studies. After an in-person educational session, citizens were asked to rank 11 potential critical care trial outcomes in order of personal preference. Each outcome was also rated for importance on a 7-point Likert scale. Participants were then asked to indicate their agreement with potential tradeoffs between potential outcomes.

Results The in-person session was attended by 31 citizens whose had a mean age (SD) of 71.6 (5.9) years and 1.5 (1.4) chronic health conditions; 25 (81%) had partially or fully completed post-secondary school education. Of the 11 potential outcomes, the three outcomes ranked highest of importance were: permanent brain dysfunction, quality of life, and requirement for long-term institutional care. The three outcomes ranked least of importance were: duration of hospitalization, death after a prolonged illness, and occurrence of delirium. When rated on a 7-point Likert scale the results were similar. Of the participants, 24/27 (89%) indicated that they would be willing to receive a therapy which was associated with a higher mortality rate but resulted in an improved quality of life in survivors. Conversely, 16/27 (59%) indicated that they would not be willing to receive a therapy which increased the chances of survival but was associated with a reduced quality of life in the survivors.

Conclusion The citizens surveyed valued outcomes associated with quality of life and intact neurological function. Mortality and other indices of duration of critical illness were valued less. These preferences need to be confirmed in larger groups with greater diversity. Future research also needs to further understand these outcome preferences in survivors of critical illness, clinicians, decision-makers, and researchers. Understanding the outcome preferences of pertinent stakeholders and whether these preferences are congruent is imperative to inform the design of future critical care trials.

P549 Disturbed circadian rhythm in ICU patients as indicated by melatonin levels: a prospective pilot study

K Kiss1, I Foldesi1, L Kemeny7, V Cermeus8, Z Molnár2, J Singer2
1University of Szeged, Hungary; 2University of Pécs, Hungary; 3Hungarian Society for Clinical Biostatistics, Hungary

Introduction The aim of this prospective pilot study was to test how melatonin levels follow the circadian cycle in ICU patients. There is strong evidence that changes of circadian rhythm are reflected in melatonin levels with peak levels at dawn and low levels during daytime[1]. The ICU stay is accompanied by disturbed circadian rhythm[2], which could potentially be the result of artificial lighting conditions.

Methods Melatonin levels were determined in eight medical ICU patients on mechanical ventilation, without brain injury or infection. Arterial blood samples were taken on the day of admission at 18:00 (T0D) and 03:00 in the morning (T0M), then at the same time points 48 hours after (TE1, TM1). Blood samples were centrifuged at 3,000 rpm for 8 minutes, and then serum samples were stored at −80°C. Measurements were performed using a US-CEA908ge melatonin ELISA kit. For statistical analysis, a binary (yes/no) variable was created from the pairs for each day, assigning ‘Yes’ if the TE values were greater than TM (melatonin peak reversion). The proportion of reversals and their 95% confidence intervals were estimated using a GEE model for repeated binary data, assuming a binomial distribution and log link, and accounting for subject as a repetition factor. All calculations were done in SAS 9.4.

Results Melatonin levels were not normally distributed and were ranging from 9.2 and 23.7 pg/ml at T0 and 11.3 and 17.9 pg/ml at T1. The median differences of the morning and evening serum melatonin levels were: TM0 – T0D = −2.8 (−3.8 – (−0.2)); TM1 – TE1 = −1.2 (−2.5 – (−0.4)) presented as median (IQR). The proportion of subjects with peak reversals was 92.9% (80.8 to 100.0%).

Conclusion Our preliminary data suggest that circadian rhythm disturbances may occur in critically ill patients within 48 hours after admission, and can be detected by inversion of melatonin peaks. Despite the limitations of this study, it may justify the need for larger observational and randomized trials on the effect of light on melatonin levels and on outcomes in ICU patients.

P550 Trait anxiety mediates stress-related psychopathology after cardiac surgery and ICU stay

L Kok1, M Sepi1, D Veldhuijzen1, S Cornelisse2, A Nierich3, J Van der Maaten4, L Kok1, M Hillegers3
1University Medical Center Utrecht, the Netherlands; 2Leiden University, the Netherlands; 3Amphia Hospital, Breda, the Netherlands; 4Erasmus Medical Center, Rotterdam, the Netherlands

Introduction ICU survivors are at risk for post-traumatic stress disorder (PTSD) and depression. The development of psychopathology depends partially on stable personality factors such as trait anxiety.

The AUC was increased further to 0.781 by including all 14 variables which was higher than each of the individual laboratory parameters.

Conclusion A laboratory-based score was successfully established in ICU patients, revealing an AUC of 0.714 which is comparable with established scores in a similar population. The compilation of the variables to produce a laboratory-based score showed a greater prognostic power than individual variables. Model developers require an AUC of >0.7 to be termed useful; however, in order to be used in a clinical setting the AUC must be at least 0.75. Further research including internal and external validation studies must be performed to optimise the model before clinical implementation.
Among ICU patients a high level of trait anxiety is relatively common and associated with intrusions, a symptom of PTSD. Independently, childhood trauma and stress exposure throughout life have been associated with depression. In cardiac surgery patients admitted to the ICU postoperatively, the effect of trait anxiety on the relationship between cumulative life stress and stress-related psychopathology remains unknown. Therefore we aimed to assess the mediating or moderating role of trait anxiety in this at-risk patient population.

Methods In this multicenter follow-up study of the Dexamethasone for Cardiac Surgery (DECS) trial, validated self-report questionnaires were sent 1.5 to 4 years after cardiac surgery and ICU treatment to assess symptoms of PTSD and depression, in relation to cumulative life stress (that is, childhood trauma, major stressful life events) and trait anxiety as determinants of psychopathology. Data were available for 1,125 out of 1,244 (90.4%) eligible participants. Mediating and moderating analyses were performed with multivariable linear regression to assess the effect of trait anxiety. Subgroup analyses were performed for both sexes.

Results Trait anxiety partially mediates the relationship between cumulative life stress and PTSD (β-value reduction from 0.325 to 0.068; \( P = 0.000 \) to \( P = 0.003 \)) and fully mediates the association between cumulative life stress and depression (β-value reduction from 0.282 to 0.018; \( P = 0.000 \) to \( P = 0.507 \)). Trait anxiety was not a moderating factor between cumulative life stress and psychopathology. Full mediation of trait anxiety was found in female patients (\( n = 247 \)), whereas only partial mediation was seen in male patients (\( n = 878 \)) with regard to PTSD symptoms. As for depression, full mediation was present in both female and male patients.

Conclusion In cardiac ICU patients, trait anxiety mediates the influence of cumulative life stress on the occurrence of PTSD and depression symptoms. Further prospective research is necessary to establish these factors as reliable measures for the early identification of ICU patients at risk for stress-related psychopathology.

P551 Sleep monitoring in ICU patients
S Namba1, K Hayashii, T Hirayama, T Hirayama, Y Namba, M Terado1, P Easton1, Y Ujike2
1Okayama University Hospital, Okayama, Japan; 2University of Calgary, AB, Canada

Introduction Sleep disruption and deprivation is a continuing problem in the ICU. Strategies to improve sleep are confounded by difficulties in monitoring and measuring sleep in the ICU; traditional polysomnography cannot be utilized. Practical, non-intrusive diagnostic techniques of sleep in ICU patients are limited. The aim of the study was to test two new ambulatory sleep diagnostic devices to monitor sleep in the ICU, compare sleep data generated by the different devices, and characterize sleep in the ICU.

Methods The devices were: Watch PAT 200 (Itamar), simple wristwatch style, employing peripheral arterial tone and actigraphy to evaluate sleep and sleep stage by an automatic algorithm (PAT device); and ALICE PDx (Respironics Philips), miniature polysomnographic device utilizing EEG and EMG recordings, requiring post-study sleep technician scoring (PSG device). Nineteen ICU patients provided informed consent (mean age 37 years, two female). Diagnosis of most patients was trauma. Device technical problems terminated one ALICE PDx study and three ICU Watch PAT study; one patient revoked consent. Therefore, 14 patients were recorded successfully in a private room in the ICU, while simultaneously wearing both devices, from 20:00 to 06:00. No patient received sedation. Subjective sleep quality was estimated by the visual analog scale.

Results Both devices calculated total sleep time (TST), but the results were significantly different (\( P < 0.05 \)), with mean TST reported as 443.07 and 270.8 minutes for PAT and PSG devices. WAS correlated tightly with TST calculated by the PSG device (\( r = 0.559 \), \( P < 0.05 \)). Both devices were able to successfully discern different sleep stages, summarized as light sleep, deep sleep, and REM. Measurements of sleep stage were generally in agreement between the two devices; REM sleep time correlated strongly between PAT and PSG devices (\( P < 0.05 \)). Sleep stage distribution was light sleep 62.2% (PAT) and 74.1% (PSG); REM 13.0% (PAT) and 10.7% (PSG); deep sleep 14.5% (PAT) and 7.9% (PSG).

Conclusion Both wristwatch-style PAT and miniature PSG devices successfully recorded sleep in ICU patients. Although the simple PAT device overestimated TST, sleep stage times were generally in agreement, especially REM time which correlated strongly. Both devices can be used to effectively monitor and characterize sleep in the ICU environment.

P552 Hospital anxiety and depression after ICU survival: results of a post-ICU aftercare program
St Elisabeth Hospital Tilburg, the Netherlands

Introduction Although the ICU survival rate has increased in the last decade, the negative effects on mental health and related quality of life become more clear. In the literature the prevalence of anxiety and depressive symptoms post ICU ranges from 10 to 43% [1]. Early recognition and treatment of anxiety and depressive symptoms is important because depression carries a risk for suicide, limited quality of life, and delayed return to work. We studied hospital anxiety and depression (HAD) symptoms after ICU discharge.

Methods Patients who were treated in our ICU from 1 January 2013 until 31 December 2013 for more than 5 days were invited to visit our post-ICU aftercare clinic. Six weeks after discharge they received a letter of invitation together with a health-related questionnaire, the Hospital Anxiety and Depression Scale (HADS) questionnaire [2]. Patients were asked to return the questionnaire prior to their visit. All data were analyzed and if the HADS score indicated a clinically significant anxiety or depression, patients were referred to a psychologist for further analyses and treatment. All patient data were analyzed retrospectively.

Results Seventy-nine patients, 54 men and 43 women, mean age 57 years. Median APACHE II and IV was 18 and 60 respectively. Median ICU and hospitals days were 9 and 20 respectively. Seventy-six percent were mechanically ventilated with a median of 5 days. Median time after ICU discharge to aftercare visit was 165 days. Patients were divided into three categories: 1, no HAD (45.4%); 2, possible HAD (9.3%); and 3, clinically significant HAD (45.4%). Women compared with men showed significantly more HAD symptoms (26.8% vs. 18.6%, \( P < 0.05 \)). Patients with subarachnoid hemorrhage, neurotrauma and multi-trauma patients showed more HAD symptoms. Pain, fatigue, muscle weakness, impairment of daily activity dyspnea, and hoarseness were significantly associated with clinically significant HAD. No association between age and HAD was found. Diagnosis of ICU treatment, length of stay, severity of illness, delirium and use of sedatives were not associated with HAD.

Conclusion Prevalence of clinically significant post-ICU HAD was 45.4%. Female sex and post-ICU physical complaints – pain, fatigue, muscle weakness, impairment in daily activities, hoarseness and dyspnea – were significantly associated with HAD.

P553 Post-traumatic stress disorder after ICU discharge: results of a post-ICU aftercare program
D Ramnarain, I Gninrip, W Schapendonk, A Rutten, G Van der Nat, N Van der Lely
St Elisabeth Hospital Tilburg, the Netherlands

Introduction Patients who survive ICU treatment may experience psychological distress for some time after discharge from the ICU. In the literature the reported prevalence of post-traumatic stress disorder (PTSD) ranges from 5 to 64% [1]. We studied PTSD symptoms in relation to ICU factors, demographic data and physical complaints reported by patients 4 to 6 months after ICU discharge.
was associated significantly with pain, muscle weakness, fatigue, after SAH, reflecting the majority of patients treated in our ICU. PTSD

Conclusion

with PTSD.

of the other demographic data analyzed were significantly associated with PTSD. There was no significant difference in men and women. Sedation, opiates, benzodiazepine, inotropic medication and delirium during ICU treatment were not associated with higher prevalence of PTSD. None of the other demographic data analyzed were significantly associated with PTSD.

Conclusion

Prevalence of PTSD was 43.3% and most seen in patients after subarachnoid hemorrhage (SAH) (28.6%). Pain, muscle weakness, fatigue, impairment in daily activity, dyspnea, and hoarseness reported during the ICU aftercare clinic visit were significantly associated with PTSD. There was no significant difference in men and women. Sedation, opiates, benzodiazepine, inotropic medication and delirium during ICU treatment were not associated with higher prevalence of PTSD. None of the other demographic data analyzed were significantly associated with PTSD.

Introduction

Critical illness today is well recognized as being associated with new or worsening physical impairment, diminished mental health and cognitive dysfunction. We studied the scope of somatic complaints in ICU survivors 4 to 6 months after ICU treatment focusing on somatic complaints is of great importance.

Methods

Patients who were treated in our ICU from 1 January 2013 until 31 December 2013 for more than 5 days were invited to visit our ICU aftercare clinic. Six weeks after discharge a letter of invitation together with a health-related questionnaire, the Hospital Anxiety and Depression Scale questionnaire and Impact of Event Scale (IES-R) questionnaire, was sent to the patient. Patients were asked to return the questionnaires prior to visiting the aftercare clinic. All data were analyzed and if the IES-R score indicated a possible PTSD, patients were referred to a psychologist for further analyses and treatment. All patient data were analyzed retrospectively. The Pearson chi-squared test was used to compare groups and Cramer's V analyses was used to examine strength of the association between groups.

Results

Seventy-nine patients, 54 male and 43 women, with mean age 57 years. Median APACHE II and APACHE IV were 18 and 60 respectively. Median ICU days and hospital days were 9 and 20 respectively. Seventy-six percent of patients were mechanically ventilated with a median of 5 days. Median time of ICU discharge to aftercare visit was 165 days. Delirium occurred in 22 (22.7%) patients during ICU treatment. The prevalence of PTSD was 43.3% and was most seen in patients after subarachnoid hemorrhage (SAH) (28.6%). Pain, muscle weakness, fatigue, impairment in daily activity, dyspnea, and hoarseness reported during the ICU discharge to aftercare visit was significantly associated with PTSD. There was no significant difference in men and women. Sedation, opiates, benzodiazepine, inotropic medication and delirium during ICU treatment were not associated with higher prevalence of PTSD. None of the other demographic data analyzed were significantly associated with PTSD.

Conclusion

Prevalence of PTSD was 43.3% and most seen in patients after SAH, reflecting the majority of patients treated in our ICU. PTSD was associated significantly with pain, muscle weakness, fatigue, dyspnea, hoarseness and impairment of daily activity after a median 165 days post ICU treatment.

Somatic complaints after ICU survival: results of a post-ICU aftercare program

D Ramnarain, W Schapendonk, I Gnmpr, G Van der Nat, A Rutten, N Van der Leij

St Elisabeth Hospital Tilburg, the Netherlands

Introduction

Critical illness today is well recognized as being associated with new or worsening physical impairment, diminished mental health and cognitive dysfunction. We studied the scope of somatic complaints in ICU survivors 4 to 6 months after ICU treatment focusing on somatic complaints is of great importance.

Methods

Patients who were treated in our ICU from 1 January 2013 until 31 December 2013, for 5 or more days, were invited to visit our ICU aftercare clinic. Six weeks after ICU discharge a letter of invitation together with a health-related questionnaire, the Hospital Anxiety and Depression Scale questionnaire and Impact of Event Scale Revised questionnaire were sent. Patients were asked to return the questionnaires prior to visiting our clinic. The main purpose of the post-ICU aftercare was to screen for somatic complaints, mental health and cognitive dysfunction. If necessary, further examination or treatment was advised. All data were retrospectively analyzed.

Results

Ninety-seven patients visited our aftercare program in 2013. Median time after ICU discharge and visit to our aftercare clinic was 165 days. Twenty-five patients died after ICU discharge. Fifty-four patients were excluded because of various reasons; that is, language barrier, psychiatric illness, mental handicap, hospital admittance elsewhere, great distance. Seventy patients (81.4%) had somatic complaints influencing daily performance and quality of life. Fatigue (74.4%), muscle weakness (48.8%), dyspnea (34.9%), impairment of daily activity (81.4%), pain (38.4%) and weight loss (33.3%) were the most frequently reported complaints. Pain was most reported in patients with subarachnoid hemorrhage (27.3%), multitrauma (15.2%) and pneumonia (12.1%). Pain was most localized in the head (15.6%), one or both legs (15.6%), back (10.9%), shoulder (9.3%), hip (9.3%) and thorax (6.3%). Muscle weakness, fatigue, dyspnea, impairment of daily activity, pain and hoarseness were associated significantly with PTSD and HAD. There was no significant difference in somatic complaints between men and women.

Conclusion

Somatic complaints after ICU discharge are frequently reported in our post-ICU aftercare patients, influencing daily performance and quality of life. Patient-centered research and treatment focusing on somatic complaints is of great importance.

Post-traumatic stress disorder prevalence and subtypes among survivors of critical illness

M Patel1, J Jackson2, A Morandi1, T Girard3, C Hughes4, A Kiehl5, J Thompson6, R Chandrasekhar7, E Elly8, P Pandharipande8

1Vanderbilt University, Nashville, TN, USA; 2Ancelle Hospital, Cremona, Italy

Introduction

Among North American survivors of critical illness, we aim to describe the prevalence of post-traumatic stress disorder (PTSD), and its subtypes of intrusion, avoidance, and hyperarousal.

Methods

In this prospective, observational, multicenter cohort study from 2009 to 2010, we screened adults (age ≥18 years) with new-onset respiratory failure, cardiogenic shock, or septic shock, who were admitted to medical and surgical ICUs in four facilities. At 3-month and 12-month follow-ups, high probability of PTSD was defined by 17-symptom PTSD Checklist – Event Specific Version (PCL-S) score ≥50. Also, PCL-S responses were mapped onto DSM-IV criteria for PTSD. To augment PTSD identification, those with a moderate probability of post-ICU PTSD (PCL-S score ≥35) were further confirmed with the Clinician Administered PTSD Scale (CAPS) structured interview. Moderate or greater symptoms for each PTSD subtype of intrusion, avoidance, and hyperarousal were categorized.

Results

Of the 180 eligible participants at 3 months, PTSD was identified in 10 (6%) using PCL-S scores and 15 (8%) using DSM-IV mapping of the PCL-S. Of the 160 eligible participants at 12 months, PTSD was identified in two (1%) using PCL-S scores and 10 (6%) using DSM-IV mapping of the PCL-S. Of those eligible for CAPS assessments, at 3 months only 13 of 24 (54%) interviews were completed resulting in three extra PTSD diagnoses, and at 12 months only six of 22 (27%) interviews were completed resulting in two extra PTSD diagnoses. At 3 and 12 months, the intrusion subtype was present in 25 (14%) and in 25 (16%), the avoidance subtype was present in 78 (43%) and 60 (38%), and the hyperarousal subtype was present in 82 (46%) and 71 (44%).

Conclusion

Irrespective of definition using PCL-S or DSM-IV mapping, PTSD was identified in no more than one in 10 survivors of critical illness at either 3 or 12 months post ICU, which is still nearly double the US population past-year PTSD prevalence. In ICU survivors with moderate probability PTSD by PCL-S, the CAPS gold-standard interview is challenging to complete and adds only a small number of diagnoses. However, two in five ICU survivors will develop PTSD subtypes of avoidance or hyperarousal, which both occur twice as frequently as the intrusion subtype. Targeting predominant PTSD subtypes may help optimize treatment strategies for the ICU survivor, such as prolonged exposure and eye movement desensitization and reprocessing for those with the avoidance subtype, and pharmacologic antidepressants targeting the sympathetic nervous system to produce anxiolysis for those with the hyperarousal subtype.

P556

Nonpharmacological interventions to reduce short-term or long-term psychological stress in ICU patients: a systematic review

D Warde1, Z Mooni1, S Windgassen2, J Weinman3

1University College Hospital, London, UK; 2Kings College London, UK

Introduction

A systematic review was performed of studies of nonpharmacological interventions aiming to reduce short-term or long-term stress in intensive care patients, as little is known about the...
efficacy of such interventions. Previous work has shown that intensive care patients undergo many stressful experiences, which can affect their long-term psychological well-being. Studies have demonstrated a high prevalence of depression, anxiety, and post-traumatic stress disorder after intensive care admissions.

Methods A systematic review was carried out according to the Prisma statement. A search was conducted of Medline, Embase and Psychinfo databases. Inclusion criteria included studies of populations of adult patients in mixed or general ICUs. No study designs were excluded, but studies that focused on specific disease states were excluded. Included studies were assessed for risk of bias, using a quality checklist.

Results A total of 1,743 papers were retrieved, of which 18 studies were eligible for inclusion in the review. Studies had a combined population of 1,970 patients admitted to 38 ICUs from Europe, Asia and North America. Eleven studies were randomized controlled trials (RCTs). Interventions were classified as four groups – music; therapeutic touch; diary and psychotherapeutic interventions. Ten studies found that music interventions were effective in the short term; however, follow-up results were limited and some studies were of low quality. There was moderate quality evidence from three studies for the effectiveness of diary interventions, with medium-term follow-up results. There was mixed-quality evidence for therapeutic touch interventions in the short term from three studies. The two psychotherapeutic interventions studied were of moderate quality, and one showed promising results at 12-month follow-up.

Conclusion The evidence for the efficacy of nonpharmacological interventions to reduce short-term or long-term stress in intensive care patients was of low to moderate quality. Studies included mainly short-term and medium-term follow-up. This highlights the need for large-scale, better-quality RCTs with longer-term outcome measurement. However, the results indicate that nonpharmacological, including psychological, approaches are likely to be beneficial for reducing short-term or long-term stress in intensive care patients.

P557 Utilisation of existing community rehabilitation services by critical care survivors
CR Soulsby, J McPeake, C Ashcroft, J Kinsella, M Shaw, T Quasim
University of Glasgow, UK

Introduction Patients recovering from critical illness suffer many physical and psychological problems during their recovery, including muscle weakness, fatigue, signs and symptoms of PTSD, anxiety and depression [1]. At present, specialist intensive care follow-up and rehabilitation is inconsistent and in many geographical areas is nonexistent. As a result, many survivors of critical illness will require using existing community rehabilitation services [2]. The aim of this present service evaluation was to understand the utilisation of community rehabilitation services by critical care survivors.

Methods A database of acute referrals to community rehabilitation services was retrospectively analysed from 1 May 2014 to 31 October 2014. Age, referring specialty and reason for referral for rehabilitation were documented. This database was cross-checked with the critical care database in Glasgow Royal Infirmary to identify which individuals had been admitted to critical care during their admission.

Results Over this 6-month period 769 patients were referred from their parent specialty for community rehabilitation in North East Glasgow. Thirty-three of the 769 patients (4.3%) referred had a critical care stay during their admission. Of these, eight patients were referred for rehabilitation by orthopaedics, eight by medicine for the older patients, 11 from acute medicine and the remaining six from other specialties. Six of the 769 patients who had a critical care admission were of working age (<1%). Two individuals were admitted to critical care following trauma whilst four had complex social needs prior to their critical care admission. This included an individual with a high body mass index. None of the individuals of working age were referred as a consequence of their critical care stay.

Conclusion This service evaluation demonstrates that very few critical care survivors are referred to community rehabilitation services, particularly those of working age. More work is required to understand optimal rehabilitation pathways in this patient group.

P558 Physiotherapy in the ICU: an evidence-based, expert-driven, practical statement
J Sommers1, R Engelbert1, D Detting1, R Gosselink1, P Sproon2, J Horn1, F Nollet1, M Van der Schaaf1
1Academical Medical Center, Amsterdam, the Netherlands; 2School of Health, Amsterdam, the Netherlands; 3KU Leuven, Belgium; 4Gelre Hospital, Apeldoorn, the Netherlands

Introduction Evidence-based, expert-driven, practical statements improve quality and effectiveness of the diagnostic and therapeutic process of patient care. Although the effectiveness of physiotherapy treatment strategies in ICU patients has been described, statements or guidelines of physiotherapy for ICU patients are not available [1]. Guidelines on safety management and on the diagnostic and therapeutic process may support and guide clinical decision-making leading towards evidence-based tailored care. The aim of this study was to develop an evidence-based statement for the physiotherapy treatment of ICU patients with recommendations for effective and safe diagnostic assessment and intervention strategies.

Methods For the development of the evidence statement, we used the EBRO method, as recommended by the Dutch Evidence Based Guideline Development Platform [2]. This method consists of the identification of clinically relevant research questions, followed by a systematic literature search, quality assessment, and summary of the evidence eventually leading to establishing of concept and final recommendations based on feedback from experts. The final recommendations were prepared according to this methodical approach and summarized in figures, flowcharts and appendices.

Results Three expert-based relevant clinical questions were formulated within the physiotherapy clinical reasoning process and were classified according to the International Classification of Functioning, Disability and Health. In a systematic literature search, 129 studies were identified and assessed for methodological quality and classified according to the level of evidence. The final Evidence Statement consisted of recommendations for physiotherapy in ICU patients including safety criteria, a core set of instruments to assess impairments and activity restrictions and effective interventions.

Conclusion The Evidence Statement for physiotherapeutic diagnostics and intervention in ICU patients will contribute to the quality of clinical practice by supporting the clinical decision-making process.

P559 Early mobilization according to diagnosis in a Brazilian coronary ICU
GS Zavanelli1, SA Padulla1, MR Franconci1, RZ Finto1, LL Faccoli1, DN Barbosa1, DT Neves1, CE Bossa1
1Universidade Estadual Paulista – UNESP, Presidente Prudente, Brazil; 2Instituto do Coração de Presidente Prudente, Brazil

Introduction Early mobilization has been advocated to improve muscle function and, consequently, the patient quality of life after discharge. Nevertheless, few studies have explored it in a coronary ICU (CICU). The aims of the present study were to describe the use of an early mobilization protocol in a CICU and to investigate whether different groups of diagnoses respond similarly to this protocol.

Methods This is a retrospective observational study conducted in a medium-sized hospital located in the city of Presidente Prudente,
Brazil. The early mobilization protocol consists of five phases: 1 – passive exercises for the unconscious patient; 2 – active exercises associated with respiratory exercises (patient lying on the bed); 3 – phase 2 exercises with the patient sitting on the bed; 4 – phase 2 exercises with the patient sitting on a chair or in a standing position; 5 – phase 4 exercises plus walking. All hospital records from patients, between September 2013 and August 2014, were included in this study. Data extracted from hospital records were: age, gender, diagnosis (arrhythmia, coronaryopathies, congestive heart failure and other pathologies), length of stay, number of discharge and number in each phase of the early mobilization protocol. Pearson chi-square test was used to compare the number of mobilizations (phase 4 and 5) per group of diagnoses. Odds ratios were calculated for those comparisons found to be statistically significant (P < 0.05).

**Results**

A total of 697 hospitals records were analyzed. Patients had on average (SD) 67.8 (13.1) years and the majority of them were males (57%). Our results revealed that 65% of patients in the CICU received phase 4 and 43% of patients in the CICU received phase 5 of the early mobilization protocol. No differences in the proportion of patients receiving phase 4 or 5 were found among arrhythmia, coronaryopathies and congestive heart failure groups. The only difference found was between congestive heart failure group and other cardiovascular pathologies (P < 0.001). The congestive heart failure group was mobilized 5.6 times (95% CI: 2.7 to 11.5) and 3.2 times (95% CI: 1.7 to 5.7) more than the other cardiovascular pathologies group in phase 4 and 5, respectively.

**Conclusion**

A considerable proportion of patients was mobilized without any serious complications in the CICU. Our findings suggest that patients diagnosed with congestive heart failure can be equally mobilized in an ICU.

**Need for therapeutic interventions as a predictor of mortality in intensive care**

I Efendijev1, R Raj1, S Hoppu2, MB Skrifvars1, M Reinkainen1

1HUS, Helsinki, Finland; 2TAYS, Tampere, Finland; 3PKKS, Joensuu, Finland

**Introduction**

Various therapeutic interventions needed in critical care may reflect a high risk of death. We evaluated associations between commonly used interventions and hospital mortality in Finnish ICU patients.

**Methods**

We retrieved data on adult patients treated in Finnish ICUs between 2003 and 2013 from the Finnish Intensive Care Consortium database. We used the Therapeutic Intervention Scoring System (TISS) to categorizing ICU interventions and the Simplified Acute Physiology Score (SAPS II) for quantifying severity of illness. We excluded readmissions, patients with missing outcome, SAPS II and TISS data. We also excluded very common interventions (arterial line, bolus intravenous medication), very rare ones (prevalence <1%), and interventions only applicable in specific populations (intracranial pressure monitoring, intra-aortic balloon assist). We grouped several TISS categories when applicable. We performed a backward stepwise binary logistic regression analysis with TISS items to assess the impact of each intervention on hospital mortality (expressed as odds ratio (OR) with 95% confidence intervals (CIs)). Age, admission type, and SAPS score (minus age and admission type scores) were adjusted for in the multivariate analysis.

**Results**

We identified 161,134 patients eligible for analysis. The multivariate analysis showed that the highest risk for hospital mortality in all patients was associated with cardiac arrest and/or countershock, OR 2.38 (95% CI = 2.43 to 2.73), SAPS II emergency admission, OR 2.52 (95% CI = 2.32 to 2.74), vasoactive drug infusion (>1 drug), OR 1.66 (95% CI = 1.59 to 1.73) and blood transfusion (a combined TISS item), OR 1.53 (95% CI = 1.44 to 1.63). TISS items associated with the lowest risk of mortality in general population were: active anticoagulation, OR 0.51 (95% CI = 0.49 to 0.53), induced hypothermia, OR 0.68 (95% CI = 0.62 to 0.74) and measurement of cardiac output by any method, OR 0.87 (95% CI = 0.83 to 0.91). All aforementioned associations were statistically significant (P < 0.001). There was no notable association with mortality for pulmonary artery catheter, platelet transfusion and vasoactive drug infusion (one drug) (P > 0.05).

**Conclusion**

In this large retrospective multicenter study, the TISS item associated with the highest risk of death was cardiac arrest and/or countershock. Unexpectedly, the independent effect of emergency admission was of comparable magnitude in terms of impact on hospital mortality. Of these, in-ICU cardiac arrest might be amenable to preventive measures and should be studied further.

**Payment options: do they affect outcome in the critically ill**

A Kar, A Datta

Medica Superspeciality Hospital, Kolkata, India

**Introduction**

Increasing cost is an important issue in critical care medicine. We tried to analyze in a level 3 care ICU in Kolkata of a tertiary care hospital whether the different payment options (self-paying vs. insurance/corporate paying) do affect the outcome in the critically ill.

**Methods**

Our prospective study included 1,520 patients admitted consecutively to a level 3 care ICU for a period of 20 months. Readmitted patients during the same period were excluded. Payment method was documented for all and divided into two groups as self-paying and insurance/corporate paying. Outcome assessment was done using the APACHE IV model for all cases. Demographic data, number of observed deaths, predicted mortality rate (PMR), standardized mortality ratio (SMR), average length of stay (ALOS), predicted length of stay, and number of discharge against medical advice (DAMA) were documented for each group. Statistical analysis was carried out using unpaired Student t test and P < 0.05 was considered significant.

**Results**

Of 1,520 patients, 995 (65.46%) cases were self-paying while 525 (34.54%) cases were insurance/corporate paying. In the self-paying group, mean age was 59.65 years ± 17.26 SD (median 62), APACHE IV score mean was 62 SD ± 33.61 SD (median 57), average LOS 4.67 days ± 4.29 SD (median 3), PMR was 22.71, 226 observed deaths, 85 cases of DAMA, and SMR was 1.00 (CI = 0.87 to 1.14). In the insurance/corporate-paying group, mean age was 61.75 years ± 17.19 SD (median 65), APACHE IV score mean was 58.53 ± 32.94 SD (median 54), average LOS was 5.64 days ± 5.61 SD (median 4), PMR was 21.26, 113 observed deaths, six cases of DAMA, and SMR was 1.01 (CI = 0.83 to 1.21). In the two compared groups, predicted mortality and SMR were not statistically significant (P = 0.2808); however, ALOS in the insurance/corporate paying group was significantly higher than the self-paying group (P = 0.0002), mean age of the insurance/corporate paying group was significantly higher than the self-paying group (P = 0.02), and incidence of DAMA is significantly higher in the self-paying group (P = 0.04) as compared with insurance/corporate paying group (1.14%). Root-cause analysis showed DAMA cases are mostly financial (>95%).

**Conclusion**

Statistically significant differences in ALOS and DAMA in the two groups are probably due to cost of healthcare not affordable to all.

**P562**

**Source of ICU admission: does it really matter?**

A Datta, A Kar, A Ahmed

Medica Superspeciality Hospital, Kolkata, India

**Introduction**

Source of admission to the ICU is of importance. We tried to identify the different sources of ICU admission to a level 3 ICU of a tertiary care hospital in Kolkata and analyze whether the overall patient outcome is affected by the different sources of admission.

**Methods**

Our prospective study included 2,056 patients admitted to a level 3 care ICU over a period of 2 years. Numbers of readmissions were not considered. ICU outcome was analyzed using the APACHE IV model and source of admission to the ICU was documented as either from emergency (ER), from the floor or from other hospital. Analysis was carried out between different groups based on admission using unpaired Student t test and P < 0.05 was considered significant. Number of ventilations and the mortality rate in each group were also documented.
Results Of 2,056 admissions, 1,223 cases (59.48%) were from ER, 809 cases (39.35%) were from floor and 24 cases (1.16%) were from other hospitals. In the ER group, mean APACHE IV was 55.03 ± 31.49 SD (median 50), PMR 16.26, observed deaths 198, ALOS 4.78 days ± 4.83 SD (median 3), SMR 0.995 (CI = 0.86 to 1.14), mean age 60.52 years ± 17.63 SD (median 63), 323 ventilations. In the floor group, mean APACHE IV was 65.17 ± 34.40 SD (median 60), PMR 27.03, observed deaths 234, ALOS 5.23 days ± 5.22 SD (median 3), SMR 1.07 (CI = 0.94 to 1.21), mean age 61.38 years ± 15.72 SD (median 64), 302 ventilations. In the other hospitals, mean APACHE IV was 55.29 ± 29.82 SD (median 50), PMR 18.0, observed deaths 2, ALOS 6 days ± 5.85 SD (median 3), SMR 0.46 (CI: 0.23 to 0.88), mean age 56.08 years ± 17.79 SD (median 56.5), six ventilations. During analysis, the other hospital group was omitted because of inadequate sample size. There was statistically significant differences in APACHE IV (floor > ER, \(P < 0.0001\)), PMR (floor > ER, \(P < 0.0001\)), ALOS (floor > ER, \(P = 0.04\)) noted between the floor and ER groups. Number of ventilations (37.33% vs. 26.4%), SMR (1.07 vs. 0.995), and mortality rate (28.92% vs. 16.19%) were also significantly higher for patients admitted from the floor. No significant statistical difference was observed in age between two groups (\(P = 0.26\)).

Conclusion The severity of illness index in patients admitted to the ICU from floors is significantly higher than emergency admissions. Overall APACHE IV and mortality rate was higher in the floor compared to the ICU from the floor. It is worse based on mortality rate, SMR, and ALOS when compared with the emergency group.

P563
Readmission to the ICU: is it a big concern? An analysis
A Ahmed, A Datta, A Kar
Medica Superspeciality Hospital, Kolkata, India

Introduction Readmission to the ICU is an important quality indicator of ICU care. We conducted a prospective study in a level 3 care ICU in Kolkata of a tertiary care hospital to analyze whether there are overall outcome differences when comparing the readmission group with the entire group.

Methods Our prospective study included 2,140 patients admitted to a level 3 care ICU over a period of 1 year. The number of readmissions (\(n = 85\)) during the same period was also documented. Readmission was defined as all patients who were transferred back to the ICU prior to hospital death/discharge during the above period. ICU outcome was calculated using the predictive APACHE IV model. Payment methods were documented as either self-paying or corporate/insurance paying. A comparison analysis between the entire group with the readmission group was done using unpaired Student \(t\) test and \(P < 0.05\) was considered statistically significant.

Results In the entire group (\(n = 2,140\), mean APACHE IV was 50.34 ± 31.54 SD (median 42), PMR 15.49, observed deaths 327, ALOS 4.05 days ± 4.55 SD (median 3), SMR 0.99 (CI = 0.88 to 1.1), mean age 60.55 years ± 15.68 SD (median 63), 490 ventilations, 72.71% of patients were self-paying while 27.29% of patients were corporate/insurance paying. In the readmission group (\(n = 85\)), mean APACHE IV was 77.16 ± 33.72 SD (median 73), PMR 38.89, observed deaths 42, ALOS 5.23 days ± 4.18 SD (median 4), SMR 1.27 (CI = 0.95 to 1.67), mean age 64.79 years ± 14.40 SD (median 67), 43 ventilations, 75.3% of patients were self-paying while 24.7% of patients were corporate/insurance paying. During comparison between the two groups there were statistically significant differences, with the readmission group having significantly higher APACHE IV (\(P < 0.0001\)), PMR (\(P < 0.0001\)), ALOS (\(P = 0.002\)), age (\(P = 0.005\)), and SMR (1.27 vs. 0.99) compared with the entire group. Percentage of patients requiring ventilation (50.59% vs. 22.90%) and mortality rate (49.11% vs. 15.28%) were also significantly higher in the readmission group. Readmission was significantly higher in the self-paying group. Root-cause analysis showed most readmissions were due to non-paying conditions (desaturation, hypotension, sepsis, arrhythmias); however, it was also associated with cases where transfer policy from the ICU was not followed by stakeholders and financial issues were a cause of early transfer.

Conclusion Readmission to the ICU was associated with worse outcome in our study group. Lack of adherence to transfer policy by concerned stakeholders was a concern as well as increasing cost of healthcare.

P564
Association between out-of-hours discharge and mortality in adult patients leaving critical care
S Edie, K Burt, J Paddle
Royal Cornwall Hospital, Truro, UK

Introduction Out-of-hours (OOH) discharge from critical care is associated with a significantly increased mortality rate in Australia [1]. However, the impact of OOH discharges from critical care are considered a core standard [2]. We sought to assess the impact of OOH discharge from critical care on mortality in a large general ICU, where operational pressures appear to have led to a high rate of OOH discharges.

Methods Retrospective data for all patients admitted to our ICU from April 2007 to September 2014 were recorded, using routinely collected data from our databases. Adult patients (>15 years) discharged from their first ICU admission during each hospital stay (episode) were included. Patients that died on the unit and those discharged for palliative care were excluded. Patients transferred to other centres were no longer subject to discharge within our control and were therefore also excluded. Patients discharged directly home from ICU were excluded. We defined OOH discharges as those occurring between 22:00 and 06:59, a standard definition in UK practice. Mortality status at the time of hospital discharge for each episode was used. We also recorded the readmission rate to ICU. The relative risk (RR) for OOH mortality and readmission was calculated. Statistical significance was accepted at \(P < 0.05\).

Results Of 4,476 index cases, 714 died on the unit and 80 were discharged for palliative care. A total of 490 patients were excluded for transfer to other centres and discharge directly home. Data were missing for three patients, which left 3,189 records for analysis. In total, 2,711 patients were discharged during daytime hours, of which 145 (5.33%) died. A total of 478 patients were discharged at night, 40 died (8.37%). The RR for OOH mortality was 1.56 (95% CI = 1.12 to 2.19, \(P = 0.0091\)). Readmission rate was 5.2% by day, 6.1% at night. The RR for readmission was 1.17 (95% CI = 0.79 to 1.72, \(P = 0.436\)).

Conclusion Our data demonstrate an association between critical care discharge time and mortality, to a statistically significant level. Due to the retrospective observational nature of the study, causation cannot be assumed; however, a number of factors may contribute to the increased risk of harm to patients discharged from the ICU at night. Further work will focus on national OOH mortality trends, thereby gaining an insight into whether bed occupancy demands impact on the necessity for nighttime discharges.

Recovery of health-related quality of life in ICU patients: a 5-year prospective cohort study
J Huthuis1, HF Van Stefl 2, AJ Schrijvers1, JH Rommes1, PE Spronk1
1 Gele Hospitals, Apeldoorn, the Netherlands; 2University Medical Center, Utrecht, the Netherlands

Introduction Severe critical illness requiring treatment in the ICU may have a serious impact on patients and their families. However, optimal follow-up periods are not defined and data on health-related quality of life (HRQOL) before ICU admission as well as those beyond 2-year follow-up are limited. The aim of our study was to assess the impact of ICU stay up to 5 years after ICU discharge.

Methods We performed a long-term prospective cohort study in patients admitted >48 hours to a medical–surgical ICU. The Short-Form 36 was used to evaluate HRQOL before admission (by proxy within 48 hours after admission of the patient), at ICU discharge and at 1, 2 and 5 years following ICU discharge (all by patients). Changes in HRQOL were assessed using linear mixed modeling.

Results We included a total of 749 patients (from 2000 to 2007). At 5 years after ICU discharge, 234 patients could be evaluated. After...
correction for natural decline in HRQOL, the mean scores of four dimensions – physical functioning (P < 0.001), physical role (P < 0.001), general health (P < 0.001) and social functioning (P = 0.003) – were still significantly lower 5 years after ICU discharge compared with their preadmission levels, although effect sizes were small (<0.5).

Conclusion Five years after ICU discharge, survivors still perceived a significantly lower HRQOL than their preadmission HRQOL (by proxies), and that of an age-matched general population. Importantly, however, after correction for natural decline, the effect sizes were small suggesting that patients regain their age-specific HRQOL 5 years after their ICU stay.

Determination of brain death for adult patients with ECMO

1Ceylan R, Iscimen E, Czmeci N, Kelebek Gürpinar F, Kahveci Uludag University Faculty of Medicine, Bursa, Turkey

Introduction ECMO support in ARDS is an emerging strategy when conventional treatment modalities fail. ECMO has advantages on oxygenation and circulation but also it has some unfavorable effects. The most serious complication is brain death due to cerebrovascular hemorrhage. An apnea test is the most important component in confirming brain death. For patients supported by ECMO, apnea testing remains challenging. Brain-death diagnosis is often made without an apnea test.

Methods We present two cases who receive V-V ECMO support after progression to ARDS. After initiation of ECMO we used sedation to prevent movement and improve adaptation to mechanical ventilation. Also we used anticoagulation with heparin to prevent thromboembolic events and ECMO circuit occlusion. On daily follow-up we noticed that patients had lost their pupil reactions to light. Their sedation was ceased and a computed brain tomography was performed. Both patients had intracerebral hemorrhage. We decided to determine brain death with apnea tests. We increased ECMO blood flow and fi O2 and then decreased sweep gas flow and disconnected the patient from mechanical ventilation respectively. In one patient we did not see any spontaneous breathing efforts after carbon dioxide retention. We concluded that the apnea test was successful and confirmed brain death. On the other hand, we confirmed the brain death of the other patient with cerebral angiography due to the occurrence of hypoxia and hypotension during apnea testing.

Results We experienced some challenges while determining brain death in patients under ECMO support for ARDS. It is challenging to conduct the apnea testing during ECMO support. Auxiliary tests are required for patients who cannot tolerate the changes needed to conduct the apnea test. With increasing use of ECMO therapies, clinicians may come face to face with more complicated life-ending decisions.

Conclusion Current guidelines do not include brain death criteria using supportive therapies such as ECMO and therefore should be updated.

Making it safe to speak up about futile care: a multiperspective survey on leadership, psychological safety and perceived futile care in the ICU

D Schwarzkopf, J Felle1, CS Hartog1, F Bloos1
1Jena University Hospital, Jena, Germany; 2Helmut Schmidt University, Hamburg, Germany

Introduction Psychological safety (PS), for example safety of speaking up, fosters team learning and prevents treatment errors on the ICU [1]. Since speaking up might also prevent excessive and inappropriate (futile) care for patients, we hypothesized that teams with higher PS report less perceived futile care (PFC). We also expected that attending physicians’ inclusive leadership (IL), which invites nurses’ and residents’ participation [2], would decrease PFC and that PS mediates this relationship.

Methods The hypotheses were tested in a cross-sectional, multicenter paper-and-pencil survey addressing medical staff on participating ICUs. A total of 22 ICUs and four intermediate care units were included in the sample and 73 attendings, 147 residents and 659 nurses participated in the study (52% participation). Psychometric properties were tested by confirmatory factor analysis (CFA), Cronbach’s α and intraclass correlations (ICC). A series of hierarchical linear models (HLM) were conducted to test the study hypotheses separately among nurses/residents and attendings. IL and PS were entered as unit-level predictors (mean values per unit). Covariates were demographics, working hours per week, workload and unit size (number of staff).

Mediation effects were tested.

Results The CFA showed a good fit indicating factorial validity (CFI: 0.97), reliabilities were from α 0.79 to 0.93 and ICCs were significant (P < 0.20, P < 0.001). HLM revealed that unit-level IL of nurses and residents was positively related to PS (b = 0.34, P < 0.001). Being a resident and working in a smaller unit also predicted PS. As expected, unit-level PS was negatively related to individual PFC (b = −0.38, P = 0.025). Further predictors of higher PFC were being a nurse, having more than 5 years of job experience and higher workload. PS mediated the relationship between unit-level IL and individual PFC (indirect effect: −0.13, P < 0.001). Additional analyses revealed that attending’s PFC was negatively related to their perception of residents PS (b = −0.44, P = 0.019).

Conclusion A sense of PS in an ICU team might reduce futile care by increasing the safety of speaking-up behavior of nurses and residents. PS can be enhanced by attending physicians who practice inclusive leadership behavior to foster autonomy and participation of residents and nurses.

End-of-life decisions: how do patients die in the ICU?

S Barbosa, P Cavaleiro, J Guedes, S Castro, C Granja
Unidade de Faro – Centro Hospitalar do Algarve, Faro, Portugal

Introduction One of the main goals of intensive care medicine is to reduce the mortality of critically ill patients. However, it is essential to recognize end-of-life care as an integral component of critical care. Besides survival, the success of intensive care should also include the quality of lives preserved and the quality of dying. The objective of this study was to evaluate the incidence and type of end-of-life decisions (ELD) in critical patients that died in an ICU.

Methods Analysis of all patients included in an ICU running database and who died from 1 November 2013 to 31 October 2014. The following variables were evaluated: age, gender, reason for admission, SAPS II, length of ICU stay and type of ELD. To classify ELD, four concepts were defined: ‘Comfort care’, a change from curative therapy to comfort care therapy; ‘Limited therapy’, maintenance of curative therapy but without escalating it (for example, no renal substitution); ‘Decision not to resuscitate’, not to perform advanced life support if cardiac arrest occurs; and ‘Without previous end-of-life decisions’, when there was no prior decision regarding the ELD.

Results A total of 507 patients were admitted to the ICU and 132 died (26%). Reasons for admission in those who died were septic shock (47%), post cardiac arrest (13%), cardiogenic shock (8%), and nontraumatic brain bleeding (8%). Fifty-three patients (40%) died after a ‘Comfort care’ decision, 28 patients (21%) after ‘Decision not to resuscitate’ and 14 (11%) after a ‘Limited therapy’ decision. Thirty-seven patients died ‘Without previous end-of-life decisions’. However, specifically in this group, when looking for individual records, 32 patients died (86%) in the first 48 hours after the admission and four (11%) had evidence of brain death and were organ donors, which leaves one patient (3%) in whom there was no ELD.

Conclusion In this study, ‘Comfort care’ was the main ELD, which is in line with the concept that ELD are essential to ensure that care provided is
consistent with quality of life and death. The apparent large proportion of patients 'Without previous end-of-life decisions' was due to patients who died in the first 48 hours after ICU admission corresponding to conditions refractory to treatment. Additionally, this study also draws our attention to better plan ICU admissions and hospital outreach in order to reduce early ICU mortality.

Do intensivists prognosticate patients differently from themselves or their loved ones?

S Gupta, C Green, R Trinoiopathi, J Botha

Peninsula Health, Frankston, Australia

**Introduction** There is a paucity of data about whether our treatment philosophy is different for our patients as compared with what we would have wanted for ourselves, or while acting as surrogate decision-makers for our loved ones.

**Methods** An anonymous survey was sent to all the members of Australia and New Zealand Intensive Care Society and the College of Intensive Care Medicine (CICM). The first section comprised a hypothetical case scenario spanning over 6 weeks of ICU stay for a patient. At four different stages of the ICU stay, responders were requested to answer multiple-choice questions regarding the philosophy of treatment, based on their perceived prognosis of the patient at that particular time. The following two sections contained the same set of questions with the hypothetical scenario of responders acting as surrogate decision-makers for the patient and that of responders being patients themselves, in the same situation. The responses were compared amongst three sections at each stage using the chi-square test.

**Results** A total of 115 responses were received from the fellows of CICM. The results are presented in Tables 1 and 2.

**Table 1 (abstract P569). Respondents advocating withdrawal for the patient**

<table>
<thead>
<tr>
<th></th>
<th>Withdrawal self (%)</th>
<th>Withdrawal family (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Day 3</td>
<td>71</td>
<td>67</td>
</tr>
<tr>
<td>Day 7</td>
<td>83</td>
<td>76</td>
</tr>
<tr>
<td>Day 28</td>
<td>96</td>
<td>88</td>
</tr>
<tr>
<td>Day 42</td>
<td>98</td>
<td>97</td>
</tr>
</tbody>
</table>

**Conclusion** Of the ICU physicians who would withdraw care for their patient, the majority would also want the same for themselves. The disparity between decision to continue to treat the patients versus treating self or family increased with increasing length of stay.

Evaluation of screening criteria for palliative care in an emergency department ICU

S Ribeiro, R Carvalho, P Ayres, D Barros, D Roger

Hospital das Clinicas School of Medicine, University of Sao Paulo, Brazil

**Introduction** A high percentage of patients admitted to ICUs fulfill one or more criteria for palliative care settings. There are currently few comprehensive studies in critical care settings that have set out to examine the association of palliative care screening criteria with adverse patient outcomes.

**Methods** We performed an observational unicentric study on a 12-bed, medical emergency department intensive care unit (EDICU). A three-item palliative care screen was developed from consensus reports. A senior critical care physician screened patients upon admission using these questions during a 10-week period. The questions were: does this patient suffer from a life-limiting disease (end-stage lung, liver, heart or kidney disease, severe neurological disability, extreme frailty, locally advanced or metastatic cancer, advanced stage AIDS). If the answer to the first question is yes, we proceed to the next one: do you believe this patient will survive to hospital discharge? Answers to those questions were recorded, SAPS III was calculated and all patients were followed until death, discharge or transfer to another center. Differences in mortality and SAPS III score between groups were examined using a Student’s t test. Proportions were compared using chi-square test.

**Results** During the period, 191 patients were admitted to the EDICU, from which 151 had complete data and follow-up. A total of 63 patients (41.7%) suffered from a life-limiting disease and were evaluated as having a high probability of death in 1 year. This group was further divided between 35 patients who in the moment of initial screening were expected to die in this hospital admission and 28 patients who were believed to survive to discharge. Comparison between these two groups showed patients believed to die at this hospital admission had higher SAPS III scores (66.9 vs. 59, P = 0.010) and hospital mortality (48.6% vs. 10.7%, P = 0.001).

**Conclusion** A high percentage of patients admitted to our EDICU have life-limiting disease and might benefit from palliative care. These patients can be identified using simple screening questions at admission and positive answers to those questions can be associated with worse outcomes.

Parents’ return to the hospital after the death of their children: importance of palliative care after death

G Halal, PL Lago, J Piva, M Halal

Hospital de Clinicas de Porto Alegre, Brazil

**Introduction** To analyze the perception of parents regarding their return to the hospital where their children died to participate in a conversation with doctors and to analyze the feelings of parents about their participation in a study evaluating the care provided in the moments leading up to the death of children.

**Methods** A descriptive exploratory qualitative study. The study sites were the pediatric ICUs of the Hospital São Lucas and Hospital de Clinicas de Porto Alegre. Fifteen parents of children who died in the PICUs studied participated in the study. Data collection occurred in 2010 and was conducted through semistructured interviews. Data were analyzed using thematic content analysis. The research was approved by the research ethics committees of both hospitals.

**Results** The ability to return to the hospital and talk to medical assistants was considered by parents as a positive and enlightening opportunity. Parents who participated in the study understood this moment as an opportunity to be heard and demonstrated the intention to contribute with their experiences in order to improve care in the hospitals studied.

**Conclusion** We conclude that there is a need to implement measures to provide palliative care to parents after the death of their children. It is necessary to consider the possibility of providing families with follow-up meetings with the multidisciplinary team after the death of children.

How readable are our Patient Information Sheets?
L Strachan, M Booth
Glasgow Royal Infirmary, Glasgow, UK

Introduction
We often need to obtain consent for clinical studies in the ICU. Participant Information Sheets (PIS) can be difficult to understand. A recent French publication [1] supports our hypothesis that PIS have poor readability scores.

Methods
Protocols submitted for ethics approval between 2008 and 2009 were obtained with permission from the Scotland A Ethics Research Committee. Ethical approval was not required for this observational study. All header, footers, diagrams and tables were removed. Readability scoring was performed using the Flesch Reading Ease and Flesch–Kincaid (FK) grades. Statistical analysis using Excel and MiniTab was then performed. The readability of these documents was compared with everyday documents – newspaper articles, politicians’ speeches [2] and standard contract agreements.

Results
A total of 104 protocols containing 209 PIS were reviewed. Of these, 99 (47%) were written for patients, 56 (27%) for GPs, 26 (12%) for relatives, 17 (8%) for carers, five (2%) for legal representatives and six (3%) were summary sheets only. Sixty-seven (64%) of these protocols were submitted by academic institutions (for example, university or health boards) and 37 (36%) by pharmaceutical companies. Results are expressed as the median and 25th and 75th percentiles. The word count and number of pages were higher for those PIS submitted by pharmaceutical companies compared with academic institutions: 1,561 (77; 5,167) versus 1,177 (626.5; 1,559.8) with P < 0.05 and 4 (2; 10) versus 3 (2; 4) with P < 0.05 respectively. The Flesch Reading Ease (63 (56; 69) vs. 60 (52.6; 65.4)) and FK grades (3 (5.4; 7.2) vs. 6.8 (6.7; 7.6)) were similar for both groups. Further subanalysis demonstrated that PIS designed for GPs had a lower word count, lower Flesch and higher FK grade compared with those for patients – the difference in Flesch Reading Ease and FK grade were compared using a Mann–Whitney test and were statistically significant.

Conclusion
The FK grade is equivalent to US school grade level. The US government advises all policies produced should have a FK grade of <9. Our study suggests that protocols submitted to the ethics committee are easy to read, comparing favourably with broadsheet journalism and standard contract, for example loan contract. However, the average reading age in the UK is 9 years [3], suggesting participants may struggle with the information provided.

Stakeholder engagement to identify priorities for improving the quality and value of care provided to critically ill patients
H Stelfox1, E McKenzie1, S Bagshaw1, M Gill1, P Oxland1, D Boulton1, D Osweill1, M Potestio1, D Niven1
1University of Calgary, AB, Canada; 2University of Alberta, Edmonton, AB, Canada

Introduction
Healthcare systems do not make optimal use of evidence, which results in suboptimal patient care. Large amounts of scientific evidence are generated but not implemented into patient care (knowledge to care gap). We sought to identify and prioritize knowledge to care gaps in critical care medicine as opportunities to improve quality and value in care.

Methods
Using a modified RAND/UCLA Appropriateness Methodology, a committee of 38 providers and decision-makers representing a population-based clinical network of adult (n = 14) and pediatric (n = 2) medical-surgical ICUs in Alberta, Canada (population 4 million) serially proposed, rated and revised potential knowledge to care gaps as priorities for improvement. The priorities developed by the committee were sent to the network’s 1,790 frontline providers to rate their importance. The final list of priorities that were rated as important was disseminated to all network members for feedback.

Results
Sixty-eight knowledge to care gaps were proposed, rated and revised by the committee over three rounds of review, resulting in 13 priorities for improvement. Then, 1,103 providers (62% response rate) representing nurses, respiratory therapists, allied health professionals and physicians evaluated the priorities and rated nine as necessary. In multivariable logistic regression analyses, provider (profession, experience and teaching status of ICU) and knowledge to care gap characteristics (strength of supporting evidence, potential to benefit the patient, potential to improve patient/family experience, and potential to decrease costs) were associated with priorities rated as necessary. After disseminating the results to all network members, 627 responded (35% response rate) and indicated that the priorities were reasonable choices for quality improvement initiatives (87%), that they were highly supportive of working on initiatives targeting the priorities (61%) and would be willing to act as local champions for the initiatives (n = 92 individuals).

Conclusion
Our research approach engaged a diverse group of stakeholders to identify nine priorities for improving the quality and value of care provided to critically ill patients. This methodology can be used to engage stakeholders and identify priorities for quality improvement in other healthcare systems and domains. Additional work is required to reconcile provider/decision-maker and patient/family priorities.

P575
Using patient researchers to understand patient and family experiences in ICUs
H Stelfox1, E McKenzie1, S Bagshaw1, M Gill1, P Oxland1, D Boulton1, D Osweill1, M Potestio1, D Niven1
1University of Calgary, AB, Canada; 2University of Alberta, Edmonton, AB, Canada

Introduction
With increasing emphasis on patient and family-centred care, it follows that patients and their family members should be included when priorities for improving care are established. We therefore used a novel methodology that employs former patients and family members as researchers to describe the experiences of critically ill patients and their families with ICUs and to identify opportunities for improvement.

Methods
Using the patient engagement framework developed by Marlett and Emes, we engaged four former patients and family members trained in qualitative research methods to conduct and analyse semistructured focus groups and interviews with adult patients who had recovered from critical illness and family members of both surviving and deceased patients. Participants were recruited from 13 ICUs in Alberta, Canada. Focus groups and interviews were recorded, transcribed and analysed using phenomenological reduction. Data collection continued until thematic saturation was reached.

Results
Thirty-two participants including patients (n = 11) and family members (n = 21) participated in five focus groups (n = 23 participants) and eight interviews (n = 9 participants). Participants articulated themes reflecting important components of care organised across three phases of the ICU experience; admission to ICU, daily care in ICU and after ICU discharge. Admission to ICU comprised three themes: patient and family transition into ICU, patient and family disorientation upon admission to ICU and preferred staff actions to help patients/family adapt to the ICU. The daily care phase of ICU consisted of five themes: honouring patient’s voices, needing to know, making decisions, culture in ICU and medical care. The experience after ICU discharge comprised two themes: transition from ICU to a hospital ward and long-term effects of critical illness. Participants identified five
Since 2012 our unit has introduced a consultant-led family ward involvement and satisfaction in the provision of care for the critically ill. There is now increasing recognition of the importance of family centred care, and engaging them as researchers is a viable strategy to identify opportunities for quality improvement that are patient and family centred.

**P576**

**Survey of visiting hours in critical care units in English trauma centres**

E Taylor, N Bunker
The Royal London Hospital, London, UK

The purpose of this study was to assess the visiting restrictions placed on families visiting adult patients on critical care units within trauma hospitals in England. Whilst it is well recognised that high-quality care for patients is of paramount importance, we should also be aware that supporting patients’ families offers long-term benefits for patient, family and hospital. In our own unit we are reviewing whether we could adopt a more flexible attitude to visiting times and assessing how to provide a more welcoming environment to relatives. To inform our own review and in order to develop a best practise approach, we surveyed all of the major trauma centres in England.

**Methods** A telephone survey on visiting times was conducted in 53 adult critical care units in trauma centres in England. A list of trauma centres was obtained from the NHS England website. All critical care units (other than obstetric high dependency units and coronary care units, unless part of a cardiothoracic critical care unit) within each hospital were surveyed. Each respondent was asked about the visiting hours, whether children were allowed to visit and how many visitors to the whole of England were surveyed: there was a 100% response rate. Visiting hours varied between hospitals and between units within the same hospital. Nine units (17%) had open visiting hours, although most gave advice on times to avoid such as nursing handover. The majority of units (44.83%) operated restricted visiting with a median (range) of 6 (2 to 9) hours. All units allowed a maximum of two visitors to the bedspace. Children were allowed in nine units without restriction, the remaining units advised that it may not be appropriate for children to visit and it was at the discretion of the parents and medical staff.

**Results** Fifty-three units with between four and 75 beds and covering the whole of England were surveyed: there was a 100% response rate. Visiting hours varied between hospitals and between units within the same hospital. Nine units (17%) had open visiting hours, although most gave advice on times to avoid such as nursing handover. The majority of units (44.83%) operated restricted visiting with a median (range) of 6 (2 to 9) hours. All units allowed a maximum of two visitors to the bedspace. Children were allowed in nine units without restriction, the remaining units advised that it may not be appropriate for children to visit and it was at the discretion of the parents and medical staff.

**Conclusion** The majority of adult critical care units in England, including our own, have restricted visiting policies. Visiting policies are a source of debate amongst staff in intensive care with concerns about open visiting including increased workload and interruptions to normal routine [1]. This is consistent with the views of staff at our own unit who, in appreciative enquiry, have expressed mixed opinions about extending visiting times. Extending visiting times is only part of a wider project to improve the way relatives experience intensive care whilst ensuring both medical and nursing staff feel supported, creating an environment for optimal communication.

**Bereavement care in UK ICUs: a national survey**

M Berry¹, E Brink², V Metaxa²
¹Imperial Healthcare Trust, London, UK; ²King’s College Hospital, London, UK

Introduction For the families of critically ill patients, the death of a loved one in the ICU is often an unexpected and traumatic event, characterised by difficult decisions regarding withholding or withdrawing life-sustaining therapy. Increasingly the importance of bereavement care (BC) in the ICU is being acknowledged, although reports continue to highlight the inadequacies around end-of-life care in the critical care environment. In 1998, the Intensive Care Society (ICS) published guidelines mapping out BC in the ICU [1]. We aimed to compare BC in ICUs across England against the recommendations set out by the ICS.

**Methods** All adult ICUs in England were contacted over a 2-week period, using a standardised questionnaire based on the nine domains identified by the ICS. All answers were collected anonymously using SurveyMonkey®. An 80% compliance rate was deemed acceptable.

**Results** From the 148 ICUs identified, 113 answered the questionnaire (76%). Forty-three per cent of the responders had access to training in BC and in communication skills, and 54% had a named member of staff responsible for training, writing, auditing and developing the round (FWR), to enhance and standardise communication and improve satisfaction. Following introduction of the FWR we have audited family satisfaction using the validated FS-ICU questionnaire [1].

**Conclusion** Patients completing their critical care episode. The questionnaire was completed anonymously and data collected. This was a pragmatic study, no changes were made to communication strategies.

**Results** There is a high degree of satisfaction across all domains of the FS-ICU including treatment of family and provision of information (Figure 1). One hundred per cent found FWR to be helpful, only 55% had anticipated this. Fifteen per cent changed their perception of critical care. It enabled 15% to raise new concerns. One hundred per cent were able to have questions answered satisfactorily. Linked to the FS-ICU, we have seen marked improvements in decision-making and satisfaction.

**Reference**

BC policy. When asked about the presence of a written BC policy only 45% responded positively, and even less (19%) had provisions for audit and development of the service. Information to staff about cultural and religious rites around the time of death, and to relatives on what to do after a death was available in 81% and 96% respectively. The general practitioner was informed of the deaths taking place in the ICU in 77% of the cases. In more than 70% of the participating ICUs, efforts were made to ensure privacy of the grieving relatives and to have dedicated follow-up facilities for the bereaved. Even though staff support programmes were recognised as paramount, only 54% of the ICUs had formal ones set up.

**Conclusion** This is the first national audit of BC in the ICU since the initial ICS guideline publication. Even though most ICUs provided relatives with information around the time of death, training, auditing and adequate facilities do not meet the recommended standards. The lack of adherence is definitely multifactorial and requires further research. In the meantime, vigorous implementation of these guidelines is warranted in order to ensure optimal care for the bereaved families.
