Comprehensive assessment of cellular responses to the RTS,S/AS01E vaccine is needed to understand potential correlates and ultimately mechanisms of protection against malaria disease. Cellular responses recognizing the RTS,S/AS01E-containing circumsporozoite protein (CSP) and Hepatitis B surface antigen (HBsAg) were assessed before and 1 month after primary vaccination by intracellular cytokine staining and 16-color flow cytometry in 105 RTS,S/AS01-vaccinated and 74 rabies-vaccinated participants (controls) in a pediatric phase III trial in Africa. RTS,S/AS01E-vaccinated children had significantly higher frequencies of CSP- and HBsAg-specific CD4+ T cells producing IL-2, TNF-α, and CD40L and HBsAg-specific CD4+ T producing IFN-γ and IL-17 than baseline and the control group. Vaccine-induced responses were identified in both central and effector memory (EM) compartments. EM CD4+ T cells expressing IL-4 and IL-21 were detected recognizing both vaccine antigens. Consistently higher response rates to both antigens in RTS,S/AS01E-vaccinated than comparator-vaccinated children were observed. RTS,S/AS01E induced polyfunctional CSP- and HBsAg-specific CD4+ T cells, with a greater degree of polyfunctionality in HBsAg responses. In conclusion, RTS,S/AS01E vaccine induces T cells of higher functional heterogeneity and polyfunctionality than previously characterized. Responses detected in memory CD4+ T cell compartments may provide correlates of RTS,S/AS01-induced immunity and duration of protection in future correlates of immunity studies.

Keywords: malaria, Plasmodium falciparum, vaccine, cellular immune responses, T cells, intracellular cytokine staining, flow cytometry
INTRODUCTION

A highly efficacious vaccine can substantially contribute to control and eventual elimination of malaria. This life-threatening disease caused an estimated 429,000 deaths in 2015 (1), mainly among sub-Saharan African children. In 2009–2014, the RTS,S/AS01E malaria vaccine was evaluated in a pediatric Phase III trial in Africa (2–4). Vaccine efficacy (VE) against clinical malaria over 1 year post-immunization was moderate (56%) in children enrolled at age 5–17 months and low (31%) in infants enrolled at age 6–12 weeks. Importantly, the protective effects waned quickly over time. To better understand why the RTS,S/AS01E vaccine induced only partial and short-lived protection against malaria, a thorough examination of the immune responses elicited, including different effector functions and memory phenotypes, using qualified or validated assays to ensure appropriate assay sensitivity and specificity to detect small frequencies of antigen-specific cells is needed.

RTS,S is a vaccine based on the circumsporozoite protein (CSP) of Plasmodium falciparum, targeting the sporozoite and liver stages of infection. This self-assembling virus-like particle consists of a recombinant protein containing part of CSP fused to the hepatitis B surface antigen (HBsAg) and it is coexpressed with HBsAg alone. In the Phase III trial, RTS,S was formulated with AS01E liposomal adjuvant containing monophosphoryl lipid A and QS21 and was designed to induce strong anti-CSP antibody and T helper (Th) 1 cell responses. Accordingly, in past clinical trials in endemic areas, RTS,S consistently induced high anti-CSP IgG titers (5–11) and moderate Th1 CD4+ T cell responses (5–10). IgG titers have been recently shown to correlate with vaccine-induced protection in secondary analysis of Phase III trial data (12, 13). However, IgG responses do not explain why RTS,S/AS01E VE is moderate or short-lived.

Regarding the cellular responses, CD4+ T cells expressing IL-2, TNF-α, and IFN-γ (and CD40L in naïve adults) have been detected by intracellular staining (ICS) or ELISpot (5–11, 14, 15) upon vaccination. In vaccinated naïve adults challenged with P. falciparum-infected mosquitoes, CSP-specific CD4+ T cells and IFN-γ measured by ELISpot were associated with protection (11, 14, 15). One study evaluating RTS,S/AS02D in African children less than 1 year old did not find any association with protection (5), whereas in another one with RTS,S/AS01E in children 5–17 months old observed CSP-specific TNF-α+ CD4+ T cell responses to be associated with a reduced risk of clinical malaria independently of anti-CSP IgG titers (8). Polymorphonuclear cells are restricted to a few immune variables have been studied. There has been no assessment of other cell effector functions, such as Th2 or follicular helper T cells (Th9), or memory phenotypes that may be induced by RTS,S/AS01E and could be correlated with antibody responses and involved in vaccine-induced protection. Interestingly, in the Phase III trial, we detected Th1 responses in supernatants of CSP-stimulated cells associated with protection in RTS,S/AS01E vaccinees, whereas a Th2 cytokine, IL-5, was associated with increased risk for malaria (16). To our knowledge, Th2 responses had only been examined in one previous study in humans, where IL-4 was found elevated in culture supernatants from RTS,S/AS02D-vaccinated infants (5). Lastly, memory T cell subsets have only been examined in a study with malaria-naïve adults who underwent a challenge with P. falciparum-infected mosquitoes after RTS,S vaccination. In that study, central memory T (Tcm) cells and effector memory T cells from RTS,S-vaccinated adults produced IL-2 after ex vivo CSP stimulation and frequencies were higher in protected vs. non-protected subjects (15).

Assessing the memory phenotype, the polyfunctionality degree and other relevant functions besides Th1 responses, such as Th2, Th17, cytotoxic, or immunoregulatory responses, may be key to identify functionally complex responses to RTS,S/AS01E and unravel its mode of action. In fact, complexity of the immune response to malaria and the partial and short-lived protection induced by RTS,S/AS01E stresses the need to expand the breadth of immunological profiling to Th2- and regulatory-type markers. This may be particularly relevant in infants in African settings, as they are exposed to prenatal and environmental factors that may modulate immune response to vaccines.

The aim of this study was to analyze RTS,S/AS01E cellular immunogenicity after primary vaccination using two qualified 16-color multiparametric ICS assays that allow the assessment of memory cell subsets and regulatory, cytotoxic, Th1, Th2, Th17, Th11 effector functions, most of them never assessed before, and to identify and establish a baseline of cell phenotypes and functional responses to be evaluated in studies of immune correlates of protection elicited by the vaccine. To this end, we analyzed the CSP- and HBsAg-specific cells ex vivo using previously cryopreserved peripheral blood mononuclear cells (PBMC) isolated from a subset of children aged 5–17 months at enrollment from Tanzania and Mozambique and following receipt of either the RTS,S/AS01E vaccine or a comparator rabies vaccine.

MATERIALS AND METHODS

Study Population and Study Design

We performed a study on a subset of 179 children aged 5–17 months from the RTS,S/AS01E Phase III trial (ClinicalTrials.gov NCT00866619), described elsewhere (4): 105 children received RTS,S/AS01E and 74 children received the rabies vaccine as a comparator at study months zero (M0), one, and two. PBMC were collected at M0 before vaccination and approximately 30 days after the third vaccination dose (M3). RTS,S/AS01E-vaccinated and rabies-vaccinated children were randomly selected for this
study among participants with no reported malaria episodes defined by observation of \textit{P. falciparum} parasites on blood smears, identified through passive case detection during 18 months of follow-up after third vaccination dose. Of note, PBMC samples from children who had malaria cases were reserved for future correlates analyses to test the selected markers identified in this study. Samples were collected in two different African centers: Manhiça Health Research Center, Fundação Manhiça (FM-CISM, Mozambique; 120 children), and Ifakara Health Institute and Bagamoyo Research and Training Centre (IHI-BRTC, Tanzania; 59 children). The two sites had low-medium malaria transmission intensity at the time of the study (2–4). Investigators conducted all assays blinded to vaccination status.

**Sample Collection**

Blood was collected in 5 ml sodium citrate (BD Vacutainer® CPT™) tubes. PBMCs were isolated by density gradient centrifugation, cryopreserved and shipped to the Fred Hutchinson Cancer Research Center where the PBMC were thawed and stained (see Methods in Supplementary Material).

**PBMC Stimulations**

Thawed PBMC were rested in a 37°C, 5% CO\textsubscript{2} incubator overnight. The resting step increases the sensitivity of the assay (data not shown), probably by decreasing the stress and activation of PBMC due to the thawing process and exposure to the toxic cryopreservation agent. PBMC were stimulated with peptide pools covering the HBsAg or the CSP antigen present in the RTS,S vaccine (Table S1 in Supplementary Material). Negative controls contained 0.5% DMSO, the diluent for peptide pools, and Staphylococcal enterotoxin B was used as positive control stimulation at 1 µg/ml. Cultures were incubated 6 h at 37°C, 5% CO\textsubscript{2}. This short incubation time increases the sensitivity and specificity of the assay to detect antigen-specific cells, avoiding non-specific and secondary immune responses. Further details are found in Supplementary Material.

**Intracellular Cytokine Staining**

Peripheral blood mononuclear cells were stained with one of two 16-color ICS panels that were designed for the study and that had previously undergone assay qualification with a formerly validated panel (17, 18). Cell staining was performed as described (17) (Supplementary Material). Antibody details can be found in Tables S2 and S3 in Supplementary Material. Data were acquired using a BD LSR II flow cytometer (BD Biosciences) directly from the plates using a high throughput sampler. We found some toxicity of HBsAg peptides, but since we could exclude dead cells, data were considered acceptable for analysis. We noted some spillover from CD154 to CXCR5 and therefore, T\textsubscript{H}1-like cells were excluded from the analysis. Flow cytometry analysis was performed using FlowJo software (Version 9.9 Tree Star). Gating strategies for both panels are shown in Figures S1 and S2 in Supplementary Material.

**Statistical Analysis**

The raw FCS files and manual gates were imported into the R environment (19) using the OpenCyto framework (20) and cell counts for the cell gates of interest were obtained for all stimulations and subjects.

For the analysis of the effect of vaccination on the frequencies of cells expressing the functional markers, a multivariate linear mixed effect model was fitted using logarithm-10 transformed cell frequencies (cells expressing the functional marker/total number of cells within each cell subset) as an outcome. These models are commonly used (21–24) and allow to model jointly the different cell stimulations that each subject sample underwent using random effects. The model included a random intercept for the subject effect nested within stimulation and a random slope for timepoint. In these models, observations generated by different subjects (biological replicates) are assumed to be independent. We included the following predictors in the regression models (as fixed effects): stimulation (CSP, DMSO, or HBsAg and DMSO, as appropriate), time of visit (pre- vs. post-vaccination), and vaccination status (RTS,S/AS01E vs. comparator vaccine), as well as all interactions between the three factors to allow variations of responses across subgroups of vaccinees and time. Linear combination of coefficients in these models allowed addressing specific study questions (details in Supplementary Material). Through these models, we estimated the % change in cell frequencies in RTS,S/AS01E vs. comparator vaccinees at each timepoint, the % change from M0 to M3 in each vaccine group, and the % change in RTS,S/AS01E vs. comparator vaccinees accounting for both timepoints. Statistical significance of comparisons was based on likelihood ratio tests. Antigen-specific responses were analyzed accounting for background, i.e., DMSO stimulation.

To define positivity of responses in each cell subset and subject, we identified the functional markers that were differentially expressed between the antigen (CSP or HBsAg) stimulations and their corresponding background (DMSO control stimulation) for each cell subset, subject, and at each timepoint. Thus, the proportion of cells expressing that marker was compared between the two stimulation conditions for each subject and timepoint. The statistical method used was mixture models for single-cell assays (MIMOSA) (25), using the default algorithm (Expectation–Maximization algorithm) and a false-discovery rate of 0.05%. This method was chosen because it has higher sensitivity and specificity than alternative methods such as Fisher’s exact test (25). A separate model for each functional marker, cell subset, and stimulation was fitted. Once we had defined the positivity or negativity for each functional marker, cell subset, subject, and timepoint, then the proportion of children with positive responses between vaccine groups at baseline or 1-month post-vaccination was compared using two-sided Fisher’s exact test.

Polypolfunctional responses (cell subsets that express multiple functional markers) were analyzed using combinatorial polyfunctionality analysis of antigen-specific T cell subsets (COMPASS) (26). COMPASS models all cell subsets expressing functional markers simultaneously and selects the subsets most likely to have a positive antigen-specific response. The antigen-specific response is quantified by the probability of having a positive response. COMPASS functionality and polyfunctionality scores, summarizing each subject’s polyfunctional profile, were compared.
between vaccine groups using Wilcoxon test. The functionality score is the estimated proportion of antigen-specific cell subsets detected among all possible ones, whereas the polyfunctionality score is similar but weighted by the degree of polyfunctionality.

In addition, COMPASS generates heatmaps that show the posterior probabilities for each modeled cell subset for each subject. CD107a marker was eliminated from MIMOSA and COMPASS analysis, because peptide pool stimulation was associated with a

related to TFH. Panel 2 (P2) included identification of memory cell subsets, and IL-21, a cytokine additionally had CD45RA and CCR7 markers that allowed the material; Tables S2 and S3 in supplementary material). P1 marker granzyme B (Figures S1 and S2 in supplementary material). The two panels had the same set of core markers, which allowed the exclusion of dead cells, monocytes (CD14), identification of CD4+ and CD8+ T cells (CD4, CD8 and CD3), NK and NK-T cells (CD56), the T17 cytokines IFN-γ, IL-2, and TNF-α, the T12 cytokine IL-4, the costimulatory molecule CD154 (CD40L), and the cytotoxic marker granzyme B (Figures S1 and S2 in supplementary material; Tables S2 and S3 in supplementary material). P1 additionally had CD45RA and CCR7 markers that allowed the identification of memory cell subsets, and IL-21, a cytokine related to TCM. Panel 2 (P2) included γδ TCR for the identification of γδ T cells and several functional markers: the regulatory cytokine IL-10, the T12 cytokine IL-13, the T17 cytokine IL-17, and cytotoxicity marker CD107a. The gating strategy is detailed in Figures S1 and S2 in supplementary material. The common set of core markers (lineage and functional markers) allowed the pooled analysis for these markers. Males and females were similarly represented in both study sites and vaccine groups, with a proportion of 59 and 56.8% females in the RTS,S/AS01E and comparator groups, respectively.

Frequencies of CSP- and HBsAg-Specific CD4+ T Cells Induced by RTS,S/AS01E

We compared frequencies of CSP- or HBsAg-specific T cells expressing functional markers in RTS,S- and rabies-vaccinated children, accounting for the pre-vaccination frequencies in a multivariate model. RTS,S/AS01E-vaccinated children had a statistically significant increase of CSP-specific CD4+ T cells expressing IL-2 (217% increase), TNF-α (72.3%), and CD154 (101.4%) from baseline to post-vaccination in contrast to the rabies vaccinees (Figure 1A, i). We observed larger increases over time of HBsAg-specific CD4+ T cells expressing IL-2 (732.2%), TNF-α (346%), and CD154 (268.3%) (Figure 1B, i) in RTS,S/AS01E than in rabies vaccinees.

Results

Study Population

We used two different multiparameter ICS panels to assess cellular immune responses specific to the RTS,S/AS01E vaccine antigens. PBMC from 55 RTS,S and 41 comparator vaccinees, and 50 RTS,S and 33 comparator vaccinees were stained with antibody panel 1 (P1) and panel 2 (P2), respectively. The two panels had the same set of core markers, which allowed the exclusion of dead cells, monocytes (CD14), identification of CD4+ and CD8+ T cells (CD4, CD8 and CD3), NK and NK-T cells (CD56), the T17 cytokines IFN-γ, IL-2, and TNF-α, the T12 cytokine IL-4, the costimulatory molecule CD154 (CD40L), and the cytotoxic marker granzyme B (Figures S1 and S2 in supplementary material; Tables S2 and S3 in supplementary material). P1 additionally had CD45RA and CCR7 markers that allowed the identification of memory cell subsets, and IL-21, a cytokine related to TCM. Panel 2 (P2) included γδ TCR for the identification of γδ T cells and several functional markers: the regulatory cytokine IL-10, the T12 cytokine IL-13, the T17 cytokine IL-17, and cytotoxicity marker CD107a. The gating strategy is detailed in Figures S1 and S2 in supplementary material. The common set of core markers (lineage and functional markers) allowed the pooled analysis for these markers. Males and females were similarly represented in both study sites and vaccine groups, with a proportion of 59 and 56.8% females in the RTS,S/AS01E and comparator groups, respectively.

Non-specific increase in CD107a compared to background, and response positivity could not be defined.

Statistical tests were considered significant at 0.05 α-level. Adjustments for multiple testing were done using Holm (27) and Benjamini–Hochberg (28) approaches. All analyses were conducted using R software. See supplementary material for detailed descriptions.

Figure 1 continued

CSP- and hepatitis B surface antigen (HBsAg)-specific CD4+ T cell responses induced by RTS,S/AS01E. CSP- (A) and HBsAg- (B) specific CD4+ T cells expressing the common functional markers of both intracellular cytokine staining panels. (i) Forest plot showing the overall effect of RTS,S/AS01E (R) vaccination from baseline (M0) to 1 month post-third immunization (M3) taking into account the M0-M3 changes in comparator (C) vaccinees. The % change between RTS,S/AS01E and comparator vaccinees taking into account M0-M3 changes and 95% confidence intervals shown were obtained with a multivariate linear mixed effect model. P values (P) were obtained through likelihood ratio test and were adjusted for multiple testing (P-Adj) through Holm’s approach. (ii) Box plots showing the frequencies of CD4+ T cells expressing the functional markers after background subtraction found to be statistically significant in (i). Boxplots illustrate the medians and the 25th and 75th quartiles, and whiskers display 1.5 times interquartile ranges, outliers are not shown to facilitate visualization of the differences between comparison groups. Differences between vaccine groups at M0 and at M3 and differences from M0 to M3 within each vaccine group were computed through a multivariate linear mixed effect model and P values obtained through likelihood ratio test and were adjusted for multiple testing through Holm approach. Only significant P values adjusted for multiple testing are shown. Sample size in (A), for markers detected by both staining panels N = 100 RTS,S/AS01E and 66 comparator at M0, 100 RTS,S/AS01E and 70 comparator at M3. For comparisons including M0 and M3, only subjects that had samples at both timepoints are included (N = 156 for markers detected by both panels, N = 83 for markers detected by panel 1, N = 73 for markers detected by panel 2). Sample size in (B) N = 62 RTS,S/AS01E and 36 comparator at M0, 67 RTS,S/AS01E and 50 comparator at M3. For IL-17 (detected by panel 2) N = 30 RTS,S/AS01E and 18 comparator at M0, 37 RTS,S/AS01E and 27 comparator at M3. For comparisons including M0 and M3, only subjects that had samples at both timepoints are included (N = 71 for markers detected by both panels, N = 35 for markers detected by panel 1, N = 36 for markers detected by panel 2).
FIGURE 2 | Continued
detected. Interestingly, RTS,S/AS01E vaccination also increased CD107a (\(\gamma\delta\) T, CD8+, T cells) or on other functional markers (Tables S5 and S6 in Supplementary Material).

Non-Specific CD4+ T Cell and CD8+ T Cell Responses Induced by RTS,S/AS01E Vaccination

Analysis of frequencies of cell subsets expressing functional markers in the background (DMSO, serving as the unstimulated control) revealed non-specific responses (i.e., not specific for CSP or HBsAg) upon RTS,S/AS01E vaccination (Figure 3). Accounting for baseline and responses in comparator vaccinees, RTS,S/AS01E vaccination increased the frequencies of CD4+ T cells producing IL-2 or TNF-\(\alpha\) or CD154, IL-4, and CD107a (Figure 3A, i). In comparator vaccinees, a decrease in these two subsets from baseline to post-vaccination was detected. Interestingly, RTS,S/AS01E vaccination also increased the frequencies of CD4+ T cells producing IL-4 and CD107a (Figure 3B, i).

Since we detected an effect of RTS,S/AS01E vaccination in the background, we looked at the \textit{ex vivo} antigen stimulations when not accounting for background. RTS,S/AS01E-vaccinated children had CD4+ T cells and CD8+ T cells expressing IL-4 and CD107a, as was observed for the background alone and, thus, likely reflecting non-specific responses (Figure S3 in Supplementary Material). Additionally, RTS,S/AS01E vaccination increased the frequencies of CD4+ T cells expressing IL-13 and CD8+ T cells expressing CD154 and IL-2 or TNF-\(\alpha\) or CD154 following CSP stimulation when not taking background into account (Figure S3 in Supplementary Material). These additional responses in RTS,S/AS01E-vaccinated children were no longer significant when taking into account the background and likely reflect a non-specific effect of RTS,S/AS01E vaccination.

Higher Proportion of Positive CD4+ T Cell Responses Defined by MIMOSA in RTS,S/AS01E than Comparators

To assess the vaccine specificity of the antigen-specific T cell responses detected and the rate of responders to the RTS,S/AS01E vaccine (participants whose T-cells responded to stimulation), we determined the positivity of the responses for each subject comparing the frequencies of T cells expressing a functional marker in the antigen-stimulated and unstimulated control conditions for each participant using the MIMOSA statistical method. If a response is truly vaccine specific, one would expect to detect it after vaccination but not at baseline or in the comparator vaccinees. We found a significantly higher proportion of IL-2+, TNF-\(\alpha\)+, and CD154+ CD4+ T cell positive CSP-specific responses in RTS,S/AS01E than in comparator vaccinees post-vaccination (Table 1). Response rates for these markers ranged from 24 to 30% in RTS,S/AS01E vaccinees; whereas for comparator vaccinees, there were none or very few responses (Table 1). Similarly, CSP-specific positive responses were absent or very low at baseline, supporting the specificity of the definition of positivity (Table S7 in Supplementary Material).

For HBsAg, we additionally detected more IFN-\(\gamma\)+ and IL-17+ CD4+ T cell positive responses in RTS,S/AS01E than comparator vaccinees at post-vaccination. Rates of HBsAg responders ranged from 26.7 to 76.1% in RTS,S/AS01E vaccinees (Table 1). However, a proportion of comparator vaccinees at post-vaccination and all vaccinees at M0 were also positive (Table 1; Table S7 in Supplementary Material), likely due to the fact that these children received the hepatitis B vaccine during the Expanded Program of Immunization (EPI) before the study. Most of the CSP responders were also HBsAg responders (Figure S4 in Supplementary Material).

When looking at CD4+ T_{eff} and CD4+ T_{EM} cell subsets, we found a significantly higher proportion of CSP responders in RTS,S/AS01E than in comparator vaccinees for IL-2, TNF-\(\alpha\), and CD154 (Table 2). Regarding HBsAg responses, RTS,S/AS01E vaccinees had higher rates of IL-2 and CD154 responses in CD4+ T_{eff} cells and IFN-\(\gamma\), IL-2, TNF-\(\alpha\), CD154 and IL-21 responses in CD4+ T_{EM} than comparator vaccinees. Very few positive responses to CSP and HBsAg were detected in comparator vaccinees or at baseline (Table 2; Table S8 in Supplementary Material). Almost no positive responses were found in the other cell subsets analyzed (CD4+ T_{TD}, CD4+ T_{N}, NK, NK-T like, \(\gamma\delta\) T, CD8+ T cells, and memory CD8+ T cell subsets), and no significant differences were detected between vaccination groups for any of the two vaccine antigens (Tables S9–S11 in Supplementary Material).
CSP- and HBsAg-Specific Polyfunctional CD4+ T Cell Responses Induced by RTS,S/AS01E

When analyzing the pooled data for the functional markers included in both panels, RTS,S/AS01 vaccinees had significantly higher functionality and polyfunctionality scores for CSP- and HBsAg-specific CD4+ T cells than comparator vaccinees (Figures 4A,B). Heatmaps of posterior probabilities of responses showed CSP-specific CD4+ T cell responses among subsets coexpressing three markers (IL-2, TNF-α, and CD154), and two markers (TNF-α and CD154; IL-2 and TNF-α) in RTS,S/
we also detected CD154 + identified additional highly polyfunctional CD4 functional makers included in each antibody panel separately, we

Figure 4A

AS01E vaccinees, whereas almost no responses were detected in comparator vaccinees or at baseline (Figure 4A, ii). For HBsAg responses, more CD4+ T cell subsets with positive responses and with higher degree of polyfunctionality were detected in RTS,S/AS01E vaccinees (Figure 4B, ii). Besides the same triple- and double-positive CD4+ T cell responses recognizing CSP antigen, we also detected CD154+ IL-2+ TNF-α+ IFN-γ+ CD4+ T cells and CD154+ IL-2+ TNF-α+ IL4+ CD4+ T cells. By contrast, comparator vaccinees or all vaccinees at baseline had none or weak responses to previous malaria exposure or hepatitis B vaccination. Therefore, RTS,S/AS01E induced polyfunctional CD4+ T cells to both vaccine antigens, with a higher degree of polyfunctionality for HBsAg that included T_{H2} and T_{FH} functions by RTS,S/AS01E. No polyfunctional responses were detected in CD8+ T cells for either vaccine antigen.

**DISCUSSION**

We provide a detailed characterization of the ex vivo antigen-specific T cell response induced by RTS,S/AS01E vaccination in a pediatric Phase III trial (2–4). In addition to previously described IL-2- and TNF-α-expressing CD4+ T cell responses (5–10), we have identified for the first time in a pediatric field trial T_{H2} effector functions and IL-21 in RTS,S vaccinees, attributed the responses to the central memory (CM) and effector memory (EM) compartments, and observed polyfunctional CD4+ T cell

*aGranzyme B was included in the analysis, but not shown because it is constitutively expressed independently of cell stimulation and activation.

*bData from markers detected by both staining panels, P1 and P2, are combined.

*cRaw P, original P-value computed based on two-sided Fisher's exact test.

dAdj P, P values adjusted for multiple testing through Holm's approach.
responses, which may be a key feature of a protective response. Although this analysis was limited to vaccine recipients who did not become infected with \( P. falciparum \), this study has identified key immune responses that can be examined in a larger case-control study within this trial.

RTS,S/AS01E vaccination induced distinct antigen-specific CD4+ T cell populations in a subset of children: CSP-specific IL-2, TNF-\( \alpha \), and CD154 CD4+ T cell responses and HBsAg-specific IFN-\( \gamma \), IL-2, TNF-\( \alpha \), CD154, and IL-17 CD4+ T cell responses. Frequencies of cytokine-positive CD4+ T cells were consistent with the frequencies of IL-2 and TNF-\( \alpha \) CSP-specific responses reported previously in RTS,S Phase II trials in endemic areas (5–10). Although no clear associations of TNF-\( \alpha \) and IL-2 responses with protection were found in past field studies, they could contribute in RTS,S-induced protection (8, 9). TNF-\( \alpha \) is an effector cytokine that may mediate mechanisms of \( P. falciparum \) pre-erythrocytic protection (29–31) and IL-2 induces proliferation of T cells and amplifies effector functions. CD4+ T cells producing IL-2 may contribute to the memory pool of CD4+ T cells with effector functions since they can be maintained during long periods of time and can develop into IFN-\( \gamma \)-producing T cells following subsequent stimulation (32). Of note, rates of IL-2 CSP responders (23–40% depending on the CD4+ T cell subset) were similar to the estimated VE in the Phase III trial (50% after a year of follow-up or 28% till study end) (4). IL-2 expression can also induce NK activation and secretion of IFN-\( \gamma \) (10, 33, 34), a key effector cytokine involved in malaria protection (35). Contrary to previous findings, we did not detect IFN-\( \gamma \) expression in CD4+ T cells or NK cells ex vivo following CSP stimulation (5, 7, 8, 10, 14). This is probably due to the short stimulation time in our study compared to longer times in whole blood assays from previous studies, which allowed bystander activation of CD4+ T cells and NK cells through IL-2 (10). Remarkably, we detected CD40L expression in antigen-specific CD4+ T cells, in contrast to previous field studies (6, 7).

Importantly, CD4+ T cell responses were detected in CM and EM compartments. Memory phenotypes are relevant to define high-quality and long-lasting responses, for instance, the higher proliferative potential of CM cells has been associated with protection from infection (32, 36–38). CD4+ TEM responses could be associated with the short protection observed in the trial. IL2+, CD154+, and TNF-\( \alpha \) CD4+ TEM cells were detected, whereas CD4+ TEM cells had additional effector functions, in accordance with the different cytokine profiles associated with these memory T cell subsets (32, 39, 40).

### TABLE 2 | Comparison of proportion of positive responses to CSP and hepatitis B surface antigen (HBsAg) in memory CD4+ T cell subsets between RTS,S/AS01E and comparator vaccinees 1-month post-third vaccination.

*bAdj \( P \), \( P \)-values adjusted for multiple testing through Benjamini–Hochberg approach.
and studies reporting CD4+ \text{T}_{\text{EM}} \text{ cells as the main producers of effector cytokines (32, 40). Higher frequencies of CD4+ \text{T}_{\text{EM}} \text{ cells expressing IL-4, and IL-21 for both vaccine antigens, and IFN-γ for HBSAg, were detected in RTS,S/AS01E-vaccinated children compared to baseline frequencies or comparator vaccinees.} \text{T}_{\text{H}12} (IL-4) \text{ and } \text{T}_{\text{FH}} (IL-21) \text{ effector functions together with CD40L could provide help to B cells for humoral responses and may correlate with antibody responses (41–44). No responses were detected in CD4+ \text{T}_{\text{TD}} \text{ cells, a cell subset with high IFN-γ effector function, with no long-term memory potential and fated for death (32).} \text{RTS,S/AS01E vaccination induced polyfunctional CSP- and HBSAg-specific CD4+ T cells. This finding is particularly important since multifunctional T cells have been associated with higher}
quality responses and risk (26) or protection from infections (45, 46). Most CSP and HBsAg positive responses were found in the triple functional marker CD4^+ T cell subset coexpressing IL-2, TNF-α, and CD154, although we also observed responses in a 4-function subset coexpressing IL-13. For HBsAg, we also found numerous responses in CD4^+ T cells subsets simultaneously producing four functional markers: IL-2, TNF-α, CD154 plus IL-21 or IFN-γ or IL-4, reflecting T_{Th1}, T_{H1}1 and T_{H1}2 distinct differentiation of these effector cell subsets.

Overall, HBsAg-specific responses were of higher magnitude, effector breadth and polyfunctionality than CSP-specific responses, suggesting a higher quality of response probably due to a booster effect since children should have been previously vaccinated with hepatitis B, or a higher immunogenicity of HBsAg compared to CSP due to the higher proportion of HBsAg than CSP in RTS,S (4:1).

RTS,S/AS01E may have a non-specific effect since higher background CD4^+ T cell and CD8^+ T cell responses were detected after vaccination compared with baseline. Since these responses included IL-4 and CD107a, it could be indicating a bias to a T_{H2} status and higher cytolytic potential of T cells in RTS,S/AS01E-vaccinated children. There is increasing evidence of non-specific effect of vaccines (47, 48), but a non-specific effect of RTS,S/AS01E may still have an impact on the response against *P. falciparum* infection. The significance of these responses may be worth noting in the context of the future correlates analyses. This finding of a non-specific effect highlights the importance of correcting for the background (by subtracting background) in order to assess antigen-specific effects.

In this study, we only included children without experiencing a documented malaria episode during the 18 months of follow-up, therefore, the clinical relevance of our findings will be assessed in future correlates studies. The exclusion of malaria cases is unlikely to bias results and affect study conclusions since malaria transmission intensity was low at that time in Manhiça and Bagamoyo and lack of malaria is not likely to be due solely to vaccine-induced protection, but also to lack of exposure to the mosquito-bearing parasite. Another potential limitation of our study relates to the toxicity of HBsAg peptide concentration used. Although this could impact cellular responsiveness, we did exclude dead and dying cells in the analysis, and it is likely that any impact would affect both vaccine groups.

The breadth of functions, patterns, and variability of responses to CSP, together with memory phenotypes of responding cell subsets described in our study, reflects a complex response to the RTS,S/AS01 vaccine. These responses, together with anti-CSP IgG data, may provide insights into the lack of protection in a substantial proportion of vaccinees, and may be key in providing correlates for VE and duration of protection.

ETHICS STATEMENT

Approval for the study protocol was obtained from the Ethical Committee of the Hospital Clinic in Barcelona (CEIC, Spain), the National Health and Bioethics Committee (CNBS, Mozambique), the Ethikkommission Beider Basel (EKBB, Switzerland), the National Institutional Review Board (NIMR, Tanzania), the Ifakara Health Institute IRB (IHIIRB, Tanzania), and the PATH’s Research Ethics Committee (REC, USA). Written informed consent was obtained from parents or guardians of participating children in accordance with the Declaration of Helsinki.

AUTHOR CONTRIBUTIONS

Substantial contributions to the conception or design of the work: GM, SR, CDa, CDo, and MJM. Acquisition of samples/data: GM, AN, MM, CJ, TR, JC, CDa, and CDo. Supervision analysis of samples: SR, KC. Analysis of data: GM, AA, JH, JA, DM, and CV. Data management: HS. Project management and coordination: ND-P and NW. Interpretation of data for the work and drafting the manuscript: GM, SR, CDo. Revising it critically for important intellectual content; final approval of the version to be published; and agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved: GM, SR, AA, AN, MM, KC, CJ, TR, JC, JH, HS, ND-P, NW, DM, JA, CV, CDa, CDo, MJM.

ACKNOWLEDGMENTS

We wish to thank all the participants of the study and their families. We thank the MAL055 clinical team, the field and laboratory personnel from the CISM, ISGlobal, and IHI-Bagamoyo research and training center, in particular Laura Puyol, Bendita Zavale, Lázaro Quimice, Nelito Ernesto José, Anneth Tumbo, and Helder Bulo, Carole Amroune, and Claudia Hernández for their administrative and management support. We are very grateful to the Fred Hutch research technologists, in particular, Terry Stewart, Paul Newling, and Kevin Hawkins for their work performing the PBMC stimulations, ICS assays and FlowJo gating. Thanks also to Carol Marty and David Chambliss for their logistic laboratory support. We are also grateful to the members of the MAL067 Vaccine Immunology Workgroup and its Working Groups (Statistical and Cellular). We would like to thank Marc Lievens for his help in the selection of samples. We also thank GSK Vaccines and PATH Malaria Vaccine Initiative (MVI) for their support in the conduct of the MAL067 Study. ISGlobal is a member of the CERCA Programme, Generalitat de Catalunya.

FUNDING

Supported in part by the PATH Malaria Vaccine Initiative (MVI), and grants from the National Institutes of Health (NIH)—National Institute of Allergy and Infectious Diseases (NIAID), grant number R01AI095789; the HIV Vaccine Trials Network Laboratory Center (HVTN, National Institute of Allergy and Infectious Diseases), grant number U1AI068618; the Human Immunology Project Consortium (HIPC, National Institute of Allergy and Infectious Diseases), grant number P30 AI027757; the Instituto de Salud Carlos III, grant number PS11/00423; and
the Agència de Gestió d’Ajuts Universitaris i de Recerca AGAUR, grant number 2014SGR991. CD was recipient of a Ramon y Cajal Contract from the Ministerio de Economía y Competitividad (RYC-2008-02631). GM was recipient of a Sara Borrell – ISCIII fellowship (CD010/00156).
