What is the socially optimal level of liquidity in a retirement savings system? Liquid retirement savings are desirable because liquidity enables agents to respond to pre-retirement events that raise the marginal utility of consumption, like medical emergencies or income shocks. On the other hand, pre-retirement liquidity is undesirable when it leads to under-saving arising from, for example, planning mistakes or self-control problems.

This paper compares the liquidity that six developed economies have built into their employer-based defined contribution (DC) retirement savings systems. We find that all of them, with the sole exception of the United States, have made their DC systems overwhelmingly illiquid before age 55.

In the United States, employer-sponsored DC account balances can be moved to an individual retirement account (i.e., a “rollover” IRA) once the individual no longer works for the employer, which provides considerable scope for liquidation before the withdrawal-eligibility age of 59½. Pre-eligibility IRA withdrawals may be made for any reason by paying a 10 percent tax penalty, and certain classes of pre-eligibility IRA withdrawals are exempt from this penalty.

Liquidity generates significant pre-retirement “leakage” in the United States: for every $1 contributed to the DC accounts of savers under age 55 (not counting rollovers), $0.40 simultaneously flows out of the DC system (not counting

3 For example, no penalty is charged on withdrawals made for (i) permanent and total disability; (ii) unreimbursed medical expenses exceeding 10 percent of adjusted gross income; (iii) buying, building, or rebuilding a home if the withdrawal does not exceed $10,000 and the account holder has not owned a home in the past two years; (iv) higher education costs; (v) tax payments resulting from an IRS levy; (vi) health insurance premiums if unemployed for more than 12 weeks; (vii) a series of substantially equal periodic payments made over one’s life expectancy; (viii) distributions to an alternate payee under a qualified domestic relation order; or (ix) recovery from designated natural disasters.
loans or rollovers.\footnote{This amount of leakage may or may not be socially optimal, an issue that is beyond the scope of the current paper.} 

I. Analytic Framework

We focus on the five highest-GDP developed countries that have English as an official language: the United States, the United Kingdom, Canada, Australia, and Singapore.\footnote{We also analyze Germany, the largest developed economy with a substantial pool of DC savings that does not have English as an official language.} 

We analyze employer-based DC plans instead of defined benefit (DB) plans for three reasons. First, DC plans are gaining assets relative to DB plans in almost all countries around the world, including the six that we study. Second, DC plans already have more than half of retirement wealth in three of the countries that we study: Australia, Singapore, and the United States.\footnote{Third, in most circumstances, DC assets are at least as liquid as DB assets, so DC assets are the relevant margin for a household considering liquidating retirement wealth to augment pre-retirement consumption.} 

There are many ways to measure liquidity, including the actual quantity of liquidations or the marginal price of liquidations. We use the marginal price because statistics on actual liquidations are difficult to obtain. Even if such statistics were readily available, it is unclear how they should be compared across countries. For example, should liquidations be normalized by DC balances, retirement assets, total assets, or GDP? Also, from an economic perspective, the most natural object to study is the marginal price because it summarizes the incentives that consumers face.

Accordingly, we compute the marginal rate of transformation (MRT) between withdrawal-funded consumption at ages when the household is “pre-eligible” for withdrawals and withdrawal-funded consumption at ages when the household is “eligible” to make withdrawals (in all countries that we study, eligibility begins no earlier than 55 and no later than 63).\footnote{In Germany, access to vested occupational pension benefits is typically linked to eligibility for state-provided pension benefits. Benefits can only commence when the member provides a pension approval certificate (i.e., proof that she receives state-provided pension benefits). The early state retirement age for the long-term insured is currently 63.} 

\begin{equation}
MRT = \frac{1 - \tau(pre, y)}{1 - \tau(eligible, Y)} \times R^n.
\end{equation}

In this equation, \(\tau(pre, y)\) is the marginal tax rate (accounting for penalties and phase-outs of means-tested benefits) on a $1 withdrawal from the DC plan when (i) the household is young enough to be at a pre-eligible withdrawal age and (ii) the household’s employment income, \(y\), in the withdrawal year is less than or equal to the household’s permanent income, \(Y\). Likewise, \(\tau(eligible, Y)\) is the marginal tax rate on a $1 withdrawal from the DC plan when (i) the household is old enough to be eligible to make withdrawals and (ii) household earnings in the withdrawal year equal permanent income, \(Y\). Because we are studying a situation in which the household may have a liquidity need at a

\footnote{Singaporeans turning 55 after 2012 may only withdraw S$5,000 of their Central Provident Fund (CPF) balances plus amounts exceeding the Minimum Sum and Medisave Minimum Sum between age 55 and the drawdown age (currently 64). The remainder is paid out as an annuity beginning at the drawdown age.}

\footnote{In 2013, the Social Security trust fund contained $2.8 trillion, and other retirement plan assets totaled $23.0 trillion, summing to $25.8 trillion. DC plans (including the federal government’s Thrift Savings Plan and state and local DC plans) had assets of approximately $13.2 trillion, more than half of the $25.8 trillion total. Sources: Social Security Trust Fund, Investment Company Institute, Thrift Savings Plan, and authors’ calculations.}
pre-eligible age, we calculate how the $MRT$ varies as we change $y$. We assume permanent income is $Y = \text{US}\$60,000, which is approximately the median household income in each of the six countries. For simplicity, we set the gross real interest rate, $R$, to one (i.e., we set the net real interest rate to zero). Cross-country comparisons are not affected by this interest rate assumption.

We need to make additional demographic assumptions to pin down the household’s marginal tax rate. We assume the household is a one-earner married couple with no dependents that rents housing, takes the standard income tax deduction and is not disabled. In the pre-eligible withdrawal state, the earner is any age strictly under 55; in the eligible withdrawal state, the earner is at least 65 years old.

In some situations, withdrawals are completely prohibited in the pre-eligible state. We treat such a ban as a 100 percent marginal tax rate—i.e., $\tau(\text{pre, } y) = 1$. High values of the $MRT$ are associated with high levels of liquidity (early withdrawals are potentially encouraged), and low values of the $MRT$ are associated with low levels of liquidity (early withdrawals are discouraged or completely banned).

II. DC Liquidity Across Six Countries

We are now ready to describe the $MRT$ as a function of labor income during the pre-eligible withdrawal year, $y$, country by country. More detailed analysis and a description of our methodology are provided in the Appendix of Beshears et al. (2015b).

A. Germany, Singapore, and the United Kingdom

In Germany, Singapore, and the United Kingdom, early withdrawals are banned: $MRT = 0$ for all $y$\(^{12}\). Only disabled or terminally ill individuals may receive payments (an allowance that exists in all six countries). Singapore carves out some additional exceptions: a portion of DC balances may be used for medical expenses, a home purchase (which must be repaid with interest if the home is sold), and education (which must be repaid with interest in 12 years).\(^{14}\)

B. Canada and Australia

In Canada\(^{15}\) and Australia, the $MRT = 0$ under normal circumstances; but DC balances become liquid in the event of adverse transitory labor income shocks.

Canada (Ontario)—Employer-based DC plan balances cannot be accessed before the eligibility age unless a household’s expected income in the 12-month period following the application for withdrawal falls below US$32,428.\(^{12}\) Therefore, $MRT = 0$ at our hypothetical household’s normal

12 We do not consider the Supplementary Retirement Scheme in Singapore, a voluntary DC plan designed to complement the CPF. More details can be found in the Appendix of Beshears et al. (2015b).

13 In Germany, if the occupational pension plan covers disability, any payments during disability will be contingent on providing an official pension approval certificate from the social insurance system. If the employee is temporarily disabled, the payment of state-provided pension benefits will be discontinued and the employee will lose the pension approval certificate once s/he returns to work.

14 See Agarwal, Pan, and Qian (2014) for a discussion of spending that occurs in Singapore once participants can access part of their balance at age 55.

15 Our analysis for Canada considers Registered Pension Plans, which require employer contributions and are subject to both federal tax jurisdiction and federal or provincial pension legislation. Group Registered Retirement Savings Plans, on the other hand, do not require employer contributions and are not subject to pension legislation. Legally, these plans may allow for withdrawals at any age, but sponsoring employers can and typically do place restrictions on early access, at least until separation from employment. A more detailed analysis of these plans can be found in the Appendix of Beshears et al. (2015b).

16 There are some additional withdrawal provisions in these two countries, which are limited to a specific need (such as outstanding medical expenses, mortgage payments, etc.) or group (such as temporary residents permanently leaving Australia) and are explained in the Appendix of Beshears et al. (2015b).

17 We assume that the pre-eligible household accesses DC funds transferred to a “locked-in retirement account.” Withdrawals may be made from a locked-in account under the “low expected income” financial hardship provision if total expected income in the 12-month period following the application for withdrawal falls far enough below two-thirds of the YMPE to permit a withdrawal of at least C$500. The maximum eligible withdrawal amount is (50 percent $\times$ YMPE) - (75 percent $\times$ Expected Income during the Next 12 Months). Therefore, withdrawals of at least C$500 may be made when expected income falls to C$33,400, or about US$32,427 using the 2013 annual exchange rate: (50 percent $\times$ C$51,100) - (75 percent $\times$ C$33,400) = C$500. Due to the C$500 minimum withdrawal requirement, we calculate the $MRT$ in this case based
level of income: US$60,000. Once income in the pre-eligible withdrawal year falls below US$32,428, the \( \text{MRT} \) jumps from 0 to 1.11. The \( \text{MRT} \) increases with further declines in income, \( y \), because the marginal tax rate in the pre-eligible year falls while the marginal tax rate in the eligible year is held fixed. Means-tested benefit programs generate (local) nonmonotonicities in the marginal tax rate that feed through to the \( \text{MRT} \).

As income approaches zero, the \( \text{MRT} \) plateaus at a peak value of 1.50 (see Figure 1). Hence, the Canadian DC system has the intuitive property that, for a typical household, DC withdrawals are barred when income is near its normal level but are encouraged \( (\text{MRT} > 1) \) when income declines substantially.

**Australia**—In Australia, the \( \text{MRT} = 0 \) as long as the household remains employed, no matter how low income falls. However, if the household receives income support from the government for at least 26 weeks (e.g., unemployment benefits), the household becomes eligible for DC withdrawals\(^{18}\).\(^{19}\) Hence, Australia also has a rising \( \text{MRT} \) as income in the pre-eligible year declines if low income in the pre-eligible year is due to a long unemployment or underemployment spell and the household receives government benefits as a result (see Figure 2).

**C. United States**

In contrast, even at a normal level of income, the US DC system is liquid. Workers can roll over balances from a previous employer’s DC plan into an IRA and then liquidate those balances under any circumstances with a maximum tax penalty of 10 percent. For instance, if our hypothetical household lived in Texas, its \( \text{MRT} \) with pre-eligible income equal to permanent income would be

\[
\text{MRT} = \left( 1 - \tau_{\text{eligible}, Y} \right) / \left( 1 - \tau_{\text{pre}, Y} \right)
\]

As pre-eligible income falls below its normal level, the \( \text{MRT} \) tends to rise (as in Canada and Australia) due to falling marginal tax rates in the pre-eligible withdrawal year. As pre-eligible income approaches zero, the \( \text{MRT} \) eventually exceeds one (see Figure 3). Hence, like the Canadian and Australian systems, the US \( \text{MRT} \) increases as income falls transitorily, but the rise is much more muted in the United States: the \( \text{MRT} \) increases from 0 to 1.50 in Canada, from 0 to 1 in Australia, and from 0.88 to 1.06 in the United States.

**III. Conclusions**

The six countries that we study fall into three groups. In Germany, Singapore, and the United Kingdom, withdrawals from employer-based DC plans are essentially banned no matter what
kind of transitory income shock the household realizes.

By contrast, in Canada and Australia, liquidity in employer-based DC plans is sharply state-contingent. For a household that normally earns US$60,000, DC accounts are completely illiquid unless annual income falls substantially, at which point the DC assets may be accessed. Canadian workers who temporarily have very low income face strong incentives to withdraw their DC balances \((MRT = 1.50)\).

The United States stands alone in the high degree of liquidity in its DC system. Penalties for early withdrawals are relatively low, and early withdrawals are slightly subsidized as income falls transitorily.

This cross-country heterogeneity begs the question of why the United States has chosen a different path from its peers, a question we leave to future research.
