Lobar pneumonia treated by Musgrave Park physicians

John Hedley-Whyte, Debra R Milamed

Accepted 5 January 2009

SUMMARY

In the decade 1935-45 the treatment of lobar pneumonia in the developed and warring world underwent a series of evolutions—anti-sera, specific anti-sera, refinement of sulphapyridine drugs, sulphapyridine and anti-sera, the introduction of penicillin for bacteriology, then ophthalmology, and then for penicillin-sensitive bacterial infections such as lobar pneumonia with its many Cooper types of Streptococcus pneumoniae. Penicillin for civilian use was essentially banned in World War II, a ban that early in 1941 two Musgrave Park physicians tried to circumvent. Strict secrecy on the details of penicillin production was enforced. The treatment option chosen by the Musgrave Park physicians in 1941, and the non-availability of penicillin led to sequelae affecting the post-Belfast careers of both patient and physicians.

KEY WORDS: Sera, Sulpha, Penicillin

INTRODUCTION

At the start of his 1944 Campbell Oration1, the newly knighted Alexander Fleming (Figure 1) mentioned his 40-year collaboration and mentorship with Ulsterman Sir Almroth Wright. He thanked his friend, housemate and long-time collaborator Victor Douglas Allison, Queen's MB, later DSc. Allison had been the JC White Lecturer in Bacteriology, Queen's University6. After working with Wright and Fleming, as a Beit Memorial Research Fellow, he became a Senior Consulting Pathologist to Belfast City Hospital and the Northern Ireland Hospitals7. Fleming also recalled his World War I service with the Professor of Medicine 1921-50 at Queen's, WWD Thomson, knighted in 19503,6,8.

When they returned to take the Belfast-Larne train, the Flemings discovered they were missing his lantern slides and lecture notes1. The Ulster authorities and British security knew that since 1941 all details of antibiotic production by the World War II Allies had been strictly classified secret. The train was delayed; the Larne to Stranraer ferry's escort rescheduled. The notes were found, vetted, and restored to Sir Alexander. The Flemings were then allowed on their way back to London and Allison's Highgate house where Allison kept a pied à terre for visits from Cardiff where he was stationed. The Flemings had been bombed out of their Chelsea home2.

WORLD WAR I: FLEMING, THOMSON AND WRIGHT

Captain Alexander Fleming had worked under Colonel Sir Almroth Wright's command from 1915 to 1918 at Boulogne2,7. Captain WWD Thomson and Captain N Keith of Canada, later of the Mayo Clinic, were junior officers in this Unit devoted to the study of Allied War Wounds and their infection. Harvard's US 5th General Hospital was also stationed in Boulogne with Professor Harvey Cushing as Commanding Officer, and Professor Roger Lee as Chief of Medicine. Both were friends of Wright's group, and Cushing collaborated in Wright's work on war wounds9,10. In 1919 Harvey Cushing was awarded an honorary MD by Queen's, Belfast10. Cushing was in 1926-27 to train Hugh Cairns11, later Nuffield Professor of Surgery at Oxford, at the Peter Bent Brigham Hospital, Boston. Cairns, in 1942, both abridged and amplified Cushing's experience12. Lee was to train Professor Maxwell Finland at Harvard13-15. Fleming, Keith and Thomson were frequent golfing companions at Wimereux where their golfing feats incurred Wright's displeasure, but did not strain their friendship. Sir Almroth Wright maintained his high regard for the trio. Fleming, when out of sight behind a dune, had dropped a "somewhat self-important Colonel's ball" so as to fake a hole in one, and demand the customary sequelae of drinks on the Colonel16.

In his Campbell Oration, Fleming mentioned neither the secret work on penicillin in the United States since his visit to New York in 1939, nor the efforts of two Musgrave Park 31st General Hospital doctors to obtain penicillin in March 194117. One of the pair, Max Rosenheim, later President of the Royal College of Physicians and enabled with an FRS, had also in March 1941 asked the Wright-Fleming group for advice on Type XIV anti-pneumococcal serum7.

WORLD WAR II BELFAST

In March 1941, under optimal circumstances, the preferred treatment regimen for lobar pneumonia was to determine as expeditiously as possible the Cooper type of infecting pneumococcus: to take a blood sample for culture was advised18. Before these results were obtained, polyclonal pneumococcal antiserum could be given intravenously with caution19. This done, a loading dose of sulphonpyridine, then called M and B 693, was given, generally by mouth18,19. Sulphathiazine was thought to have less toxicity, but was new and expensive (Table I). The patient's hydration, nutrition and mental attitude needed to be bolstered during the course of the
Both Musgrave Park physicians Benjamin Rycroft and Max Rosenheim knew penicillin was extremely effective against pneumococcal (now called streptococci pneumoniae) infections, and that penicillin did not appear to cause nausea, vomiting, heart arrhythmias and diarrhoea, as did M and B 693. Both Rosenheim and Rycroft knew that penicillin was being produced at Oxford and in New York at Columbia University, “in a manner that took over many rooms”.

The Allies had by June 1944 achieved their objective of ensuring that their Forces had enough penicillin to treat expected casualties in the Normandy landing and breakout. Fleming's Penicillin notatum (NRRL 1249), isolated 1929, was a producer only in surface culture. NRRL 1249 did not produce when submerged. After searching all over the world for Penicillin notatum-chrysogenum which could produce when submerged, the best strain proved to be from a cantaloupe in a Peoria, Illinois fruit market (NRRL 1951). Mutation sequence began on the best substrain, 1951-B25, Demerec of the Carnegie Institution of Washington’s Cold Spring Harbor Laboratory, developed a superior X-ray mutant 1951-B25 X1612 which was commercially produced, but was superseded by strain Q-176, which was an ultraviolet-produced mutant derived from X-1612 by the University of Wisconsin. Fleming’s mold NRRL 1249 produced 2-4 Oxford Units per ml, 1951-B25. Q-176 produced 750 times Fleming’s mold. The United States efforts to ramp up the production of penicillin during World War II was given funding priority equal to the Manhattan project to develop uranium and plutonium bombs. Secrecy was strictly observed. Sareen Sally McElroy was a trained nurse, the twin daughter of a County Mayo farmer. The Flemings were very happily married from 23rd December 1915, when Alexander was on leave from his duties in Boulogne with Ulstermen Sir Almroth Wright and Thomson until Sareen’s terminal illness and death on 29th October 1949.

What Rosenheim did not know was whether specific type XIV anti-pneumococcal serum was available. My father kept his copies of The Medical Annual in the library of our Dunmurry Lane home. The 1940 edition, which I inherited from him and still possess, has a section on “New Pharmaceutical

Preparations. The section on “Antipneumococcal Sera (Rabbit), Lederle, covers the ‘higher types’ of pneumococcal pneumonias for which horse sera have not previously been available.” Supplies of antisera are now available in 20,000 unit vials for all the 32 Cooper types except Types XV, XXV, XXVI, and XXX. These vials are manufactured by Lederle Laboratories Inc., New York, NY. Literature on application to the distributors CF Thackray Ltd, Park Street, Leeds. In March 1941, Type XIV was not available on demand in a timely manner from Lederle, New York, nor from the Leeds distributor. The reason that rabbits had supplanted horses was that production of the “higher types” of antipneumococcal serum killed about a third of the horses. This high equine mortality was not experienced in producing lower types I, II and III; in these “original” types equine production probably had higher profit margins. There were more patients for types I, II and III and greater production from the sensitised horses.

As a result of his telephoned investigations, Rosenberg discovered Squibb was about to release “Antipneumococcal Rabbit Serum Type XIV.” Type XIV lobar pneumonia was then relatively uncommon in the United Kingdom. One New York-based study reported type XIV pneumococcus as comprising 16.1 percent of lobar pneumonias in children, but only 2.6 percent in adults. Type XIV produced mortality rates as high as 14 percent in children and 23 percent in adults without bacteremia, and 28 percent in children and 69 percent in adults with bacteremia.

DISEASE COURSE

On a stormy dawn early in March 1941, I awoke in my bedroom at Windy Ridge, Dunmurry Lane with pain in my right side. I called my father who came in his dressing gown and that he would get Rycroft whom I already knew. I asked why I needed an eye doctor. “He kept the city of Bradford in order as a GP,” my father replied. Rycroft arrived about an...
hour later and took a venous blood sample and several throat swabs (Figure 2, Table II).

Later, a tubby, cheerful man appeared in civilian clothes and said to me and my nurse, “I am Max” (Figure 3). He told me that the next three to five days would be like climbing a mountain. I would probably get more breathless and the pain in my right chest was best put up with. He then listened to my chest and said “Angus and the eye doctor are right”. Max gave me an intravenous injection which he said had been made by Sir Almroth Wright and Professor Fleming and left, saying he would be back when he had checked up on the eye doctor. A few hours later Rycroft appeared with some pills he made me swallow (Figure 4). Rycroft said in future he would announce his arrival by playing on the piano in the room beneath my bedroom.

That evening I asked my father who Max was, to be told he was a Salopian Johnian. The nurse, who was from Sligo, said that Max was very nice. “Where was he from?” My father replied, “The Massachusetts General Hospital”. So I asked if he was an anaesthetist. “No, he was Belton Pollard Fellow with Albright and Bauer,” my father replied. Late the next day Max reappeared and said he had made a lot of people work including Angus and the eye doctor, so he was going to give me back some of my own medicine—so started my intravenous course of Type XIV antipneumococcal serum.

replied, “The Massachusetts General Hospital”. So I asked if he was an anaesthetist. “No, he was Belton Pollard Fellow with Albright and Bauer,” my father replied. Late the next day Max reappeared and said he had made a lot of people work including Angus and the eye doctor, so he was going to give me back some of my own medicine—so started my intravenous course of Type XIV antipneumococcal serum. I asked what Rycroft had been forced to do. “Argue with Oxford,” was the reply.

The next day but one, Rycroft changed his piano tune from “Smoke Gets in Your Eyes” to “The Blue Danube”. He came upstairs and said, “John, you are better or Max’ s army career is over before it begins”. “Yes, I am,” I replied. “Can I go and see my pony?” “Not yet.” Max reappeared somewhat later. He said he had called Whitby. I replied, “My ancestors there
are dead”. Max said he had also been talking with Wright’s people at Mary’s. They had reminded him how to do a Quellen reaction and a precipitin test to type the pneumococci\textsuperscript{13-37}. He said they had no spare penicillin. “Try Oxford and New York,” advised Sir Almroth. So he had given that job to Rycroft, “Because eye-doctors couldn’t get into trouble because of the Duke (Figure 5). Ophthalmologists know more about penicillin than anyone else”. “Good-bye,” said Max. “Go to a college on the Backs of the Cam”.

1941 UNITED STATES IN ULSTER

I never saw Max in uniform during his posting to Musgrave Park. When I asked for an explanation, I was told, “Because he was dealing with the Yanks.” The next month after my pneumonia, April 1941, was the time of the Belfast blitz. The still neutral US War Department issued RAINBOW-5, which detailed the deployment of 30,000 US troops in Ulster. On June 12, 1941, the construction contract for US bases and hospitals in Northern Ireland was signed\textsuperscript{41}. Rosenheim, with his recent Harvard experience advised on what Harvard’s Fifth General Hospital\textsuperscript{34} and other US Medical Services would require. He liaised with Professor WWD Thomson\textsuperscript{8} for WWD’s own experience at Boulogne of Harvard’s Fifth General Hospital in World War I.

THERAPEUTIC ALTERNATIVES

To determine the pneumococcal type from the samples obtained by Rycroft, Rosenheim used concurrent techniques described by Lionel Whitby, Pathologist to the Middlesex Hospital. “Type may be determined by an immediate direct method, by mouse inoculation or by agglutination of a culture”\textsuperscript{54}. In the direct method, a small fleck of fresh sputum is well mixed on a slide with a drop of the type I, II or III serum. “After the serum has penetrated into the sputum, a cover-slip is placed over the preparation and it is examined with the 1/6\textsuperscript{th} lens and x10 eyepiece. The capsule of an organism, when in contact with its own specific serum, becomes swollen and the organism itself loses its definition”\textsuperscript{54}.

“The white mouse is very susceptible to pneumococcal infection, and if inoculated intraperitoneally with a sample of pneumococcal sputum, not only are the mucus and the cellular elements liquefied, rendering the pneumococci free, but the cocci also multiply rapidly”\textsuperscript{54}. The peritoneal cavity of the mouse is aspirated after four hours and the direct method repeated. Under microscopic examination, the capsule of the diplococcus is swollen by its own specific serum. If no swelling occurs, as it did not in my case, the search continued with expensive specific serum for the remaining known, as of 1932-1941, twenty-nine types.

Rosenheim then used mouse inoculation as described by Whitby and obtained evidence of agglutination of a mouse heart blood sample. A suspension of the culture is tested for agglutination in dilutions varying from 1:1 to 1:20 with each of the type-specific sera. The tubes should be incubated in a water bath for one hour at 37°C. The peritoneal washings of an incubated mouse can also provide a suitable suspension for this test. Further confirmation that the infecting pneumococcus was type XIV was provided by the precipitin reaction using the polysaccharide hapten known as Specific Soluble Substance, or SSS from urine\textsuperscript{54}.

Fig 5. Sir Stewart Duke-Elder, GCVO, MD, DSc, FACS, FRCS, FRCP, FRS (1898-1978). Oil on canvas by Ruskin Spear, reproduced with the permission of Moorfields Eye Hospital and UCL Institute of Ophthalmology, solely for this Medical History. “The Duke” was Surgeon Oculist to Their Majesties Edward VIII, George VI, and Elizabeth II. Educated at St. Andrews and London Universities, Howe Lecturer, Harvard University, 1930, Craig Prize, Belfast, 1952. Brigadier General 1940-46, later Consulting Ophthalmic surgeon to the British Army, 1946-61. Married in 1928 Phyllis Mary Edgar, MB, BS (London), who helped her husband with his legendary texts\textsuperscript{58,59} including his Craig Prize Oration\textsuperscript{60}. Ruskin Spear also portrayed Lord Ashby, Vice Chancellor of Queen’s Belfast and Master of Clare.

Fig 6. Comparison between childhood death rates before and after the introduction of sulphanilamide and antibiotic chemotherapy. Figures were provided by the Association of the British Pharmaceutical Industry to Professor Ronald Hare\textsuperscript{41}. 
In 1939, an annotation in this journal on the treatment of pneumococcal infections stated that for a child of seven, an initial dose of M and B 693 of 1.5 0.5g tablets should be followed by 1 tablet every four hours. The Ulster Medical Journal continues, “It is of importance even with this brand of drug that every case should be typed.” “Physicians…may wish to supplement their treatment …with administration of specific serum.” In 1940 a study from Birmingham showed that the mortality in 1,685 successive patients, with lobar pneumonia admitted to the Dudley Road Hospital dropped from 20.5 percent in 1936 and 1937 to 5.3 percent after the introduction of M and B 693. In Birmingham, type I pneumococcus predominated 43%, type III 16%, type II 11%, type XIII 5%. The other types were “encountered only sporadically and types XIII, XIV, XXII, XXVI and XXX not at all.” In Los Angeles, California, in the five years from January 1934 through December 1938, type XIV lobar pneumonia represented only 1% of 1,469 consecutive cases of lobar pneumonia. Things were different in Harlem, NY, where type XIV had been shown to be a virulent pneumococcus “selecting by preference infants and young children, in whom the pneumonias are usually of long duration—it is especially prone to invade the blood and prove fatal” (Figure 6).

PERSONAL SEQUELAE

My parents complained of the paltry British Army pay. So I asked the cost of my treatment. The M & B 693 sulphapyridine cost £1 per day. My illness cost “a fiver”. The anti-sera were free samples. “The Germans invented a dye called prontosil, for which Professor Domagk was awarded the Nobel Prize in ’3922,65,66 (Figure 7). The French stole it and the English improved it so you got better and did not go pink or blue”33. I later asked what a Quellen test was and why Mary’s had to coach Max. “To discover you are Type XIV”. So I asked why I was Type XIV. “Because you probably kissed someone”. “I don’t kiss girls”. - John, you had better go to the Dragon School.”

Production figures derived from Lord Florey’s Antibiotics published in 1949 and US figures declassified in stages post-World War II. The 150-fold increase in US production from June 1943 to D-Day was largely due to irradiation procedures. War-time secrecy and patent protection inhibited and delayed US to British Empire information transfer. The University of Toronto delivered approximately 1,000 Oxford Mega Units to Canadian Armed Forces in May 1944.
My father wrote to the Dragon Preparatory School on Bardwell Road, just north of Oxford University. Father was told that they were full. So when my father next met his friend Hugh Cairns, Nuffield Professor of Surgery at Oxford, he claims he made him feel guilty for procrastinating on the release of penicillin for me. The excuse was they had “run out on a rose scratch case”. If I had been given the penicillin I would have been the third patient in the first Oxford series (Table III). Professor Cairns, as propitiation, said he would call on the Lynams (Hum and son Joc, co-Head-Masters), and there would be no trouble. I entered the Dragon as a boarder in September 1942 to learn that the most prominent of the Oxford Dons that founded the school in 1877 was a Mr George, who thereafter had his Dragons both male and female: all to be aged seven to thirteen. We Dragons aspired to “robust informality and relaxed vigour”.

Max Rosenheim left Belfast to become officer in charge, Medical Division, in various countries in the Middle East and North Africa, ending his Army service as a Brigadier General and consulting physician to the Allied Land Forces South East Asia. At one of our teas or Sunday lunches that the Cairns family gave me at their home around the corner from the Dragon School, I asked why Max had been sent so far away. Professor Cairns replied, “Because of your penicillin”. “But I didn’t get any, and anyhow Rycroft did the asking.” “Yes, but we all knew Max was behind it”. Professor Cairns then said “Did you know Rycroft had to swim for awhile on the way to North Africa? He was torpedoed and they had trouble picking him up”. He’s good at using penicillin.

Max Rosenheim left Belfast to become officer in charge, Medical Division, in various countries in the Middle East and North Africa, ending his Army service as a Brigadier General and consulting physician to the Allied Land Forces South East Asia.
Dr. Lionel Whitby is the subject of an October 2008 WHO Position Paper and is now endorsed against a moving target of invasive pneumococcal disease.

**POSTSCRIPT**

Memory, while obviously fallible, is said to be most reliably implanted at seven years of age. My recall has been aided by my father Angus’ notes on the course of my loban pneumonia, which are on pages 5, 6 and the inner cover of his copy of Oliver’s Medicine which had survived bombing in Rennes on June 17th, 1940. Memory was reinforced in later years by meeting with my physicians in Belfast, Cambridge, London and Boston and by parental and uxorial admonitions.

The authors have no conflict of interest.
