Abstract

We present numerical studies of fermion and boson models with random all-to-all interactions (the SYK models). The high temperature expansion and exact diagonalization of the $N$-site fermion model are used to compute the entropy density: our results are consistent with the numerical solution of $N = \infty$ saddle point equations, and the presence of a non-zero entropy density in the limit of vanishing temperature. The exact diagonalization results for the fermion Green’s function also appear to converge well to the $N = \infty$ solution. For the hard-core boson model, the exact diagonalization study indicates spin glass order. Some results on the entanglement entropy and the out-of-time-order correlators are also presented.
I. INTRODUCTION

Fermion and boson models with infinite-range random interactions were studied in the 1990’s and later [1–6] as models of quantum systems with novel non-Fermi liquid or spin glass ground states. More recently, it was proposed that such models are holographically connected to the dynamics of AdS$_2$ horizons of charged black holes [7, 8], and remarkable connections have emerged to topics in quantum chaos and black hole physics [9–15].

The model introduced by Sachdev and Ye [1] was defined on $N$ sites, and each site had particles with $M$ flavors; then the double limit $N \to \infty$, followed by $M \to \infty$. In such a limit, the random interactions depend on 2 indices, each taking $N$ values. Taking the double limit is challenging in numerical studies, and so they have been restricted to $M = 2$ with increasing values of $N$ [5, 6]. It was found that the ground state for $N \to \infty$ at a fixed $M = 2$ was almost certainly a spin glass. So a direct numerical test of the more exotic non-Fermi liquid states has not so far been possible.

Kitaev [9] has recently introduced an alternative large $N$ limit in which the random interaction depends upon 4 indices, each taking $N$ values; the saddle-point equations in the $N \to \infty$ limit are the same as those in Ref. 1. No separate $M \to \infty$ is required, and this is a significant advantage for numerical study. The present paper will study such Sachdev-Ye-Kitaev (SYK) models by exact diagonalization; some additional results will also be obtained in a high temperature expansion. Our numerical studies will be consistent the fermionic SYK model displaying a non-Fermi liquid state which has extensive entropy, and entanglement entropy, in the zero temperature limit. For the case of the bosonic SYK model, our numerical study indicates spin-glass order: this implies that the analytic study of the large $N$ limit will require replica symmetry breaking [3].

The outline of this paper is as follows. In Section II, we review the large $N$ solution of the SYK model, and present new results on its high temperature expansion. In Section III we present exact diagonalization results for the fermionic SYK model, while the hard-core boson case is considered later in Section V. Section IV contains a few results on out-of-time-order correlators of recent interest.

II. LARGE $N$ LIMIT FOR FERMIONS

This section will introduce the SYK model for complex fermions, and review its large $N$ limit. We will obtain expressions for the fermion Green’s function and the free energy density. A high temperature expansion for these quantities will appear in Section II.B.
The Hamiltonian of the SYK model is

\[ H = \frac{1}{(2N)^{3/2}} \sum_{i,j,k,t=1}^{N} J_{ij;kt} c_i^\dagger c_j^\dagger c_k c_t - \mu \sum_i c_i^\dagger c_i \]  

(1)

where the \( J_{ij;kt} \) are complex Gaussian random couplings with zero mean obeying

\[ J_{ji;kt} = -J_{ij;kt}, \quad J_{ij;tk} = -J_{ij;kt}, \quad J_{ij;ij} = J_{ij;kt}^* \]

\[ \sqrt{\sum J_{ij;kt}^2} = J. \]  

(2)

The above Hamiltonian can be viewed as a ‘matrix model’ on Fock space, with a dimension which is exponential in \( N \). But notice that there are only order \( N^4 \) independent matrix elements, and so Fock space matrix elements are highly correlated. The conserved U(1) density, \( Q \) is related to the average fermion number by

\[ Q = \frac{1}{N} \sum_i \langle c_i^\dagger c_i \rangle. \]  

(3)

The value of \( Q \) can be varied by the chemical potential \( \mu \), and ranges between 0 and 1. The solution described below applies for any \( \mu \), and so realizes a compressible state.

Using the imaginary-time path-integral formalism, the partition function can be written as

\[ Z = \int Dc^\dagger Dc \exp (-S) \]  

(4)

where

\[ S = \int_0^\beta d\tau (c^\dagger \partial_\tau c + H), \]  

(5)

where \( \beta = 1/T \) is the inverse temperature, and we have already changed the operator \( c \) into a Grassman number.

In the replica trick, we take \( n \) replicas of the system and then take the \( n \to 0 \) limit

\[ \ln Z = \lim_{n \to 0} \frac{1}{n} (Z^n - 1) \]  

(6)

Introducing replicas \( c_{ia} \), with \( a = 1 \ldots n \), we can average over disorder and obtain the replicated imaginary time (\( \tau \)) action

\[ S_n = \sum_{ia} \int_0^\beta d\tau c_{ia}^\dagger \left( \frac{\partial}{\partial \tau} - \mu \right) c_{ia} - \frac{J^2}{4N^3} \sum_{ab} \int_0^\beta d\tau d\tau' \left| \sum_i c_{ia}(\tau) c_{ib}(\tau') \right|^4; \]  

(7)

(here we neglect normal-ordering corrections which vanish as \( N \to \infty \)). Then the partition function can be written as

\[ Z^n = \int \prod_a Dc_a^\dagger Dc_a \exp (-S_n) \]  

(8)
If we ignore the time-derivative term in Eq. (7), notice that the action has a SU(N) gauge invariance under \( c_{ia} \rightarrow U_{ij}(\tau)c_{ja} \). And indeed, in the low energy limit leading to Eq. (20), the time-derivative term can be neglected. However, we cannot drop the time-derivative term at the present early stage, as it plays a role in selecting the manner in which the SU(N) gauge invariance is ‘broken’ in the low energy limit. In passing, we note that this phenomenon appears to be analogous to that described in the holographic study of non-Fermi liquids by DeWolfe et al. [16]: there, the bulk fermion representing the low energy theory is also argued to acquire the color degeneracy of the boundary fermions due to an almost broken gauge invariance. As in Ref. [16], we expect the bulk degrees of freedom of gravitational duals to the SYK model to carry a density of order \( N \leq 10 \).

Following the earlier derivation [1], we decouple the interaction by two successive Hubbard-Stratonovich transformations. First, we introduce the real field \( Q_{ab}(\tau, \tau') \) obeying

\[
Q_{ab}(\tau, \tau') = Q_{ba}(\tau', \tau). \tag{9}
\]

The equation above is required because the action is invariant under the reparameterization \( a \leftrightarrow b, \tau \leftrightarrow \tau' \). In terms of this field

\[
S_n = \sum_{ia} \int_0^\beta d\tau c^\dagger_{ia} \left( \frac{\partial}{\partial \tau} - \mu \right) c_{ia} + \sum_{ab} \int_0^\beta d\tau d\tau' \left\{ \frac{N}{4J^2} \left[ Q_{ab}(\tau, \tau') \right]^2 - \frac{1}{2N} Q_{ab}(\tau, \tau') \left| \sum_i c^\dagger_{ia}(\tau)c_{ib}(\tau') \right|^2 \right\}. \tag{10}
\]

A second decoupling with the complex field \( P_{ab}(\tau, \tau') \) obeying

\[
P_{ab}(\tau, \tau') = P^*_{ba}(\tau', \tau) \tag{11}
\]

yields

\[
S_n = \sum_{ia} \int_0^\beta d\tau c^\dagger_{ia} \left( \frac{\partial}{\partial \tau} - \mu \right) c_{ia} + \sum_{ab} \int_0^\beta d\tau d\tau' \left\{ \frac{N}{4J^2} \left[ Q_{ab}(\tau, \tau') \right]^2 + \frac{N}{2} Q_{ab}(\tau, \tau') \left| P_{ab}(\tau, \tau') \right|^2 - Q_{ab}(\tau, \tau')P_{ba}(\tau', \tau) \sum_i c^\dagger_{ia}(\tau)c_{ib}(\tau') \right\}. \tag{12}
\]

Now we study the saddle point of this action in the large \( N \) limit. Using

\[
\int [d\phi] \frac{\delta F[\phi]}{\delta \phi(x)} = 0 \tag{13}
\]

Taking \( F = \exp(-S_n) \) and \( \phi = P_{ba} \) we obtain

\[
P_{ab}(\tau, \tau') = \frac{1}{N} \langle c^\dagger_{ia}(\tau)c_{ib}(\tau') \rangle \tag{14}
\]
Note that we have combined \( \frac{N}{2} Q_{ab} |P_{ab}|^2 \) and \( \frac{N}{2} Q_{ba} |P_{ba}|^2 \) as one term. Similarly, taking derivative with respect to \( Q_{ab} \), we have

\[
Q_{ab}(\tau, \tau') = J^2 |P_{ab}(\tau, \tau')|^2.
\]

(15)

If we only consider diagonal solution in the replica space (non spin-glass state), we can define the self energy:

\[
\Sigma(\tau, \tau') = -Q(\tau, \tau')P(\tau', \tau),
\]

(16)

and the Green’s function

\[
G(\tau, \tau') = -\langle T_\tau c(\tau)c^\dagger(\tau') \rangle.
\]

(17)

Then we have

\[
P(\tau, \tau') = G(\tau', \tau),
\]

(18)

and the saddle point solution becomes

\[
G(i\omega_n) = \frac{1}{i\omega_n + \mu - \Sigma(i\omega_n)},
\]

\[
\Sigma(\tau) = -J^2 G^2(\tau) G(-\tau)
\]

(19)

The above equation shows a re-parameterization symmetry at low temperature if we ignore the \( i\omega_n \) term [9, 10]. At zero temperature, the low energy Green’s function is found to be[1, 10]

\[
G(z) = Ce^{-i(\pi/4+\theta)}\sqrt{z}, \quad \text{Im}(z) > 0, \ |z| < J, \ T = 0
\]

(20)

where \( C \) is a positive number, and \(-\pi/4 < \theta < \pi/4\) characterizes the particle-hole asymmetry. A full numerical solution for Eq. (19) at zero temperature was also obtained in Ref. 1, and is shown in Fig. 1. We can see the \( 1/\sqrt{z} \) behavior at low energy. However, it is not possible to work entirely within this low energy scaling limit to obtain other low temperature properties: the \( i\omega_n \) term is needed to properly regularize the ultraviolet, and select among the many possible solutions of the low-energy equations [4, 10].

**A. Free energy and thermal entropy**

The free energy is defined to be

\[
\mathcal{F} = -\frac{1}{\beta} \ln Z_{\text{eff}}
\]

(21)

where \( Z_{\text{eff}} \) has only one replica. So

\[
Z_{\text{eff}} = \int Dc^\dagger Dc \exp(-\mathcal{S}),
\]

(22)
FIG. 1. Figure, adapted from Ref 1, showing the imaginary part of Green’s function multiplied by $\sqrt{\omega}$ as a function of $\omega$ at particle-hole symmetric point $\theta = 0$. Our definition of the Green’s function, Eq. (17), differs by a sign from Ref. [1].

with

$$S = \sum_i \int_0^\beta d\tau d\tau' c_i^\dagger(\tau) \left( \frac{\partial}{\partial \tau} \delta(\tau - \tau') - \mu \delta(\tau - \tau') + \Sigma(\tau, \tau') \right) c(\tau')$$
$$+ \int_0^\beta d\tau d\tau' \left\{ \frac{1}{4J^2} \left[ \Sigma(\tau, \tau')/G(\tau, \tau') \right]^2 - \frac{1}{2} \Sigma(\tau, \tau') G(\tau', \tau) \right\}$$

For the free energy density $F/N$, we can just drop the site index $i$ to give the single site action, substituting the Green’s function and self energy

$$S = \int_0^\beta d\tau d\tau' c^\dagger(\tau) \left( \frac{\partial}{\partial \tau} \delta(\tau - \tau') - \mu \delta(\tau - \tau') + \Sigma(\tau, \tau') \right) c(\tau')$$
$$+ \int_0^\beta d\tau d\tau' \left\{ \frac{1}{4J^2} \left[ \Sigma(\tau, \tau')/G(\tau, \tau') \right]^2 - \frac{1}{2} \Sigma(\tau, \tau') G(\tau', \tau) \right\}$$

After integrating out the fermion field

$$S = - \text{Tr} \ln \left[ (\partial_{\tau} - \mu) \delta(\tau - \tau') + \Sigma(\tau, \tau') \right] + \int_0^\beta d\tau d\tau' \left\{ \frac{1}{4J^2} \left[ \Sigma(\tau, \tau')/G(\tau, \tau') \right]^2 - \frac{1}{2} \Sigma(\tau, \tau') G(\tau', \tau) \right\}$$
To verify this result, we can vary with respect to $\Sigma(\tau, \tau')$ and $G(\tau, \tau')$, also using the fact that $\Sigma(\tau, \tau') = \Sigma^*(\tau', \tau)$, $G(\tau, \tau') = G^*(\tau', \tau)$, to obtain the equations of motions as before.

In the large $N$ limit, we can substitute in the classical solution, and then free energy density is

$$\frac{\mathcal{F}}{N} = T \sum_n \ln (-\beta G(i\omega_n)) - \int_0^\beta d\tau \frac{3}{4} \Sigma(\tau)G(-\tau)$$

(26)

The thermal entropy density can be obtained by

$$\frac{S}{N} = -\frac{1}{N} \frac{\partial \mathcal{F}}{\partial T}$$

(27)

B. High temperature expansion

Now we present a solution of Eqs. (19) by a high temperature expansion (HTE). Equivalently, this can be viewed as an expansion in powers of $J$.

We will limit ourselves to the simpler particle-hole symmetric case, $Q = 1/2$, for which both $G$ and $\Sigma$ are odd functions of $\omega_n$. We start with the high temperature limit

$$G_0(i\omega_n) = \frac{1}{i\omega_n}$$

(28)

and then expand both $G$ and $\Sigma$ in powers of $J^2$: $G = G_0 + G_1 + \cdots$ and $\Sigma = \Sigma_0 + \Sigma_1 + \cdots$. The successive terms can be easily obtained by iteratively expanding both equations in Eq. (19), and repeatedly performing Fourier transforms between frequency and time.

$$\Sigma_1(i\omega_n) = J^2 \frac{1}{4i\omega_n}$$

$$G_1(i\omega_n) = J^2 \frac{1}{4(i\omega_n)^3}$$

$$\Sigma_2(i\omega_n) = J^4 \frac{3}{16(i\omega_n)^3}$$

$$G_2(i\omega_n) = J^4 \frac{1}{4(i\omega_n)^5}$$

$$\Sigma_3(i\omega_n) = J^6 \left[ \frac{15}{32(i\omega_n)^5} + \frac{3}{128T^2(i\omega_n)^3} \right]$$

$$G_3(i\omega_n) = J^6 \left[ \frac{37}{64(i\omega_n)^7} + \frac{3}{128T^2(i\omega_n)^5} \right]$$

$$\Sigma_4(i\omega_n) = J^8 \left[ \frac{561}{256(i\omega_n)^7} + \frac{75}{512T^4(i\omega_n)^5} - \frac{1}{256T^4(i\omega_n)^3} \right]$$

$$G_4(i\omega_n) = J^8 \left[ \frac{5}{2(i\omega_n)^9} + \frac{81}{512T^2(i\omega_n)^7} - \frac{1}{256T^4(i\omega_n)^5} \right]$$

(29)
The free energy density can be written in terms of $G(i\omega_n)$ and $\Sigma(i\omega_n)$

$$\frac{\mathcal{F}}{N} = T \sum_n \ln(-\beta G(i\omega_n)) - \frac{3T}{4} \sum_n \Sigma(i\omega_n) G(i\omega_n)$$

We also need to regularize the above free energy by subtracting and adding back the free particle part

$$\frac{\mathcal{F}}{N} = -T \ln 2 + T \sum_n [\ln(-\beta G(i\omega_n)) - \ln(-\beta i\omega_n)] - \frac{3T}{4} \sum_n \Sigma(i\omega_n) G(i\omega_n)$$

The series expansion of the entropy density is

$$\frac{S}{N} = \ln 2 - \frac{1}{64} \frac{J^2}{T^2} + \frac{1}{512} \frac{J^4}{T^4} - \frac{11}{3684} \frac{J^6}{T^6} + \frac{599}{11796480} \frac{J^8}{T^8} + \cdots$$

Next, we describe our numerical solution of Eq. (19) at non-zero temperature. We used a Fourier transform (FT) to iterate between the two equations, until we obtained a convergent solution. For faster convergence, we started at high temperature, and used the above high temperature expansion as the initial form. Then we decreased temperature to get the full temperature dependence. We compare the large $N$ exact numerical result with the high temperature expansion in Fig. 2. At high temperatures, all methods converge to $\ln 2$ as expected. The HTE results fit the exact numerics quite well for $T/J > 0.6$, but are no longer accurate at lower $T$. The exact numerics shows a finite entropy density in the limit of vanishing temperature, with a value consistent with earlier analytic results [4][10].
FIG. 2. Entropy computation from exact large $N$ EOM and HTE: at high temperature, all approaches the infinite temperature limit $S/N = \ln 2$. HTE result fits the exact result quite well for $T/J > 0.6$.

III. EXACT DIAGONALIZATION FOR FERMIONS

We now test the validity of the large $N$ results by comparing with an exact diagonalization (ED) computation at finite $N$. For the numerical setup, it was useful to employ the Jordan-Wigner transformation to map the Hamiltonian to a spin model

$$c_i = \sigma_i^+ \prod_{j<i} \sigma_j^z, \quad c_i^\dagger = \sigma_i^- \prod_{j<i} \sigma_j^z$$

We built a matrix of the $N$ spins and diagonalized it numerically. After obtaining the full spectrum, we obtained both the imaginary part of Green’s function and thermal entropy, and our results are compared with the large $N$ results in Fig. 1 and Fig. 2.

In this note, we focus on the particle-hole symmetric point. But particle-hole symmetry does not correspond to the point $\mu = 0$ in the Hamiltonian Eq. (1), because there are quantum corrections to the chemical potential $\delta \mu \sim O(N^{-1})$ coming from the terms in which $i, j, k, l$ are not all different from each other, because these terms are not particle-hole symmetric. So we use a Hamiltonian with extra correction terms that compensate $\delta \mu$:

$$H = \frac{1}{(2N)^{3/2}} \sum_{i,j,k,l=1}^N J_{ij:kl} (c_i^\dagger c_j^\dagger c_k c_\ell + \delta_{ik} n c_j^\dagger c_\ell - \delta_{il} n c_j^\dagger c_k - \delta_{jk} n c_i^\dagger c_\ell + \delta_{jl} n c_i^\dagger c_k),$$

(34)
where we use $n = 1/2$ for the particle-hole symmetric case.

We define the on-site retarded Green’s function by

$$G^R_i(t, t') = -i\theta(t - t') \langle \{c_i(t), c^\dagger_i(t')\} \rangle.$$  \hspace{1cm} (35)

Using Lehmann representation

$$G^R_i(\omega) = \frac{1}{Z} \sum_{nn'} \frac{\langle n|c_i|n'\rangle \langle n'|c^\dagger_i|n\rangle}{\omega + E_n - E_{n'} + i\eta} (e^{-\beta E_n} + e^{-\beta E_{n'}}),$$ \hspace{1cm} (36)

at zero temperature, we obtain

$$G^R_i(\omega) = \sum_{n'} \frac{\langle 0|c_i|n'\rangle \langle n'|c^\dagger_i|0\rangle}{\omega + E_0 - E_{n'} + i\eta} + \frac{\langle 0|c^\dagger_i|n'\rangle \langle n'|c_i|0\rangle}{\omega - E_0 + E_{n'} + i\eta}.$$ \hspace{1cm} (37)

Using $(\omega + i\eta)^{-1} = \mathcal{P} \frac{1}{\omega} - i\pi\delta(\omega)$

$$\text{Im}G^R_i(\omega) = -\pi \sum_{n'} \left[ \langle 0|c_i|n'\rangle \langle n'|c^\dagger_i|0\rangle \delta(\omega + E_0 - E_{n'}) + \langle 0|c^\dagger_i|n'\rangle \langle n'|c_i|0\rangle \delta(\omega - E_0 + E_{n'}) \right].$$ \hspace{1cm} (38)

Numerically, we replace the delta function with a Lorentzian by taking a small $\eta$:

$$\delta(E_0 - E_{n'} + \omega) = \lim_{\eta \to 0^+} \frac{1}{\pi} \frac{\eta}{(E_0 - E_{n'} + \omega)^2 + \eta^2}.$$ \hspace{1cm} (39)

A subtlety in the above numerics, when $\mu = 0$, is the presence of an anti-unitary particle-hole symmetry. The ground state turns out to be doubly degenerate for some system sizes. If so, we will have two ground states $|0\rangle$ and $|0'\rangle$ in the expression of $G^R_i(\omega)$, and we need to sum them up to get the correct Green’s function.

To better understand this degeneracy, we can define the particle-hole transformation operator

$$P = \prod_i (c^\dagger_i + c_i)K$$ \hspace{1cm} (40)

where $K$ is the anti-unitary operator. One can show that it is a symmetry of our Hamiltonian Eq. (34), $[H, P] = 0$. When the total site number $N$ is odd, we know any eigenstate $|\Psi\rangle$ and its particle-hole partner $P|\Psi\rangle$ must be different and degenerate. For even site number, these two states may be the same state. However for $N = 2 \mod 4$, one can show that $P^2 = -1$, and then the degeneracy is analogous to the time-reversal Kramers doublet for $T^2 = -1$ particles. We expect that all the eigenvalues must be doubly degenerate. For $N = 0 \mod 4$, $P^2 = 1$, there is no protected degeneracy in the half filling sector. These facts were all checked by numerics, and carefully considered in the calculation of the Green’s function.
A better understanding of the above facts can be reached from the perspective of symmetry-protected topological (SPT) phases. As shown recently in Ref. 14, the complex SYK model can be thought of as the boundary of a 1D SPT system in the symmetry class AIII. The periodicity of 4 in $N$ arises from the fact that we need to put 4 chains to gap out the boundary degeneracy without breaking the particle-hole symmetry. In the Majorana SYK case, the symmetric Hamiltonian can be constructed as a symmetric matrix in the Clifford algebra $Cl_{0,N-1}$, and the Bott periodicity in the real representation of the Clifford algebra gives rise to a $\mathbb{Z}_8$ classification[14]. Here, for the complex SYK case, we can similarly construct the Clifford algebra by dividing one complex fermion into two Majorana fermions, and then we will have a periodicity of 4.

A. Green’s function

From the above definition of retarded Green’s function, we can relate them to the imaginary time Green’s function as defined in Eq. (17), $G^R(\omega) = G(i\omega_n \rightarrow \omega + i\eta)$. In Fig. 3, we show a

![Graph](image)

FIG. 3. Imaginary part of the Green’s function in real frequency space from large $N$ and exact diagonalization. The inset figure is zoomed in near $\omega = 0$.

comparison between the imaginary part of the Green’s function from large $N$, and from the exact diagonalization computation. The spectral function from ED is particle-hole symmetric for all $N$,
this is guaranteed by the particle-hole symmetry and can be easily shown from the definition of the spectral function Eq. (38). The two results agree well at high frequencies. At low frequencies, the deviations between the exact diagonalization and large \( N \) results get smaller at larger \( N \).

For a quantitative estimate of the deviations between the large \( N \) and exact diagonalization results, we compute the areas under each curve in Fig. 3, and compare their difference:

\[
\Delta \rho = \int d\omega |\text{Im} G_{ED}(\omega) - \text{Im} G_{N=\infty}(\omega)|
\]

(41)

As shown in Fig. 4, the convergence to the \( N = \infty \) limit is slow, possibly with a power smaller than \( 1/N \).

![Fig. 4](attachment:image.png)

**FIG. 4.** The difference of integrated spectral function between ED at different \( N \) and large \( N \) result. The difference appears to be tending to 0 as \( N \) approaches infinity.

**B. Entropy**

We can also compute the finite temperature entropy from ED. The partition function can be obtained from the full spectrum

\[
Z = \sum_n e^{-\beta E_n},
\]

(42)
FIG. 5. Thermal entropy computation from ED, and large $N$. At high temperature, all results the infinite temperature limit $S/N = \ln 2$. At low temperature, all ED results go to zero, but do approach the $N = \infty$ results with increasing $N$. Note that the limits $N \to \infty$ and $T \to 0$ do not commute, and the non-zero entropy as $T \to 0$ is obtained only when the $N \to \infty$ is taken first.

where $E_n$ is the many-body energy, and then free energy density is

$$\frac{F}{N} = -\frac{\beta}{N} \log Z. \quad (43)$$

We can obtain the entropy density from

$$\frac{S}{N} = \frac{1}{N} \frac{\langle E \rangle - F}{T} \quad (44)$$

where $\langle E \rangle = \sum_n \frac{E_n e^{-\beta E_n}}{Z}$ is the average energy.

We use this approach to compute the thermal entropy from the full spectrum, and compare it with the thermal entropy calculated from large $N$ equations of motion Eq. (19). As shown in Fig. 5, the finite size ED computation gives rise to the correct limit $s = \ln 2$ in the high temperature regime, and it agrees with the large $N$ result quite well for $T/J > 0.5$. Although there is a clear trend that a larger system size gives rise to larger thermal entropy at low temperature, we cannot obtain a finite zero temperature entropy for any finite $N$. This is due to the fact that the non-zero zero temperature entropy is obtained by taking the large $N$ limit first then taking the zero temperature limit.
FIG. 6. The difference of integrated thermal entropy between ED at different N and large N result. The difference goes to 0 as 1/N approaches 0.

As in Fig. 4, we estimate the deviation from the large N theory by defining

$$\Delta S = \int dT |S_{ED}(T)/N - S_{N=\infty}(T)/N_{\infty}|,$$

(45)

and plot the result in Fig. 6. The finite size correction goes to 0 as 1/N goes to zero.

C. Entanglement entropy

Finally, we compute the entanglement entropy in the ground state, obtained by choosing a subsystem A of N sites, and tracing over the remaining sites; the results are in Fig. 7. For $N_A < N/2$, we find that $S_{EE}$ is proportional to $N_A$, thus obeying the volume law, and so even the ground state obeys eigenstate thermalization [14]. We would expect that $S_{EE}/N_A$ equals the zero temperature limit of the entropy density $S/N$ [17]. However, our value of $S_{EE}/N_A$ appears closer to ln 2 (see Fig. 7) than the value of $S/N$ as $T \to 0$. Given the small difference between $\ln 2 = 0.69$ and $S/N(T \to 0) = 0.464848...$, we expect this is a finite-size discrepancy.
[FIG. 7. Entanglement entropy for the ground state. We divide the system into two subsystems, A and B, we trace out part B and calculate the entropy for the reduced density matrix $\rho_A$. The x-axis is the size of subsystem A.]

IV. OUT-OF-TIME-ORDER CORRELATIONS AND SCRAMBLING

One of the interesting properties of the SYK model is that it exhibits quantum chaos [9, 13]. The quantum chaos can be quantified in terms of an out-of-time-ordered correlator $\langle A(t)B(0)A(t)B(0)\rangle$ (OTOC) obtained from the cross terms in $\langle [A(t), B(0)]^2 \rangle$ [11]. The exponential decay in the OTOC results in an exponential growth of $\langle [A(t), B(0)]^2 \rangle$ at short times, and the latter was connected to analogous behavior in classical chaos. In particular, Ref. 11, established a rigorous bound, $2\pi/\beta$, for the decay rate, $\lambda_L$, of the OTOC, and the Majorana SYK model is expected [9] to saturate this bound in the strong-coupling limit $\beta J \gg 1$. In the opposite perturbative limit, $\beta J \ll 1$, one expects $\lambda_L \sim J$. Ref. 12 performed a ED calculation of the OTOC on the Majorana SYK model in the infinite temperature limit, $\beta = 0$. Here we will perform a similar calculation on the complex SYK model, and also obtain results at large $\beta J$. We define our renormalized OTOC by

$$\text{OTOC} = -\frac{\langle A(t)B(0)A(t)B(0)\rangle + \langle B(0)A(t)B(0)A(t)\rangle}{2\langle AA\rangle\langle BB\rangle}. \quad (46)$$

We choose the Hermitian Majorana operators $A = c_1 + c_1^\dagger$, $B = c_2 + c_2^\dagger$. The negative sign gives a positive initial value for OTOC. At infinite temperature, the result is shown in Fig. 8. We observe the fast scrambling effect from the quick decay of OTOC, and the early time decay

15
rate $\lambda_L$ is proportional to $J$ as expected. Similar behavior is found in the Majorana SYK model [12]. At finite temperature, although we can perform the computation in the strong coupling limit

\[ \beta J \gg 1, \text{because of finite size effects, we do not get the predicted decay rate } \lambda_L = 2\pi/\beta. \] And the OTOC only has a weak dependence on $\beta$ even in the strong coupling limit as shown in Fig. 9. Theoretically [11], in the large $N$ and strong coupling limit, $1 - \text{OTOC} \sim (\beta J/N) e^{(2\pi/\beta)t}$. Fig. 9 does not display a large change in the exponent, and the pre-factor difference is also small. It is clearly that of our small system sizes, $J$ is the most relevant energy scale that controlling the chaos.

**FIG. 8.** OTOC as a function of time at infinite temperature with different interaction strength $J = 1$ and $J = 2$. Here the total system size $N = 7$.

V. SYK MODEL FOR BOSONS

Now we consider a ‘cousin’ of the present model: SYK model for hardcore bosons. The bosonic case was also considered in the early work [1–4] but with a large number of bosons on each site. It was found that over most of the parameter regime the ground state had spin glass order. We will find evidence of similar behavior here.

The Hamiltonian will be quite similar as Eq. (1), except that because of the Bose statistics now the coefficients obey

\[ J_{ji;kl} = J_{ij;kl}, \quad J_{ij;lk} = J_{ij;kl}, \quad J_{kl;ij} = J_{ij;kl}^* \]  

(47)

Hardcore boson satisfies \([b_i, b_j] = 0\) for \(i \neq j\) and \(\{b_i, b_i^\dagger\} = 1\). Also to make particle-hole symmetry (40) hold, we only consider pair hoping between different sites, i.e. site indices \(i, j, k, l\) are all different, and we drop the normal order correction terms. The spin formalism in ED will be even simpler, as we do not need to attach a Jordan-Wigner string of \(\sigma_z\):

\[ b_i = \sigma_i^-, \quad b_i^\dagger = \sigma_i^+ \]  

(48)

We can define a similar Green’s function for bosons:

\[ G_B(t) = -i\theta(t)\langle\{b(t), b^\dagger(0)\}\rangle \]  

(49)
We identify the infinite time limit of $G_B$ as the Edward-Anderson order parameter $q_{EA}$, which can characterize long-time memory of spin-glass:

$$q_{EA} = \lim_{t \to \infty} G_B(t)$$

(50)

Then $q_{EA} \neq 0$ indicates that $G_B(\omega) \sim \delta(\omega)$. This is quite different from the fermionic case, where we have $G_F(z) \sim 1/\sqrt{z}$; this inverse square-root behavior also holds in the bosonic case without spin glass order [1]. Fig. 10 is our result from ED, with a comparison between $G_B$ with $G_F$. It is evident that the behavior of $G_B$ is qualitatively different from $G_F$, and so an inverse square-root behavior is ruled out. Instead, we can clearly see that, as system size gets larger, $G_B$’s peak value increases much faster than the $G_F$’s peak value. This supports the presence of spin glass order.

FIG. 10. Imaginary part of Green’s function for hardcore boson and fermion model. The peak near the center gets much higher in the boson model when system size gets larger. The inset figure is zoomed in near $\omega = 0$.

Unlike the fermionic case, $P^2 = 1$ for all $N$ in the bosonic model. We can apply similar symmetry argument as in Ref. [14]: for the half-filled sector (only in even $N$ cases), the level statistics obeys the Wigner-Dyson distribution of Gaussian orthogonal random matrix ensembles, while in other filling sectors, it obeys distribution of Gaussian unitary random matrix ensembles.

Our thermal entropy results for bosons are similar to the fermionic results: although the entropy eventually approaches 0 at zero temperature, there is still a trend of a larger low temperature entropy residue as the system size gets larger.
We have also computed the entanglement entropy for the ground state of the hardcore boson SYK model. It still satisfies volume law, and the entanglement entropy density is still quite close to ln 2. Finally results for the OTOC are qualitatively similar to the fermionic results.

VI. CONCLUSIONS

We have presented exact diagonalization results on the fermionic SYK model. The trends in the computed Green’s functions, high temperature expansion, entropy density, and entanglement entropy all support the conclusion that the large \( N \) limit approaches the compressible non-Fermi liquid state obtained in the earlier \( N = \infty \) analysis. Note that the entropy density approaches a non-zero value in the limit \( T \rightarrow 0 \) taken after the \( N \rightarrow \infty \), and so the ground state itself exhibits eigenstate thermalization. This conclusion is also supported by the volume-law behavior of the entanglement entropy. The original model of Ref. 1 was argued [4] to have an instability to spin glass order at temperatures exponentially small in \( \sqrt{N} \); the consonance between large \( N \) theory and our finite \( N \) numerics indicates that the model in (1) (with a random interaction with 4 indices [9]) does not have such an instability.

For the SYK model for hard-core bosons, our results for the single-particle Green’s function were very different, and indicate the presence of spin glass order. Similar quantum spin glass states were examined in random models of bosons in Refs. 3 and 4.
