Supporting Information

ABSTRACT: We report a scalable, one-pot Mannich route to enantioenriched α-amino esters by direct reaction of α-chloroglycine ester as a practical imino ester surrogate. The reaction is promoted by a chiral aminothiourea, which is proposed to operate cooperatively by generating an iminium ion by chloride abstraction and an enolate by deprotonation, followed by highly stereoselective C–C bond formation between both reactive intermediates associated non-covalently within the catalyst framework.

The Mannich reaction involves the enantioselective addition of enolate equivalents to aldehydes or ketones to produce β-amino esters. Practical, asymmetric methods have been enabled by the identification of various chiral metal and organic catalysts. Mannich reactions involving N-carbamoyl imino esters as electrophilic partners afford chiral carbamate-protected α-amino esters directly, and this represents a most attractive route to this important class of products. However, the instability of imino esters, which require cumbersome preparation and strictly controlled conditions in catalytic reactions, is an inherent limitation. To counter this obstacle, α-haloglycine esters and α-amido sulfones have been exploited as imine surrogates in Mannich-type reactions (Scheme 1). These systems, however, require multi-pot operations and use of excess base for the generation of imine. To overcome these limitations, we envisioned the application of chiral bifunctional catalysts capable of both generating imine from its surrogate and inducing asymmetric addition of the enolate.

The use of chiral thioureas to promote anion abstraction from neutral organic electrophiles to generate highly reactive cationic intermediates has emerged as a powerful platform in asymmetric catalysis. Recently, the Roche group reported a practical route to α-chloroglycine esters by reaction of carbamates or amides with ethyl glyoxylate, acetyl chloride, and acetic acid in the context of a new route to racemic α-arylglycine esters. We considered whether α-chloroglycine esters prepared in this manner could be engaged directly in thiourea-catalyzed enantioselective Mannich reactions (Scheme 1). Specifically, thiourea-induced chloride abstraction could serve to generate a reactive N-acyliminium ion, while the basic amine functionality could generate and position an enolate for nucleophilic addition to give the desired enantioenriched α-amino esters. We describe here the application of such an anion-binding strategy in a practical Mannich synthesis of aspartic acid derivatives. This methodology circumvents the multi-pot, base-mediated preparation of N-carbamoyl imino esters from imine surrogates developed previously.

We examined the Mannich reactions using N-Cbz α-chloroglycine ethyl ester (1-Cbz) as the model substrate and bifunctional thioureas as potential catalysts. We discovered that Takemoto’s tertiary aminothiourea catalyst promoted the reaction between 1-Cbz and dibenzoxymethane in DCM at −30 °C in the presence of 4 Å molecular sieves (MS), affording the Mannich product in 90% yield and 93% ee (Table 1, entry 1). Thiourea catalysts lacking the tertiary amino group gave no desired product. Substrates bearing other carbamate or acyl N-protecting groups afforded significantly inferior results in comparison to Cbz with respect to reaction enantioselectivity (entries 2–8). Reaction temperature and solvent were also found to exert profound effects on enantioselectivity (entries 1, 9–16). Optimal results were obtained at −30 °C in DCM, with lower temperatures affording no advantage.

We considered whether the stoichiometric HCl byproduct of the Mannich reaction might have a deleterious effect on catalyst performance by forming a salt with its tertiary amine moiety. Indeed, the HCl salt of 2 catalyzes formation of 3a in only 21% yield and 18% ee under the conditions of the model reaction (Table 2, entries 1 and 2). We explored whether added bases
could serve to regenerate active catalyst 2 from the HCl salt. While inorganic bases conferred no improvement on reaction performance, introduction of Et3N (0.5 equiv) to the reaction with 2-HCl resulted in formation of 3a in 76% yield and 84% ee (entry 3). Addition of Et3N to the reaction with the free base had a striking, positive effect, with formation of 3a in 95% yield and 99% ee (entries 1 vs 4). Ultimately, it was found that addition of 25 mol% of Et3N was sufficient to obtain optimal results (entry 5). Reduction of the catalyst loading or omission of 4 Å MS had a deleterious effect on both yield and ee (entries 6 and 7).

A variety of 1,3-diketones were found to participate effectively in enantioselective Mannich reactions with 1-Cbz catalyzed by 2 (Table 3). Whereas some variability was observed in reactions carried out over 0.25 mmol scale on 0 °C, consistent and optimal results were obtained at −30 °C. Both symmetrical and unsymmetrical 1,3-dialkyl-diketones afforded products in high ee (3a, 3e, 3f). α-Fluorinated β-diketones also underwent highly enantioselective reactions (3d, 3g). A nearly statistical mixture of diastereomers was obtained in the case of 3g, which bears a non-epimerizable β-carbonyl stereocenter. Unsymmetrical alkyl-aryl diketones were also found to be compatible substrates for the enantioselective reaction (3b); however, aliphatic 1,3-diketone underwent reaction with 1-Cbz with lower ee (3c).

<sup>a</sup>Conditions: substrate (0.25 mmol), catalyst (10 mol%), diketone (0.5 mmol), 4 Å MS (40 mg), Et3N (25 mol%), DCM (5 mL), under N2, initially cooled to −78 °C and stirred at −30 °C, 36 h. <sup>b</sup>The yield was determined by 1H NMR and HPLC analyses of the crude product. <sup>c</sup>Absolute configuration assigned by analogy to product 4h (Table 4).

Reactions of 1-Cbz with β-ketoesters proceeded to afford Mannich products with moderate-to-high enantioselectivity (Table 4).<sup>17,18</sup> The resulting ketodiesters may be subjected to decarboxylation to reveal valuable β-keto α-amino acid derivatives.<sup>19</sup> In particular, products bearing electron-neutral or -deficient aryl ketone groups (4a, 4c–k) were obtained with generally good yields and ≥89% ee. Whereas variation of the size of the ester substituent had little impact on the reaction outcome (e.g., 4a vs 4g, 4i vs 4j), the use of benzhydryl esters had a significant positive effect on reaction enantioselectivity (e.g., 4a vs 4h). This latter effect made it possible to obtain alkyl ketone products in high ee and good yield (4k).

The practicality of this protocol was demonstrated in the sequential preparation of N-Cbz α-chloroglycine ester (1-Cbz) and enantioselective Mannich reaction in a one-pot protocol on a preparative scale (Scheme 2). As reported previously,<sup>11</sup> 1-Cbz could be prepared in nearly quantitative yield from commercial feedstock molecules. Removal of AcOH and AcCl from the product mixture of 1-Cbz under reduced pressure was found to be essential for the subsequent Mannich reaction. Reaction of
The tertiary amine moiety in the aminothiourea catalyst abstracts chloride from the electrophilic intermediate. Two possible mechanistic pathways involving thiourea activation of the electrophilic intermediate are outlined in Scheme 3. In the anion abstraction pathway, the thiourea catalyst abstracts chloride from the electrophilic intermediate (A). Reaction of the tertiary amine moiety in A with the β-dicarbonyl compound (dibenzoylmethane in the scheme) generates the amine-bound enolate (B), which attacks the nearby iminium ion in an enantioselective manner to give the Mannich product 3a. The plausibility of this mechanism would require that the highly acidic iminium ion intermediate not interfere with the generation and addition of the enolate. An alternative reaction pathway involving the formation of a thiourea-bound N-Cbz iminoester intermediate (C) generated by the reaction between the catalyst’s tertiary amine moiety and 1-Cbz must therefore also be considered, although the mechanism of enolate generation is less evident in this pathway.

Regardless of the specific mechanism of catalysis, it is clear that interactions involving aromatic substituents on the substrates play a critical role in modulating both reactivity and enantioselectivity. Replacement of aryl groups for alkyl groups in the 1,3-diketone substrates leads to sizable decreases in enantioselectivity and product yield (Table 4, 4f→4g). Further elucidation of the specific catalyst–substrate interactions at play in these reactions is a subject of ongoing interest in our laboratories.

In summary, we have developed an efficient thiourea-catalyzed enantioselective Mannich reaction that provides access to a variety of N-carbamoyl α-amino esters. The products can be obtained using a one-pot protocol on a preparative scale from commercial substrates and catalyst. Further application of 1-Cbz and related substrates in asymmetric catalysis with H-bond donor catalysts is currently underway.

Table 4. Asymmetric Synthesis of Aspartic Acid Derivatives

| Conditions: substrate (0.25 mmol), catalyst (10 mol%), β-ketoester (0.5 mmol), 4 Å MS (40 mg), Et₃N (25 mol%), DCM (5 mL), under N₂, initially cooled to −78 °C and stirred at −30 °C, 36 h. Isolated yield. Products were isolated as the thermodynamic mixtures of diastereomers. The structure and absolute configuration of 4h was established by X-ray crystallography, and the stereochemistry of all other products was assigned by analogy.

Scheme 2. Large-Scale, One-Pot Synthesis of 3a

1-Cbz with 1,3-diphenyl-1,3-propanedione in the presence of 10 mol% catalyst afforded 3a in 97% overall yield and 97% ee. This two-step, one-pot synthesis of highly enantioenriched unnatural amino esters is accomplished using commercially available substrates and catalyst, and generates only AcOH, HCl, and Et₃N-HCl as byproducts.

The potential mechanisms by which this enantioselective Mannich reaction of α-chloroglycine esters proceeds merit consideration. No measurable background reaction between 1-Cbz and dibenzoylmethane is observed in the absence of the thiourea catalyst, either with or without added Et₃N. This observation suggests an essential role of the H-bond donor groups in the 1,3-diketone substrates leads to sizable decreases in enantioselectivity and product yield (Table 4, 4f→4g). Further elucidation of the specific catalyst–substrate interactions at play in these reactions is a subject of ongoing interest in our laboratories.

In summary, we have developed an efficient thiourea-catalyzed enantioselective Mannich reaction that provides access to a variety of N-carbamoyl α-amino esters. The products can be obtained using a one-pot protocol on a preparative scale from commercial substrates and catalyst. Further application of 1-Cbz and related substrates in asymmetric catalysis with H-bond donor catalysts is currently underway.
