ABSTRACT

Introduction As many as 250 million children under the age of 5 may not be reaching their full developmental potential partly due to poor nutrition during pregnancy and the first 2 years of life. Micronutrients, including vitamin B\textsubscript{12}, are important for the development of brain structure and function; however, the timing, duration and severity of deficiencies may alter the impact on functional development outcomes. Consequently, to fully explore the effect of vitamin B\textsubscript{12} on cognitive function, it is crucial to measure neurodevelopment at different ages, in different populations and with vitamin B\textsubscript{12} supplementation at different times during the critical periods of neurodevelopment.

Methods and analysis In this project, we follow up children from four recently completed randomised placebo-controlled trials of oral vitamin B\textsubscript{12} supplementation, two in India and two in Tanzania, to explore the long-term effects on neurodevelopmental outcomes and growth. All the included trials provided at least two recommended dietary allowances of oral vitamin B\textsubscript{12} daily for at least 6 months. Vitamin B\textsubscript{12} was supplemented either during pregnancy, early infancy or early childhood. Primary outcomes are neurodevelopmental status, cognitive function and growth later in childhood. We apply validated and culturally appropriate instruments to identify relevant developmental outcomes. All statistical analyses will be done according to intention-to-treat principles. The project provides an excellent opportunity to examine the effect of vitamin B\textsubscript{12} supplementation during different periods of the critical first 1000 days and measure the outcomes later in childhood.

Ethics and dissemination The study has received ethical approvals from all relevant authorities in Norway, USA, Tanzania and India and complies fully with ethical principles for medical research. Results will be presented at national and international research and policy meetings and published in peer-reviewed scientific journals, preferably open access.

Protocol

Strengths and limitations of this study

- The current project takes advantage of recently completed randomised placebo-controlled trials to study long-term effects of oral vitamin B\textsubscript{12} supplementation on neurodevelopmental outcomes and growth in children in Tanzania and India.
- The project provides an excellent opportunity to examine the effect of vitamin B\textsubscript{12} supplementation during different periods of the critical first 1000 days and measure the outcomes later in childhood.
- The studies were not designed to follow the children up beyond the time of supplementation, which may lead to a somewhat high rate of loss to follow-up.
- The effect measures may be difficult to standardise across the different studies.

INTRODUCTION

New estimates based on proxy measures of stunting and poverty indicate that as many as 250 million children under the age of 5 from low-income and middle-income countries (LMICs) are at risk of not fulfilling their developmental potential partly because of poor nutrition during pregnancy and the first 2 years of life. Malnutrition and micronutrient deficiencies represent a major challenge to child health in many LMICs and are
associated with suboptimal cognitive function and poor growth.\textsuperscript{2} Many children in South Asia and Africa suffer from deficiencies of several nutrients including vitamin B\textsubscript{12}.\textsuperscript{3-7}

Why vitamin B\textsubscript{12} may be important for the developing brain

Vitamin B\textsubscript{12} plays a key role in normal brain development and function and is required for the folate-dependent enzyme, methionine synthase, which is necessary for the synthesis of methionine from homocysteine.\textsuperscript{8} Methionine in its activated form, S-adenosylmethionine, is the major methyl group donor used in human methylation reactions, including methylation of DNA and RNA. Deficient methylation reactions in the central nervous system can impair the methylation of myelin basic protein in the central as well as peripheral nervous system.\textsuperscript{9} The production of myelin is a key component of brain development from gestation, throughout childhood and well into middle age.\textsuperscript{10} The myelination of the brain is of importance for multiple brain systems and is highly related to neurodevelopment and subsequent cognitive functioning.\textsuperscript{11} Vitamin B\textsubscript{12} also serves as a cofactor in numerous catalytic reactions in the human body, which are required for neurotransmitter synthesis and functioning. Vitamin B\textsubscript{12} deficiency may cause pernicious anaemia with similar effects on cognitive development and functioning as anaemia caused by iron deficiency.\textsuperscript{12} Vitamin B\textsubscript{12} deficiency can also result in neuropathy through degeneration of nerve fibres and irreversible brain damage.\textsuperscript{13} However, although subtle vitamin B\textsubscript{12} deficiency is very common, the degree to which it has significant consequences for neurodevelopment and cognitive function is not established.\textsuperscript{14 15}

Vitamin B\textsubscript{12} and neurodevelopment

There is ample evidence that vitamin B\textsubscript{12} is important for cognitive development.\textsuperscript{11} In observational studies among adults and elderly, low levels of vitamin B\textsubscript{12} are associated with cognitive decline and dementia.\textsuperscript{16} Although there are fewer observational studies in children, the association between vitamin B\textsubscript{12} status and cognitive functioning has also been documented from early infancy to adolescence. Neonatal severe vitamin B\textsubscript{12} deficiency causes failure to thrive and possible irreversible neurological manifestations.\textsuperscript{12 17} A study in the Netherlands showed that infants fed on a macrobiotic diet, which is low in vitamin B\textsubscript{12}, had delayed gross motor, speech and language development compared with infants on an omnivore diet.\textsuperscript{18} In adolescence, these same children who were fed a macrobiotic diet for the first six years of life had poorer performance on cognitive tests, independent of their current vitamin B\textsubscript{12} status, compared with adolescents who were fed on an omnivorous diet.\textsuperscript{19} In a study from Nepal, we were able to demonstrate associations between early vitamin B\textsubscript{12} status and cognitive functioning 5 years later.\textsuperscript{20} These long-term associations remained strong, even after adjusting for several potential confounders. There is also evidence for the significance of vitamin B\textsubscript{12} to the developing brain in a few clinical trials. In a randomised controlled trial (RCT) Indian children aged 6–30 months were administered placebo or approximately twice the recommended daily allowances of vitamin B\textsubscript{12} and/or folic acid for 6 months. Children provided with vitamin B\textsubscript{12} and folic acid scored higher on a neurodevelopment assessment compared with the placebo group.\textsuperscript{21} The effects were most prominent in stunted children or children less than 2 years of age. A favourable effect of vitamin B\textsubscript{12} was also demonstrated on motor development in two RCTs involving Norwegian infants with developmental regressions and signs of vitamin B\textsubscript{12} deficiency 1 and 6 months following a 400 µg injection of vitamin B\textsubscript{12}.\textsuperscript{22 23}

Knowledge gaps

There is a need to clarify to what extent improving vitamin B\textsubscript{12} status impacts developmental outcomes in children in LMICs. It is also important to identify populations in which such interventions can be beneficial and at what age vitamin B\textsubscript{12} administration is most effective.\textsuperscript{11} Most studies in this field have used only motor function tests or general neurodevelopment assessments,\textsuperscript{24 25} while less is known on the effect of vitamin B\textsubscript{12} on specific cognitive functions such as executive functions, attention and sensorimotor and visuospatial abilities.\textsuperscript{26} The functions and areas under development are most sensitive to negative influences and will provide the most specific outcomes in assessments.\textsuperscript{25 26} Consequently, to fully understand findings in developmental assessments, we must consider the developmental timing of an exposure, in this case, vitamin B\textsubscript{12} supplementation (or lack thereof), as well as the timing of the assessment.\textsuperscript{25} Measuring neurodevelopment at different ages, in different populations and the effect of exposure at different times during the critical periods of neurodevelopment is needed to understand the role of vitamin B\textsubscript{12} in cognition.

Research on the impact of vitamin B\textsubscript{12} on the neurophysiological outcomes in children is scarce. Event-related potential (ERP) are non-invasive, reliable measures of neurophysiological brain function\textsuperscript{27} that provide direct measure of underlying neural activity of higher mental processes. Behavioural assessments may sometimes not be sensitive enough to detect these small changes in brain functions\textsuperscript{28} and these neurophysiological processes may be important correlates of the cognitive abilities and give new insight into the nutritional impact on the developing brain.\textsuperscript{29}

STUDY OBJECTIVES

The aim of the current study, the Vitabeginning project, is to determine the long-term effects of vitamin B\textsubscript{12} supplementation given during the first 1000 days of life on neurodevelopmental outcomes and growth.

General objective

► To provide evidence for the role of vitamin \( B_{12} \) supplementation in pregnancy or early childhood on neurodevelopment in vulnerable children in LMICs.

Specific objectives and objectives of the separate studies

► In North Indian children aged 6 to 30 months at enrolment, measure to what extent 6 months’ administration of vitamin \( B_{12} \) (1.8 µg) with or without folic acid (150 µg) improves neurodevelopment and cognitive function 5 years after the end of supplementation. Age range at follow-up is 7–9 years.

► In South Indian children, measure to what extent administration of daily vitamin \( B_{12} \) (50 µg) in combination with iron and folic acid from 14 weeks’ gestational age through 6 weeks postpartum improves neurodevelopment, cognition and neurophysiological function in childhood. Age range at follow-up is 5–6.5 years.

► In Tanzanian children, measure to what extent administration of vitamin \( B_{12} \) (50 µg) given with other vitamins from 11 to 17 weeks’ gestational age until delivery improves neurodevelopment and cognitive function up to school age. Age range at follow-up is 11–15 years.

► In Tanzanian children, measure to what extent administration of vitamin \( B_{12} \) (1 mg) given with other vitamins from week 6 to 18 months of age improves neurodevelopment and cognitive function up to school age. Age range at follow-up is 7–10 years.

► To estimate the effect of vitamin \( B_{12} \) administration on certain domains of neurodevelopment using pooled data from all of the above studies.

METHODS AND ANALYSIS

Study design and interventions

This study is a follow-up of four recently completed double-blind randomised placebo-controlled trials conducted in lower socioeconomic, semiurban and urban populations in Delhi (India), Bangalore (India) and Dar es Salaam (Tanzania) in 2001–2011. All trials provided at least two recommended dietary allowances (RDA) of vitamin \( B_{12} \) daily (2×2.6 µg for adults and 9 µg for small children) for at least 6 months, with no vitamin \( B_{12} \) supplementation in the placebo groups. The two studies that enrolled pregnant women provided the highest dose of vitamin \( B_{12} \) (50 µg daily, which is approximately 20 times the RDA). An overview of the original trials and the follow-ups is presented in table 1.
In Bangalore, South India, HIV-negative pregnant women recruited before or at 14 weeks gestational age were randomised to receive a daily dose of oral vitamin B₁₂ (50 µg) or a placebo through 6 weeks postpartum. The primary objective was to determine the effect of vitamin B₁₂ supplementation in improving maternal vitamin B₁₂ status. Enrolment was completed in September 2010, and the last enrolled infant was born in August 2011. Oral vitamin B₁₂ supplementation of women throughout pregnancy and early lactation, in combination with standard prenatal care with routine supplementation of iron and folate, significantly increased the vitamin B₁₂ status.
of women and their offspring. Neurodevelopment was measured at 9 and 30 months. In this follow-up study, we will measure the effect of maternal vitamin B12 supplementation on neurodevelopment and cognitive function several times 5–6.5 years after supplementation and on neurophysiological outcomes using ERP.

In Delhi, North India, children 6–30 months of age were randomised to receive daily (1) vitamin B12, (2) vitamin B12 and folate, (3) folate or (4) placebo for 6 months. The supplementation included vitamin B12 (1.8 µg) and/or folate (150 µg) and with half doses for children <12 months. The primary objective was to measure the effect of these interventions on the incidence of diarrhoea and pneumonia. Neurodevelopment was a predefined secondary outcome and was measured in a subsample of 422 children. In total, 1000 children were enrolled between January 2010 and September 2011. Vitamin B12 and folic acid-supplemented children scored significantly higher on neurodevelopment scores at the age of 12–36 months, compared with those who received placebo. In this follow-up study, we will measure to what extent early supplementation of folic acid and/or vitamin B12 improves neurodevelopment and cognitive function 5–6 years after supplementation. The study is powered to measure the effect of vitamin B12, folic acid and the two vitamins combined on neurodevelopmental outcomes. The follow-up study will also measure to what extent vitamin D status in early life is associated with neurodevelopmental scores in early school years.

In Dar es Salaam, Tanzania, infants 6–10 weeks of age born to HIV-negative mothers were randomised to receive daily (1) zinc, (2) multivitamins, (3) zinc + multivitamin or (4) placebo. Multivitamins included vitamin B12 1 mg, B1 0.5 mg, B2 0.6 mg, B6 0.6 mg, niacin 4 mg, folic acid 130 µg, vitamin C 60 mg and vitamin E 8 mg and was provided alongside zinc 5 mg. Doses were doubled after 6 months.

Children were followed for 18 months (ie, until age 19.5 months). The primary objective was to measure the incidence of diarrhoea and respiratory tract infections. Enrolment was completed in December 2009, and follow-up ended in May 2011. Neurodevelopmental outcomes were assessed in a subset of children at 15 months. Daily zinc supplementation lowered the burden of diarrhoea and respiratory tract infections. No added benefit was seen from the provision of multivitamins.

In another trial in Dar es Salaam, Tanzania on micro-nutrients and adverse pregnancy outcomes, HIV-negative pregnant women at 12–27 weeks gestational age were randomised to receive daily oral supplementation of multivitamins including vitamin B12 or placebo. Multivitamins included vitamin B12 50 µg, vitamin B1 20 mg, vitamin B2 20 mg, vitamin B6 125 mg, niacin 100 mg, vitamin C 500 mg, vitamin E 30 mg and folic acid 0.8 mg. All women received prenatal iron and folate supplementation. The primary objective was to measure the effect of vitamin supplementation on fetal loss, low birth weight and severe preterm birth. Enrolment was completed in July 2004,

![Figure 1](image.png)
and the last enrolled infant was born in February 2005. Multivitamin supplementation reduced the incidence of low birth weight and small for gestational age births but had no significant effects on prematurity or fetal death. The two studies from Tanzania are well suited for follow-up studies on potential impact of micronutrient supplementation on child health and neurodevelopmental outcomes in older children.

**Outcomes**

Neurodevelopment, cognitive function and linear growth will be key outcomes in the different studies.

**Neurodevelopment**

Neurodevelopmental status in young children has been assessed by the comprehensive assessment tool Bayley Scales of Infant and Toddler Development third edition and the easily administered screening tool Ages and Stages Questionnaire third edition in the original studies.

In the follow-up, each site use their own unique collections of tests and questionnaires (table 2). General intellectual functioning is assessed by a modified Kaufmann ABC II (Bangalore and Dar es Salaam), the Wechsler Preschool and Primary Scale of Intelligence–III (Bangalore) or the Wechsler Intelligence Scale for Children VI, Indian version (Delhi). These are complemented by tests on specific cognitive functions by subtests from the developmental neuropsychological test battery A Developmental NEuroPSYchological Assessment, version 2 (NEPSY-II) including attention and executive functioning, language, social perception, sensorimotor and visuospatial processing (Delhi) and adaptive functioning by the Vineland Social Maturity Scale (Bangalore). Mental health and behaviour problems are measured by the parent-reported screening instrument Strengths and Difficulties Questionnaire and executive functions by the parent-reported questionnaire Behaviour Rating Inventory of Executive Function (all sites). Finally, in one study (Bangalore), we measure neurophysiological functions using event-related potentials as this may yield additional information on the effects of nutritional deficiencies on brain function. In the present study, we propose to use two well-characterised ERPs, P-300 and Mis-match Negrativity that are known to reflect higher cognitive functions of attention and memory (see table 2 for details on the assessments at each site).

**Anthropometry**

Weight and height are measured using standard methods. In Delhi, height, weight and skin fold thickness were measured in children, using Seca scales (height/weight) and Holtain Calipers. In Bangalore, weights of mothers and children were recorded using a digital balance (Salter’s 9016; Tonbridge) to the nearest 100 g, and the heights were measured using a stadiometer to the nearest 0.1 cm.

**Sample size calculation**

The data for our most relevant tests are expected to be normally distributed. We have decided that a standardised effect size of 0.35 SD is the minimally clinically relevant effect for the main psychometric tests. If the smallest group in any of our comparisons includes at least 130 children in each arm, and assuming a two-sided alpha error of 0.05 we will have 81%, 89% and 98% power to detect differences for effect sizes of 0.35, 0.4 and 0.6, respectively. As a result, all of the described studies have sufficient power to detect important differences between vitamin B12 status or placebo recipients apart from each other. Statistical powers according to standardised mean effect sizes of .35, 0.4 and 0.6 and total sample sizes are depicted in figure 1. This graph was generated using the ‘power two means’ command in STATA V.13; it assumes equal group sizes and equal variances and a significance level of 0.05.

**Data collection**

Data collection for the primary and secondary outcomes are synchronised and selected to capture the same domains of development using different tools. Assessment tools for cognitive functions such as general abilities, achievement, verbal, visual spatial and sensorimotor skills, memory, executive functioning, general behaviour and social perception and maturity are dependent on the child’s age. We have carefully selected well-validated and developmentally sensitive instruments to ensure detection of the relevant predictors according to age and research questions. Instruments are adapted to ensure psychometric qualities, as well as cultural and linguistic appropriateness of the test at each site. Clinically useful tests will be prioritised to improve sustainability of test material and knowledge of developmental assessment at the specific sites. Assessments are administered by trained psychologists in the Indian sites and by trained healthcare workers in the Tanzania site. A group of experienced scientists with expertise in developmental, neuropsychological and neurophysiological assessments are responsible for the training and standardisation in the different sites.

**Analysis plan**

Several domains will be measured and compared between the study groups within each of the studies. In these analyses, we will initially use the Student’s t-test for the crude analyses and multiple linear regression models to adjust for potential baseline differences and when measuring effect modification.

Each of the studies has several outcomes as we will compare both linear and ponderal growth, in addition to all the above-mentioned neurodevelopmental measures between the study groups. Thus, there will be several comparisons from each study, and negative and positive
Effects will be reported to avoid focusing on spurious positive findings.

For each of the planned publications, we will make a detailed plan of analysis before commencing the analysis. In these plans, we will include sections on how to deal with multiple comparisons and whether post hoc adjustments will be done. In addition to these standard per-protocol analysis, we will consider instrumental variable analysis in an attempt to estimate the true effect of vitamin $B_{12}$ had it been given to all participants in the scheduled doses and intervals. The random allocation will be the instrument in these analyses. For per-protocol analysis, participants who received less than 50% of the projected doses during the period of intervention will not be included in the analyses, well acknowledging that the ensuing effect estimates may not only be biased but will certainly represent an effect higher than what can be achieved even in our well-resourced study setting.

For our subgroup analyses, we will include interaction terms to measure whether or not the subgrouping variable significantly modifies the effect of the exposure of interest. All of our analyses will initially be done according to intent to treat.

We will not be able to retain the complete number of children from these studies. We will compare the features of the population that is included in this analysis with the population that we failed to re-enrol into the study. We will also detect risk factors for poor neurodevelopment in multiple linear or binomial regression models. We will include socioeconomic and seasonal factors and dietary intake as exposures in the analyses. A significance level of 0.05 will be used.

ETHICS AND DISSEMINATION

Ethical and safety considerations

The exposures under investigation in this study were included in the original trials. Informed written parental consent will be taken from one or both parents of participating children prior to enrolment in the follow-up study and assent will be obtained from children older than 7 years in the Delhi site. Parents unable to read or write will be encouraged to bring along a literate relative or neighbour as an impartial witness.

Relevance and benefit to society

The current project takes advantage of four recently completed randomised placebo-controlled trials to study the long-term effects of vitamin $B_{12}$ supplementation on neurodevelopmental outcomes and growth in children in low- and middle-income countries. When measuring the effect of vitamin $B_{12}$ on growth and development, long-term follow-up is important: vitamin $B_{12}$ can be stored for years in the body, and the effect of an increased intake for a relatively short period such as 6 months may accordingly last much longer. Furthermore, for many of the neurodevelopmental outcomes, it might not be possible to estimate the effect of early life exposures until later in childhood because of limitations in the assessment tools. Thus, to follow children for a long time, as in this project, is important to fully understand the role of vitamin $B_{12}$ for brain development and growth.

In most studies, follow-up for several years is not possible, so the results from our studies will be of great importance. Since none of the RCTs originally were designed for such long-term follow-up, there is risk that loss to follow-up can bias our effect estimates. There is, however, no reason to believe that the loss to follow-up rate will be different according to randomised regimen in any of the described studies. The risk of confounding of the main exposures (Vitamin $B_{12}$ supplementation) is small because of the RCT design and the large number of randomization units. Substantial imbalances of potential confounding factors across study groups are unlikely.

If positive effects of supplementation are observed, this may constitute important contributions to improve childhood nutrition in many LMICs. However, several factors may have profound impact on long-term neurodevelopment outcomes and growth and potentially dilute the effect of optimising vitamin $B_{12}$ status in early life. Our findings, however, must be interpreted in light of the results from other RCTs that are measuring the effect of vitamin $B_{12}$ supplementation on growth and development. If anything, our findings will guide our next step in understanding the role of vitamin $B_{12}$ nutrition on child growth and development: Should there be additional follow-ups in the ongoing studies or will the results from our studies discourage further studies on vitamin $B_{12}$ and child health?

If none, or very few, of our several outcomes respond to vitamin $B_{12}$ supplementation, alone or when given in combination with several other micronutrients, then poor vitamin $B_{12}$ status is likely not an important contributor to impaired neurodevelopment. Thus, we believe that a negative result of our studies is also of substantial public health importance.

Millions of children across the world grow up malnourished lacking essential nutrients, with high burden of infectious diseases and where parents may not have the resources to provide an optimal environment for nurturing care. Acting in early childhood, these factors may result in poorer chances for later success in school and work. The results from the RCTs can lead to dietary recommendations that can improve learning and academic achievements, which again can lift individuals from the vicious cycle of poverty and malnutrition. Programme designed to prevent or treat micronutrient deficiencies can be targeted towards specific recommendations. Any further evidence for the long-term effect of dietary supplements has potentially high impact and may provide sustainable improvements in health and equity.

The suggested studies are geared towards rapid dissemination of results into national and international child
health promotion programme. We will actively use the potential influence of the international collaborators to ensure that our results reach the relevant health authorities.

Planned publications
Study results will be presented at national and international research and policy meetings, and published in peer-reviewed scientific journals, preferably open access. We will also discuss alternative strategies to inform the public. We will publish scientific papers as a consortium, specifically directed towards developmental and neuropsychological assessment methodology and site-specific publications. We expect each of the sites to generate approximately five publications in high-ranked international peer-reviewed journals.

Contributors
TAS, IK, CPD and WF took the initiative for the study. TAS, IK, CPD, WF, BAW, SK, KM, ST, MH, NB and ES were involved in developing the design and the study protocol. ST, SK and KM were responsible for setting up the study conduct in each site, with support from AMD, ST, TK, AK and SB. The statistical approach to the study was drafted by CRS, MH, TAS and WF. MH, IK, ES, DCB, and SK were responsible for the cognitive assessments. All authors approved the final version of the protocol. BAW, IK and TAS drafted the current manuscript. All authors have reviewed and accepted the final version of the manuscript.

Funding
The Vitabeginning study was funded by the Norwegian Research Council Grant number 234495. The original trial in Bangladesh was funded by the Indian Council of Medical Research (grant 5/7/192/06-RHNI) and Eunice Kennedy Shriver National Institute of Child Health and Human Development (grant R03 HD054123). The study in Delhi was funded by the Thrasher Research Fund (grant no. 02827) and the Research Council of Norway (grant 172226). The trials in Tanzania were funded by National Institute of Child Health and Human Development (NICHD R01 37701) and the Eunice Kennedy Shriver NIH grant (R01 HD048969-01). CPD is supported by NIH (grants K24DK104676 and P30 DK040561).

Competing interests
None declared.

Patient consent
Detail has been removed from this/these case description/s to ensure anonymity. The editors and reviewers have seen the detailed information available and are satisfied that the information backs up the case the authors are making.

Ethics approval
Ethical Review Board in Norway (2014/1359, 2015/640), in addition to approvals from partners in USA, Tanzania and India.

Provenance and peer review
Not commissioned; externally peer reviewed.
