Deficiency of Phosphoinositide 3-Kinase Enhancer Protects Mice From Diet-Induced Obesity and Insulin Resistance

Chi Bun Chan,1 Xia Liu,1 Dae Young Jung,2,3 John Y. Jun,2 Hongbo R. Luo,4 Jason K. Kim,2,3 and Keqiang Ye1

OBJECTIVE—Phosphoinositide 3-kinase enhancer A (PIKE-A) is a proto-oncogene that promotes tumor growth and transformation by enhancing Akt activity. However, the physiological functions of PIKE-A in peripheral tissues are unknown. Here, we describe the effect of PIKE deletion in mice and explore the role of PIKE-A in obesity development.

RESEARCH DESIGN AND METHODS—Whole-body PIKE knockout mice were generated and subjected to high-fat–diet feeding for 20 weeks. The glucose tolerance, tissue-specific insulin sensitivity, adipocyte differentiation, and lipid oxidation status were determined. The molecular mechanism of PIKE in the insulin signaling pathway was also studied.

RESULTS—We show that PIKE-A regulates obesity development by modulating AMP-activated protein kinase (AMPK) phosphorylation. PIKE-A is important for insulin to suppress AMPK phosphorylation. The expression of PIKE-A is markedly increased in adipose tissue of obese mice, whereas depletion of PIKE-A inhibits adipocyte differentiation. PIKE knockout mice exhibit a phenotype of lipatrophy and are resistant to high-fat–diet–induced obesity, liver steatosis, and diabetes. PIKE knockout mice also have augmented lipid oxidation, which is accompanied by enhanced AMPK phosphorylation in both muscle and adipose tissue. Moreover, insulin sensitivity is improved in PIKE-A–deficient muscle and fat, thus protecting the animals from diet-induced diabetes.

CONCLUSIONS—Our results suggest that PIKE-A is implicated in obesity and associated diabetes development by negatively regulating AMPK activity. Diabetes 59:883–893, 2010

Obesity is a result of imbalanced energy intake and expenditure in which the accumulation of excessive fat causes disorders such as type 2 diabetes, atherosclerosis, and dyslipidemia (1). Because of its increasing prevalence in most of the world, obesity has become a major health problem (2). Although genetic linkage analysis has successfully mapped potential loci in human genome for adiposity development (3), identifying all genetic variants that contribute to differences in body weight is still one of the major goals to fully understand the mechanism of obesity progression. Recent studies using genome-wide linkage scan revealed human chromosome trait 12q14.1, where the phosphatidylinositol 3-kinase (PI 3-kinase) enhancer (PIKE) gene CENGT1 locates, has a strong correlation with serum lipid level and energy intake (4,5), suggesting PIKE may be a potential factor in regulating body weight.

PIKEs are a family of GTPases that directly interact with PI 3-kinase and Akt and enhance their kinase activities (6–8). The family contains three members: PIKE-L, PIKE-S, and PIKE-A, which is generated from alternative splicing of the CENGT1 gene. Whereas PIKE-S and -L are brain specific, PIKE-A is widely expressed, such that its mRNA could be detected in brain, heart, liver, muscle, spleen, thymus, and small intestine (9,10). The mode of action of PIKE is isoform specific in different cell types. PIKE-L couples to receptors such as netrin receptor (UNC5B) and metabotropic glutamate receptors I (mGluR-I) and links the activated receptor to PI 3-kinase pathway in neurons (11,12). PIKE-S localizes in nucleus and executes the protective effects of nerve growth factor by activating the nuclear PI 3-kinase cascade (8). PIKE-A, on the other hand, substantiates the kinase activity of Akt in glioblastomas and is involved in cancer invasion activity (6,13,14). However, the role of PIKE-A in peripheral tissues remains unknown.

In many cases, insulin resistance is the major associated pathologic condition of obesity. However, the molecular mechanism of this obesity-induced disorder remains ambiguous. It has been proposed that lipotoxicity is one of the candidates to explain the role of excess lipid storage in insulin resistance onset. Accumulation of excess cellular lipid changes the lipid metabolism, enhances oxidative stress, and disrupts endoplasmic reticulum homeostasis (15). Increasing cellular lipid oxidation by pharmacologic interventions in obese subjects thus represents a potential therapeutic regimen to mitigate their diabetic complications. In this regard, AMP-activated protein kinase (AMPK) is one of the targets. AMPK is the master sensor for energy status and is responsible for metabolic homeostasis (16).
Activation of AMPK in reducing hepatic glucocorticogenic gene expression and glucose production, increasing fatty acid oxidation, and enhancing glucose uptake. Therefore, AMPK activators such as AICAR and meftomin are effective agents in relieving the obesity-induced insulin resistance in both laboratory and clinical tests (17).

To examine the role of PIKE in obesity, we developed the whole-body PIKE knockout (PIKE(-/-)) mice with ablation of all PIKE isoforms. Here we report that PIKE-A is implicated in adipocyte differentiation and obesity development. PIKE knockout elicits lipoatrophy and increased insulin sensitivity by enhancing AMPK activity, leading to resistance against high-fat diet (HFD)-induced obesity and diabetes.

RESEARCH DESIGN AND METHODS

**Generation of knockout animals and genotyping.** Heterozygous PIKE(-/-) C57BL/6 mice with a targeted deletion of exons 3–6 of CNTG1 were generated under contract with Ozygene (Bentley DC, Australia). Genotyping was performed by PCR using genomic DNA isolated from the tail tip. PCR was performed using a combination of primers D (5’ACAGGATCTACGTGACATCATCTC-3’) and H (5’CAGGATCAAGAGCTTCAGTG-3’), A (5’CAGGATCAGTGGAAGCTT-3’), and C (5’CCAGAGCCTATCATGCTGAG-3’).

**Immunoprecipitation and Western blotting.** Tissue extracts were prepared by homogenizing the tissues in buffer as reported (18). Immunoprecipitation was performed as described (18). Antibodies used in the Western blot analysis were obtained from Santa Cruz Biotechnology (insulin receptor, Akt) and Cell Signaling Technology (anti-phospho-Thr(237) of AMPK, anti-phospho-Ser(79) of acetyl-CoA carboxylase [ACC], anti-AMPKα, and anti-ACC).

**Southern blot analysis.** Southern blot analysis using mouse tail genomic DNA was performed as reported (19).

**Analytic procedures.** All animal experiments were performed according to the care of experimental animal guidelines from Emory University. Twelve-week-old female mice were fed with chow or HFD (Research Diets) for 20 weeks. Blood glucose level was measured by ACCU-CHEK Advantage Blood Glucose Meter (F. Hoffmann-La Roche, Basel, Switzerland). Serum insulin was measured by ELISA (Crystal Chem). Serum triglyceride level was measured by Serum Triglyceride Determination Kit (Sigma-Aldrich). Serum tumor necrosis factor-α (TNF-α) was measured by ELISA (BD Biosciences). Glucose tolerance test (GTT) was performed on mice after peritoneal injection of d-glucose (2 g/kg body wt).

**In vivo insulin stimulation.** Animals (16 h fasting) were anesthetized by intraperitoneal administration of sodium pentobarbital (50 mg/kg body wt). Saline or 5 units human insulin (Eli Lilly) was injected through inferior vena cava. After 5 min, liver, hind limb muscles, and inguinal fat were removed and immediately frozen in liquid nitrogen.

**PI 3-kinase assay.** In vitro PI 3-kinase assay was performed using anti-p110α (Santa Cruz Biotechnology) as described previously (8).

**RT-PCR.** Total RNA from various tissues was prepared by Trizol Isolation Reagent (Invitrogen). First-strand cDNA from total RNA was synthesized using Superscript III reverse transcriptase (Invitrogen) and Oligo-dT15 as primer. Amplification of predopcyte factor 1 (Pre-F1), adipocyte protein 2 (aP2), preadipocyte factor 1 (Pref-1), adipocyte protein 2 (aP2), and preadipocyte factor 1 (Pref-1) as described previously (8).

**Fatty acid oxidation assay.** Fatty acid oxidation was measured by determining the production of 14C from [1-14C]-palmitate as reported (21). Hyperinsulinemic-euglycemic clamp and metabolic cage studies. Metabolic cage studies and in vivo glucose metabolisms including glucose infusion rate, glucose turnover rate, and glycogen synthesis were determined by hyperinsulinemic-euglycemic clamp as reported (22,23).

**Statistical analysis.** Results were considered significant when P < 0.05. Statistical analysis was performed using either Student t test, one-way ANOVA, or two-way ANOVA followed by Tukey multiple comparison test or Bonferroni post-tests using the computer program GraphPad Prism (GraphPad Software).

Detailed experimental procedures are in the supplementary methods (http://diabetes.diabetesjournals.org/cgi/content/full/db-09-1404/DC1).

**RESULTS**

**Generation of PIKE knockout mice.** As a pioneer study on the physiological role of PIKE in obesity development, we generated whole-body PIKE(-/-) mice with targeted disruption in the CNTG1 locus using the LoxP/Cre system. We first created a transgenic line with PIKE(exon1flox/+) allele by inserting two loxP sites into the introns flanking exons 3 and 6 (Fig. 1A). PIKE(exon1flox/+) mice were then bred with transgenic mice expressing Cre recombinase in all tissues. Deletion of exons 3–6 results in removal of GTPase domain and introduces a frameshift mutation that creates a new stop codon, producing truncated PIKE proteins for all isoforms. Heterozygous mating generated newborn pups at expected Mendelian frequency that appeared indistinguishable from the wild-type littermates, suggesting that PIKE was dispensable for embryonic development. Southern blot analysis showed exons 3–6 of the CNTG1 gene were effectively excised (Fig. 1B), which was further supported by PCR analysis (Fig. 1C). Immunoblotting analysis using antibody specific to the COOH-terminal of PIKE-A and RT-PCR confirmed the ablation of PIKE-A expression in various tissues (Fig. 1D and E). PIKE(-/-) mice are viable and fertile. However, a significant reduction of white adipose tissues (WATs) was detected in the PIKE(-/-) mice, whereas no noticeable difference was found in other peripheral tissues (Fig. 1E).

**PIKE(-/-) mice are resistant to diet-induced obesity.** When fed a chow diet, the body weight of female PIKE(-/-) mice was slightly, but significantly, lower at 8 weeks old compared with wild-type mice (17.29 ± 0.27 vs. 16.33 ± 0.29 g, P < 0.05, n = 7, Student t test). The difference was more prominent in mice fed with HFD (55% of calories derived from fat). After HFD feeding for 14 weeks, obesity developed in wild-type but not in PIKE(-/-) animals (Fig. 2A). Daily food intake of PIKE(-/-) mice fed a chow diet was normal, but the amount of food intake in PIKE(-/-) mice was substantially less than that in the control fed HFD (Fig. 2B). Increased body weight was associated with a drastic gain of inguinal WAT weight in wild-type but not in PIKE(-/-) mice (312% in wild-type vs. 46.5% in knockout) (Fig. 2C). The adipocytes in PIKE(-/-) mice were also smaller in both feeding conditions (Fig. 2D and E). Moreover, circulating leptin and TNF-α concentrations were lower in PIKE(-/-) mice (Fig. 2F and G). Expression of PIKE-A was greatly enhanced in the WAT and muscle of mice fed with HFD and the genetically obese (ob/ob) mice (Fig. 2H, first and fifth panels). In contrast, no noticeable alternation of hepatic PIKE expression was detected among all the tested groups (Fig. 2H, third panel), suggesting a tissue-specific function of PIKE-A in obesity development.

**PIKE is essential for adipocyte differentiation.** Under chow diet feeding conditions, expressions of mature adipocyte markers aP2 and the master regulators of adipocyte differentiation, PPARγ and C/EBPα (24,25), were reduced in PIKE(-/-) WAT (Fig. 3A). However, no significant difference was found in preadipocyte marker Pref-1 between wild-type and mutant. Comparable increment of
FIG. 1. Targeted disruption of PIKE. A: Schematic representation of mouse PIKE (top), the targeting vector (middle), and the targeted gene region (bottom). The locations of loxP sites were marked as solid triangles and of FRT sites, as solid bars. B: Southern blot analysis of progeny produced from heterozygote mating. Genomic DNA was isolated from mouse tail and was digested with NheI and probed with fragment A as indicated. The 8.5-kb band represents the wild-type allele and the 6-kb fragment corresponds to the knockout allele. C: PCR screening of mice from heterozygote mating. Genomic DNA isolated from wild-type (+/−H11545), heterozygous (+/−H11545), and knockout (−/−H11546) mice tail was used in PCR screening. The locations of primers used in the reactions were indicated in A. D: RT-PCR screening of PIKE expression in different tissues. Complementary DNA was synthesized from RNA extracted from various tissues as indicated. Primers D and H as shown in Awere used in PCR (upper panel). Expression of GAPDH was examined as the internal control (lower panel). E: Western blot analysis of PIKE-A. Proteins extracts of different tissues from wild-type (+/+), heterozygous (+/−), and knockout (−/−) mice (3 months old) were prepared, and the expression of PIKE-A was detected using specific antibody against the COOH-terminal of human PIKE-A (top panel). The amount of tubulin in each sample was examined to demonstrate equal loading (bottom panel). Representative result of three mice from each genotype was shown. F: Weight of heart, spleen, pancreas, kidney, and inguinal WAT in 3-month-old mice. The weight was normalized with the total body weight and was expressed as means ± SEM (n = 5). Significant reduction of WAT weight was observed in PIKE−/− mice (***P < 0.001, Student t test).
For 20 weeks (animals (8–9 months old) that have been fed with chow diet or HFD was measured in a 3-day period. Results were expressed as mean ± SEM (***P < 0.001 vs. the same genotype; b: P < 0.01). C: Weight of inguinal WAT from wild-type (+/+) and PIKE knockout (−/−) mice fed with chow or HFD was measured in a 3-day period. Results were expressed as mean ± SEM (***P < 0.001 vs. the same genotype; c: P < 0.001 vs. the same diet; one-way ANOVA). D: Pictures of hematoxylin-eosin (H&E) staining of inguinal WAT sections from wild-type (+/+) and PIKE-null (−/−) animals (8–9 months old) that have been fed with chow diet or HFD for 20 weeks. Representative results of three different mice from each genotype were shown. Scale bar represents 50 μm. E: Quantification of inguinal WAT cell area from wild-type (+/+) and PIKE-null (−/−) animals (8–9 months old) that have been fed with chow diet or HFD for 20 weeks. Results were expressed as mean ± SEM (***P < 0.001 vs. the same genotype; b: P < 0.01 vs. the same diet treatment; one-way ANOVA). F: Circulating leptin concentration of wild-type (+/+) and PIKE knockout (−/−) mice (8–9 months old) that have been fed with chow or HFD for 20 weeks. Results were expressed as mean ± SEM (n = 4; ***P < 0.001 vs. the same genotype; a: P < 0.05, b: P < 0.01 vs. the same diet treatment; one-way ANOVA). G: Circulating TNF-α concentration of wild-type (+/+) and PIKE knockout (−/−) mice (8–9 months old) that have been fed with chow or HFD for 20 weeks. Results were expressed as mean ± SEM (n = 4; ***P < 0.001 vs. the same genotype; a: P < 0.05, b: P < 0.01 vs. the same diet treatment; one-way ANOVA). H: Elevated PIKE-A expression in the WAT and muscle of diet-induced or genetically obese mice. RNA from WAT, liver, and muscle of Ob/Ob mice or normal mice (8–9 months old) that have been fed with chow diet or HFD was extracted and reverse transcribed. (A high-quality color representation of this figure is available in the online issue.)
PIKE is essential for adipocyte differentiation. A: Impaired adipose gene expression in PIKE-null WAT. RNA from ingunal WAT of wild-type (+/+) and knockout (−/−) mice (8–9 months old) that have been fed chow or HFD for 20 weeks was collected and used in RT-PCR. Expression of preadipocyte markers Pref-1, mature adipocyte marker aP2, transcription factors PPARγ and C/EBPα was normalized to GAPDH. Results were expressed as fold induction against the corresponding expression level in wild-type animals fed with chow diet (n = 3, *P < 0.05; **P < 0.01; ***P < 0.001, Student t test). B: Oil red O staining of MEFs isolated from wild-type (+/+) and knockout (−/−) mice before (day 0) and after (day 8) induced adipocyte differentiation. Scale bar represents 50 μm. Representative result of three independent experiments is shown. C: Quantitation of accumulated lipid in MEFs before (day 0) and after (day 8) isobutylmethylxathine-dexamethasone insulin (MDI) induction. Oil red O in the MEFs was extracted by isopropanol and measured in optical density 500 nm. D: Impaired adipose gene expression in PIKE-null MEFs. RNA from MEFs of wild-type (+/+) and knockout (−/−) mice before (day 0) and after (day 8) induced adipocyte differentiation. Expression of mature adipocyte marker aP2 and transcription factors PPARγ and C/EBPα was normalized to GAPDH. Results were expressed as fold induction against the corresponding expression level in day-0 wild-type MEFs (n = 3, **P < 0.01; ***P < 0.001, Student t test). (A high-quality digital representation of this figure is available in the online issue.)

PIKE-A is an Akt upstream effector, which binds Akt and enhances its kinase activity in glioblastomas (6,13). It is thus anticipated that PIKE−/− mice would display diabetic phenotypes as deletion of Akt2 in mice showed impaired glucose tolerance (28). To our surprise, blood glucose level is normal in PIKE−/− mice. Because Akt1−/− or Akt3−/− mice have no obvious defect in glucose homeostasis, the normoglycemic condition in PIKE−/− mice could be explained if PIKE-A associates selectively with Akt1 and Akt3 rather than Akt2. As predicted, PIKE-A preferentially bound both Akt1 and Akt3 (supplementary Fig. 2A), suggesting that only Akt1 and Akt3 activities may be altered in PIKE−/− tissues. Concurrent with this notion, the brain mass of PIKE−/− mice was smaller than the control mice (supplementary Fig. 2B), a phenotype that is specifically observed in Akt3-null animals (29).

Lipid oxidation is enhanced in PIKE−/− mice. Animal models with lipoatrophy often associate with hyperlipidemia and ectopic lipid accumulation (30). However, significant changes in neither circulating triglyceride (Fig. 5A) nor ectopic lipid deposition in liver (Fig. 5B) were seen in the PIKE−/− mice, suggesting the excessively absorbed lipid during HFD feeding in PIKE-null animals may be metabolized rather than deposited as storage. To test this possibility, we first monitored the frequency of animal movements using open-field locomotor assay (31). Whereas the activity in wild-type mice decreased when they adapted to the test cage, physical movement of...
PIKE<sup>−/−</sup> mice remained substantially higher throughout the experiment in both diet conditions (Fig. 5C). We also examined the metabolic rate using metabolic cages (23). Respiratory exchange ratio was lower in PIKE<sup>−/−</sup> animals in both diet treatments, suggesting that mutant mice have a higher fatty acid catabolism (Fig. 5D). This suggested high lipid oxidation was further supported by the high phosphorylation level of AMPK and ACC in PIKE<sup>−/−</sup> muscle, brown adipose tissue (BAT), and WAT. AMPK phosphorylation was reduced after HFD feeding in wild-type BAT and WAT. However, AMPK in PIKE<sup>−/−</sup> WAT remained highly phosphorylated in both feeding groups (Fig. 5E, first and tenth panels). In parallel, phosphorylation of ACC in PIKE<sup>−/−</sup> BAT and WAT was higher than the control group (Fig. 5E, third, fourth, and 12th panels). Whereas AMPK expression in WAT remained unchanged after HFD feeding, AMPK in BAT was greatly reduced in both genotypes (Fig. 5E, second and 11th panels). Expression of ACC was reduced after HFD treatment in both wild-type and PIKE<sup>−/−</sup> BAT and WAT (Fig. 5E, fifth and 13th panels). Interestingly, PIKE<sup>−/−</sup> BAT has higher ACC expression (Fig. 5E, 13th panel). Similar phosphorylation pattern occurred in both AMPK and ACC in PIKE<sup>−/−</sup> muscle (Fig. 5E, sixth and eighth panels) with unchanged

**FIG. 4.** PIKE knockout mice are protected from diet-induced hyperglycemia by enhanced systemic insulin sensitivity. A: Blood glucose level in fed and fasting (16 h) wild-type (+/+ ) and PIKE knockout (−/−) mice (8–9 months old) that have been fed with chow or HFD for 20 weeks. Results were expressed as mean ± SEM ( *P < 0.05; **P < 0.01 vs. the same genotype treated with different diets; a: P < 0.05 vs. different genotypes treated with the same diet under fasting condition; b: P < 0.001 vs. fed and fasted PIKE<sup>+</sup>/+ mice treated with chow diet; one-way ANOVA, n = 4–7). B: Glucose tolerance test in wild-type (+/+ ) and PIKE knockout (−/−) mice (8–9 months old) that have been fed with HFD for 20 weeks (8–9 months old) after overnight fasting. Blood glucose level was monitored at different time intervals after intraperitoneal injection of glucose (2 g/kg). Results were expressed as mean ± SEM (n = 7; **P < 0.01; ***P < 0.005 vs. the same genotype; b: P < 0.01, c: P < 0.001 vs. the same diet; two-way ANOVA). C: Circulating insulin concentration of wild-type (+/+ ) and knockout (−/−) mice (8–9 months old) that have been fed with chow diet or HFD for 20 weeks (n = 4). Results were expressed as mean ± SEM ( *P < 0.05, **P < 0.01 vs. the same genotype; b: P < 0.01 vs. the same diet; one-way ANOVA). D: Glucose infusion rate in wild-type (+/+ ) and knockout (−/−) mice (8–9 months old) that have been fed with chow diet or HFD for 20 weeks during hyperinsulinemic-euglycemic clamp experiment. Results were expressed as mean ± SEM (n = 9; *P < 0.05, ***P < 0.001 vs. the same diet; c: P < 0.001 vs. the same genotype; one-way ANOVA). E: Enhanced insulin signaling in fasted 3-month-old wild-type (+/+ ) and PIKE-null (−/−) mice fed with chow diet. Mice were administered saline (−) or 5 units human insulin (+) via the inferior vena cava. After 5 min, ingunal WAT and skeletal muscle were isolated and frozen in liquid nitrogen. The phosphorylation of insulin receptor (first panel), IRS-1 (third panel), and Akt (Thr<sup>308</sup> and Ser<sup>473</sup>) (sixth and seventh panels) was determined using specific antibodies as indicated. PI-3 kinases in the tissues were precipitated using anti-p110<sup>α</sup> antibody and their activities were assayed (fifth panel). The expression of total insulin receptor (second panel), IRS-1 (fourth panel), and Akt (eighth panel) was determined to show equal loading. Representative results from three mice of each genotype were shown. F: Insulin elicits higher glucose uptake in fat and muscle of PIKE-null mice. Soleus muscle and ingunal WAT excited from 3- to 5-month-old wild-type (+/+ ) or PIKE knockout (−/−) mice were used in determining the 3H-2-deoxyglucose uptake in the presence of 10 μM/ml human insulin. Results were presented as mean ± SEM (n = 3; *P < 0.05 vs. the same genotype; a: P < 0.05 vs. the same treatment, one-way ANOVA).
Liver phosphor–Thr172-AMPK, phosphor–Ser79-ACC, total AMPK, and ACC antibodies. That have been fed with chow or HFD for 20 weeks. Extracts of inguinal WAT, BAT, and muscle were prepared and immunoblotted with genotype, one-way ANOVA, for 20 weeks.

**FIG. 5.** Enhanced lipid oxidation in PIKE−/− mice. **A:** Serum triglyceride level of wild-type (+/+ ) and knockout (−/− ) mice (8–9 months old) that have been fed with chow or HFD for 20 weeks. Results were expressed as mean ± SEM (n = 4; ***P < 0.001 vs. the same genotype; one-way ANOVA). **B:** Hematoxylin-eosin (H&E) (upper panel) and oil red O (lower panel) staining of liver sections collected from wild-type (+/+ ) and knockout (−/− ) mice (8–9 months old) that have been fed with HFD for 20 weeks. Scale bar represents 50 μm. Representative result of three mice from each genotype is shown. **C:** Spontaneous activity of wild-type (+/+ ) and PIKE knockout (−/− ) mice fed with chow or HFD for 14 weeks. Results were expressed as mean ± SEM (n = 7; *P < 0.05, ***P < 0.001 vs. the same diet). **D:** Oxygen consumption (top panel), CO2 release (middle panel), and respiratory exchange ratio (bottom panel) in wild-type (solid bar) and knockout (open bar) mice fed with chow and HFD for 20 weeks (n = 4). Results were expressed as mean ± SEM ***P < 0.01, ***P < 0.001 vs. the same diet; a: *P < 0.05, c: P < 0.001 vs. the same genotype, one-way ANOVA, n = 4). **E:** Analysis of ACC and AMPK phosphorylation in wild-type (+/+ ) and knockout (−/− ) mice (8–9 months old) that have been fed with chow or HFD for 20 weeks. Extracts of inguinal WAT, BAT, and muscle were prepared and immunoblotted with phosphor–Thr172-AMPK, phosphor–Ser79-ACC, total AMPK, and ACC antibodies. **F:** Elevated fatty acid oxidation in PIKE−/− muscle cells. Rate of 3H-palmitate oxidation was measured in cultured skeletal muscle cells and hepatocytes isolated from wild-type (+/+ ) and PIKE knockout (−/− ) mice. Results were expressed as mean ± SEM (*P < 0.05, one-way ANOVA, n = 5). (A high-quality digital representation of this figure is available in the online issue.)

Therefore, the high physical activity of PIKE−/− mice and enhanced lipid oxidation in BAT, WAT, and muscle may account for their lean phenotype during HFD feeding. The higher AMPK phosphorylation in PIKE−/− WAT also provides a possible explanation for the defective adipogenesis observed, because prolonged AICAR-induced AMPK activation inhibits adipocyte differentiation by diminishing PPARγ and C/EBPα expressions (33,34). Furthermore, agonist-activated AMPK potentiates the insulin-stimulated glucose uptake by activating IRS-1 (35,36), which may explain the enhanced PI 3-kinase and Akt activities in the muscle and WAT of PIKE−/− mice.

FIG. 6. PIKE interacts with insulin receptor and is essential for insulin-suppressed AMPK phosphorylation. A: Diagrammatic representation of various myc-tagged PIKE-A truncates. PIKE-A is a GTPase containing a short NH₂-terminal, a GTPase domain (GTPase) for hydrolysis of GTP, a PH domain for phosphoinositol lipid interaction, and a COOH-terminal region (GAP-ANK) with sequence homology to ARF/GAP protein and ankyrin repeats. B: Mapping of the insulin receptor interaction domain in PIKE-A. Various myc-tagged PIKE-A truncation mutants as shown in A and His-tagged insulin receptor (His-IR) were cotransfected into HEK293 cells. The myc-tagged proteins were immunoprecipitated and the associated insulin receptor was detected using anti-insulin receptor antibody (top panel). Expression of His-IR (middle panel) and various myc-tagged proteins (lower panel) was also detected. C: Fyn phosphorylation of PIKE-A is important for insulin receptor interaction. HEK293
PIKE-A is essential for insulin-suppressed AMPK phosphorylation. Next, we sought to clarify the role of PIKE-A in modulating AMPK phosphorylation. Fyn knock-out (Fyn<sup>−/−</sup>) mice are lipodystrophic with enhanced AMPK activity in muscle and WAT (37). These metabolic characteristics highly resemble the phenotypes of PIKE<sup>−/−</sup> mice. Given that PIKE-A is a substrate of Fyn (38) and Fyn interacts with IRS-1 in an insulin-dependent manner (39), we hypothesized that PIKE-A may form a complex with Fyn and insulin receptor upon insulin stimulation, which is essential for insulin to suppress AMPK activity (40,41). In HEK293 cells, PIKE-A associated with insulin receptor through its NH<sub>2</sub>-terminal (1–72 amino acids) (Fig. 6A and B), in which their interaction could be enhanced by insulin stimulation (Fig. 6C, first panel). However, this interaction was abolished when the Fyn phosphorylation site (Tyr<sup>682</sup> and Tyr<sup>774</sup>) in PIKE-A (PIKE-A YY) was mutated (Fig. 6C, first panel), suggesting Fyn phosphorylation is critical to the formation of PIKE-A/insulin receptor complex. The kinetics of insulin receptor/PIKE-A complex formation inversely correlated with the phosphorylation of AMPK (Fig. 6D, first and sixth panels). Remarkably, neither Thr<sup>172</sup> nor Ser<sup>485</sup>/Ser<sup>491</sup> phosphorylation (42) was altered by insulin in GST-PIKE-A YY—transfected cells (Fig. 4D, sixth and seventh panels), suggesting that PIKE-A binding to insulin receptor is critical to mediate the inhibitory action of insulin on AMPK phosphorylation. On the other hand, Akt phosphorylation was not affected in either wild-type PIKE-A or PIKE-A YY cells in response to insulin (Fig. 6D, fourth panel). The formation of PIKE/insulin receptor/Fyn complex was further demonstrated in muscle tissue. In vivo insulin injection in wild-type mice enhanced the formation of PIKE-A/insulin receptor complex, which was substantially reduced in Fyn<sup>−/−</sup> tissue (Fig. 4G, first panel). This complex was not detected in PIKE-null tissues (Fig. 6E, first panel). Our immunoprecipitation results also confirmed that the association of Fyn and insulin receptor in muscle is insulin dependent (Fig. 6E, second panel). Furthermore, the formation of Fyn/insulin receptor complex was not affected in PIKE-null tissues, suggesting that PIKE-A is not essential for their interaction (Fig. 6E, second panel). Thus, the interaction between PIKE-A and insulin receptor is important for insulin to suppress AMPK phosphorylation, which provides a possible explanation to the enhanced AMPK phosphorylation in PIKE<sup>−/−</sup> WAT and muscle.

**DISCUSSION**

One of the major findings in the current report is that PIKE-A is critical for adipocyte differentiation. Several lines of evidence support the role of PIKE-A in terminal adipocyte differentiation instead of preadipocyte formation. First, the mature adipocyte marker αP2 is significantly decreased during in vitro adipocyte differentiation in PIKE<sup>−/−</sup> MEFs, indicating PIKE-A is important for adipocyte differentiation (Fig. 3B and C). Second, PIKE-A expression is increased in fat tissue development of HFD-fed and ob/ob mice, which highlights its function in the process (Fig. 2H). Lastly, HFD induced comparable preadipocyte marker Pref-1 expression in both wild-type and PIKE<sup>−/−</sup> mice, indicating that formation of new adipocytes is normal in PIKE-null adipose tissue (Fig. 3A). Interestingly, we found a small portion of PIKE<sup>−/−</sup> MEFs was able to differentiate into mature adipocytes (Fig. 3B), and quantitative analysis revealed a small but statistically significant increment of lipid accumulation in PIKE<sup>−/−</sup> MEFs (Fig. 3C). This result indicates that a PIKE-A—dependent mechanism is responsible for some adipocyte differentiation, which also accounts for the existence but not completely the absence of adipose tissue in PIKE<sup>−/−</sup> mice.

Ectopic lipid storage due to adipocyte differentiation defect is associated with hyperlipidemia and liver steatosis (43). However, we could not detect these pathologic conditions in PIKE<sup>−/−</sup> mice (Fig. 5A and B). It is thus reasonable to predict that the lipid spillover from adipocyte is metabolized in mutant animals. Our results that PIKE-null fat and muscle have significantly elevated AMPK and ACC phosphorylation suggest an elevated β-oxidation in these tissues (Fig. 5E), which is further supported by the enhanced fatty acid oxidation rate in the in vitro assay (Fig. 5F) and the low respiratory exchange ratio values (Fig. 5D). AMPK has been viewed as a fuel sensor for glucose and lipid metabolism. Once activated, AMPK initiates a concomitant inhibition of energy-consuming biosynthetic pathways and activation of ATP-producing pathways such as fatty oxidation in mitochondria (44). As a result, most of the lipids absorbed in PIKE<sup>−/−</sup> mice are oxidized as the energy source, which accounts for the lean phenotype during the HFD treatment.

The upregulated phosphorylation of AMPK and its downstream substrate ACC in PIKE-null muscle and adipose tissues indicates that PIKE-A negatively regulates the activities of these enzymes. This notion is further supported by the fact that PIKE-A is critical for insulin to inhibit AMPK phosphorylation in 293 cells (Fig. 6D). This upregulation of AMPK activity in PIKE<sup>−/−</sup> muscle and fat also provides a possible mechanism accounting for the elevated systemic insulin sensitivity, as AMPK and insulin signaling are intimately connected. Agonist-induced AMPK activation increases the glucose uptake in muscle (45). It also potentiates the insulin-stimulated glucose uptake by activating IRS-1 (35,36). A similar observation was made in
adipose tissue that treatment of adipocytes with AMPK agonist AICAR enhanced basal glucose uptake by increasing GLUT4 translocation (46). Long-term activation of AMPK in mice increases the systemic insulin sensitivity and protects animals from HFD-induced obesity and diabetes (34,47), which is in agreement with our observations in PIKE<sup>−/−</sup> mice. It is noteworthy that the alleviated insulin resistance in PIKE<sup>−/−</sup> mice after HFD treatment may be a result of reduced inflammation. Because reduced circulating TNF-α could improve insulin sensitivity and increase AMPK activity (48,49), the low blood TNF-α in PIKE<sup>−/−</sup> mice (Fig. 2G) may also contribute significantly to improve the diet-induced insulin resistance.

Because the whole-body-knockout mice were used in the present study, we cannot exclude the possibility that deletion of PIKE-A in the brain causes a central effect to modify whole-body activity and metabolism. Because brain is the major site to control appetite and body weight (50), where PIKE is highly expressed (Fig. 1D), it is reasonable to suspect that reduced food intake (Fig. 2H) and elevated physical activity (Fig. 5C) in PIKE<sup>−/−</sup> mice are the primary causes of lean phenotype during HFD treatment. However, our data strongly support that peripheral ablation of PIKE-A does play a role in preventing obesity development. First, the feeding behavior is comparable between wild-type and PIKE<sup>−/−</sup> mice fed a chow diet, when lipatrophy is already obvious. Second, in vitro alternative splicing of growth hormone secretagogue receptor transcripts to nuclear mitotic apparatus protein in PC12 cells mediates the antiproliferative actions of nerve growth factor. J Neurosci 1999;19:10747–10756.

In all, our results uncover the novel physiological functions of PIKE-A, which plays important roles in obesity development and the accompanied insulin resistance by regulating AMPK activities negatively. Consequently, less fat is deposited and the associated insulin resistance is ameliorated. Therefore, PIKE-A may represent a potential therapeutic target for obesity and the adjunct insulin resistance.
