Aryl fluorides are valuable compounds as pharmaceuticals and as tracers for positron-emission tomography. The general synthesis of complex, highly functionalized aryl fluorides in which the carbon–fluorine bond is introduced at a late stage of the synthesis is a challenge unmet by conventional fluorination methods. We recently communicated that aryl boronic acids can be converted into aryl fluorides via reaction of stoichiometric aryl palladium complexes with the electrophilic fluorination reagent Selectfluor™ (1) (eq 1). Two potential mechanisms for carbon–fluorine bond formation are palladium–boron bond cleavage by the electrophilic fluorination reagent and oxidation of the palladium center to form a discrete high-valent palladium fluoride followed by reductive elimination to form a carbon–fluorine bond.

In this communication we present the carbon–fluorine bond formation from two high-valent aryl palladium fluoride complexes. The observation of high-valent palladium fluorides may afford valuable mechanistic insight to better understand carbon–fluorine bond formation mediated by transition metals.

Transition-metal-mediated carbon–fluorine bond formations are rare. Three processes, including our own work, have been reported using palladium complexes and electrophilic fluorination sources. In 2006, Sanford published a palladium catalyzed fluorination of phenylpyridine derivatives and related substrates in which carbon–hydrogen bonds proximal to the pyridine directing group were fluorinated (microwave, 100–150 °C, 1–4 h, 33–75% yield). Vigalok reported in 2008 the formation of 1,4-difluorobenzene and 4-fluoroiodobenzene in 10% and 90% yield, respectively, from an aryl-iodo-bisphosphine palladium (II) complex upon treatment with 1-fluoro-2,4,6-trimethylpyridinium tetrafluoroborate. For all three processes, the intermediacy of a high-valent palladium fluoride followed by reductive elimination to form the carbon–fluorine bond and a palladium (II) complex was discussed as a potential reaction pathway. In none of the cases, however, was a high-valent palladium intermediate characterized or observed. In fact, a carbon–fluorine bond formation to form an aryl fluoride by concerted aryl–fluorine reductive elimination from a well-defined transition metal fluoride, while implicated, has not been substantiated in the literature from any transition metal in any oxidation state.

Scheme 1 shows a reaction sequence to convert a boronic acid into the corresponding arylfluoride. We found that pyridyl-sulfonamide ligands such as 2 are well suited for the fluorination reaction, because they serve as ancillary ligands to support arylpalladium complexes such as 5, which afford aryfluorides regiospecifically upon treatment with Selectfluor™ in high yield (87% in the presented case). The palladium (II) acetate complex 3 was obtained in 99% yield from pyridyl-sulfonamide 2 and palladium (II) acetate in the presence of three equivalents of pyridine. Transmetallation using 4-tert-butylphenylboronic acid (4) afforded the air- and water-stable yellow aryl palladium complex 5 in 80% yield. Fluorination of 5 with Selectfluor™ in acetonitrile at 50 °C gave 4-tert-butylfluorobenzene (6) in 87% yield within 30 min.

Under the reaction conditions that afforded 87% yield of 6 (acetonitrile, 50 °C), we did not observe a high-valent palladium fluoride intermediate by NMR, but a reversible color change from yellow to orange upon addition of 5 to Selectfluor™ suggested the formation of a discrete intermediate. To evaluate the mechanistic hypothesis that pyridyl-sulfonamide-stabilized aryl palladium complexes such as 5 can afford carbon–fluorine bond formation via well-defined discrete palladium fluorides, we sought to design an analog of 5 that would afford an observable palladium (IV) fluoride upon oxidation with Selectfluor™. Rigid ligands have been shown to stabilize high-valent metal centers including palladium (IV). We therefore synthesized the palladium (II) derivative 8, in which a rigid, chelating benzoquinolinyl ligand substitutes the aryl and pyridyl ligands of 5 (eq 2). Treatment of the benzoquinolinyl palladium acetate dimer 7 with one equivalent of the pyridyl-sulfonamide ligand 2 in methylene chloride at room temperature afforded the aryl palladium complex 8 in 95% yield as an analytically pure yellow solid within 20 min.

Fluorination of 8 in acetonitrile at 50 °C afforded 10-fluorobenz[hl]quinoline (10) in 94% yield (Scheme 2). Moreover, we observed a deep purple, well-defined intermediate by ‘H and 13C NMR, which was not contaminated with either 8 or 10 and had a hal-life of ca. 70 minutes in acetonitrile solution at 23 °C. The NMR resonances, including an 19F NMR resonance at –278 ppm, are consistent with the terminal palladium (IV) fluoride 9; the instability of 9 precluded isolation and purification for additional characterization. When the acetonitrile solution of 9 was subsequently heated to 50 °C, reductive elimination
The two fluoride substituents are mutually cis (IV) difluoride crystallized associated with the constant to palladium of 113 °C when compared with two discrete palladium (IV) fluoride complexes. Our data is consistent with a well-defined reductive elimination and provides insight into carbon–fluorine bond formation from arylpalladium complexes.
