Iron can adopt formal oxidation states ranging from $-II^1$ to $+VI$. Iron complexes are used as catalysts in synthetic chemistry for carbon–heteroatom$^1$ and carbon–carbon bond forming reactions.$^4$ Low-valent iron complexes can catalyze cross-coupling,$^5$ cycloisomerization,$^5$ and cycloaddition reactions.$^6$ We are interested in iron catalysis for the identification of useful, previously inaccessible reaction chemistry and report here C–B bond formation by hydroboration of 1,3-dienes. To our knowledge, there are no other examples of Fe-catalyzed hydroboration reactions of olefinic substrates. The allylborane products are formed regio- and stereoselectively with (E)-double bond geometry exclusively and are challenging to access selectively with conventional chemistry.

We have previously reported a 1,4-addition reaction of α-olefins to dienes using an iminopyridine-ferrous chloride complex with magnesium metal as an in situ reducing agent.$^8$ In this Communication, we describe the use of analogous, readily prepared iminopyridine-derived iron complexes as catalysts for the regioselective 1,4-addition of pinacolborane (HBPin) to substituted 1,3-dienes (eq 1).

Allylboration are versatile intermediates employed in oxidation to allylic alcohols,$^{10}$ allylation to give homoallylic alcohols$^{11}$ and amines,$^{12}$ and Suzuki cross-coupling reactions.$^{13}$ Traditional methods to synthesize allylboration involve basic main group organometallics, such as Grignard and organolithium reagents, that are incompatible with electrophilic functional groups.$^{11a}$ While transition-metal-catalyzed hydroboration of olefins has been studied extensively with great success,$^{14}$ hydroboration of dienes to access allylboration is less established. Palladium(0) catalyzes the 1,4-addition of catecholborane to unfunctionalized 1,3-dienes such as 1,3-pentadiene and isoprene to give (Z)-branched allylboration,$^{15}$ and Ni$^{15,16}$ and Rh$^{17}$-catalyzed$^{17}$ reactions are selective for 1,2-addition.

The synthesis of linear (E)-γ-disubstituted allylboration is attractive because, for example, they can afford trisubstituted allylic alcohols stereospecifically and add to electrophiles to generate quaternary stereocenters with control of diastereoselectivity. Challenges in the synthesis of linear (E)-γ-disubstituted allylboration via hydroboration of 1,3-dienes include control of chemoselectivity to favor 1,4- over 1,2-addition, control of regioselectivity to favor C–B bond formation at a single diene terminus, and control of stereoselectivity to favor E-olefin geometry. The hydroboration reaction presented herein controls all three types of selectivity. A general method to synthesize linear (E)-γ-disubstituted allylboration has not been reported previously.$^{18}$

We observed that hydroboration of myrcene (1) to geranylpinacolborane (2a) was catalyzed by the iminopyridine-iron(II) complex 3-FeCl$_2$, upon addition of magnesium metal, after 3 h at 23 °C in 80% yield (eq 1). The combination of ligand, ferrous chloride, and magnesium was necessary for catalysis. Pinacolborane generally afforded allylboration that were stable to air, water, and chromatography on silica gel; other borolanes, such as those derived from catecholborane, were not stable towards hydrolysis or chromatography on silica gel.$^{19}$

![Reaction Scheme 1](image1.png)

![Reaction Scheme 2](image2.png)

Evaluation of different bidentate ligands (see Supporting Information) showed that iminopyridine ligands gave the highest yields for hydroboration. The redox activity of iminopyridine ligands may play a role in effecting efficient catalysis.$^{20}$ Ligand optimization revealed that variation of the substituent of the imine nitrogen modulates the 1,4-regioselectivity to favor either the branched or the linear isomer (eqs 1 and 2). 1,4-Addition of pinacolborane to myrcene (1) catalyzed by 3-FeCl$_2$ produced geranylpinacolborane (2a) in 93:7 (2a:2b) regioselectivity and $>99:1$ E/Z selectivity in 89% overall yield (eq 1). When catalyst 4-FeCl$_2$ was used, the regioselectivity inverted to afford branched allylboration 2b as the major product in 78% isolated yield (92% yield of combined regioisomers, eq 2). The ligand-controlled regioselectivity is of synthetic value and may be set during migratory insertion (see mechanistic hypothesis, Scheme 1).

Hydroboration of various 1,3-dienes occurred within 4 min to 4 h, depending on the substrate and ligand, and proceeds as efficiently with commodity ferrous chloride (98% purity) as with high-purity ferrous chloride (99.998% purity) as iron source. As shown in Table 1,$^{21}$ the regioselectivity for 1,4-hydroboration of 2-substituted dienes increased as the size of the 2-substituent increased: isoprene afforded prenylboronate ester 10a with 90:10 regioselectivity; geranylborane 2a was obtained in 93:7 regioselectivity; 2-cyclohexylbutadiene (11) and 2-dimethylphenylisobutadiene (13) were hydroborated in 94:6 and 99:1 regioselectivity, respectively. The regioselectivity of 1,4-addition to 13 could be inverted from 99:1 to $<1:99$ by using the iron complex 4-FeCl$_2$, which differs only in the iminopyridine substituent from iron complex 3-FeCl$_2$ (entries 6, 7). Both allylboration 14a and 14b are difficult to synthesize otherwise: silaboration of allenes yields 2-borylallylilsilanes.$^{22}$ In addition to 2-substituted dienes, 2,3-disubstituted diene 5 participated in Fe-catalyzed hydroboration to regioselectively give allylboration 6. The 1,4-disubstituted diene 7 was hydroborated efficiently to give allylboration 8. Hydroboration of the 1,2-disubstituted diene (+)-nopalide (15) gave C–B bond formation at the less substituted diene terminus with 98:2 regioselectivity.$^{23}$
The Fe-catalyzed hydroboration can be performed in the presence of electrophilic functionality, such as the ester in 19, that is incompatible with the basic conditions of traditional allylborane syntheses.\(^{11}\) Notably, hydroboration is chemoselective, and 1,4-addition to 1,3-dienes proceeds without hydroboration of isolated olefins such as in 21. We attribute the high chemoselectivity of diene versus olefin hydroboration to the affinity of 1,3-dienes for low-valent iron.\(^{12}\) The Fe-catalyzed hydroboration of all dienes investigated is selective for 1,4-addition to produce allylboranes stereo- and regioselectively. 1,2-Addition products could not be detected by \(^1\)H NMR. The major regiosomers 12a–22a were formed with (E)-double bond geometry exclusively, consistent with the proposed mechanism in Scheme 1. Products with trisubstituted double bonds can otherwise be challenging to synthesize stereoselectively, especially when the substituents are similar in size.\(^{13}\)

Allylic alcohols with trisubstituted double bonds are substrates for asymmetric catalytic reactions, such as Noyori hydrogenation,\(^{26}\) isomerization to generate chiral aldehydes,\(^{27}\) and Sharpless asymmetric epoxidation.\(^{28}\) All reactions require the alcohol substrate to be stereochemically pure with respect to double bond geometry to attain high levels of enantioselectivity. The presented Fe-catalyzed hydroboration provides ready access to allylic alcohols with (E)-trisubstituted double bonds in high stereoselectivity (> 99:1, eqs 3 and 4).\(^{25}\) For example, allylic alcohol 23 was synthesized in two steps by hydroboration of (+)-nopadiene (15) followed by oxidation to provide only E-isomer 23 in 84% yield over 2 steps.

The Fe-catalyzed reaction can also be used in a one-pot hydroboration-allylation reaction, as shown in eq 5. Benzaldehyde was added, subsequent to 1,4-hydroboration of ester 19, to give a 93:7 mixture of homoallylic alcohols 25a and 25b resulting from the two regioisomers 20a and 20b. Homoallylic alcohol 25a was formed as a single diastereomer, as determined by \(^1\)H NMR spectroscopy. Lactone formation afforded 26 in 85% yield as a single diastereomer. Alcohol 25a and \(\delta\)-lactone 26 both contain an all-carbon quaternary center; the relative stereochemistry in 25a and 26 is a result of the E-

In conclusion, we report a chemo-, regio-, and stereoselective Fe-catalyzed hydroboration of 1,3-dienes to afford linear (E)-γ-disubstituted allylboration. The iminopyridine-Fe-catalyzed reaction provides access to allylboration—versatile building blocks—that are challenging to prepare by traditional allylboration syntheses or other known transition metal-catalyzed reactions. The hydroboration reaction demonstrates previously unknown reactivity for iron.
