Abstract

Background: Ozone, a pollutant known to induce airway hyper-responsiveness (AHR), increases morbidity and mortality in patients with obstructive airway diseases and asthma. We postulate oxidized lipids mediate in vivo ozone-induced AHR in murine airways.

Methodology/Principal Findings: Male BALB/c mice were exposed to ozone (3 or 6 ppm) or filtered air (controls) for 2 h. Precision cut lung slices (PCLS; 250 μm thickness) containing an intrapulmonary airway (~0.01 mm² lumen area) were prepared immediately after exposure or 16 h later. After 24 h, airways were contracted to carbachol (CCh). Log EC₅₀ and E₅₀ values were then calculated by measuring the airway lumen area with respect to baseline. In parallel studies, dexamethasone (2.5 mg/kg), or 1-aminobenzotriazol (ABT) (50 mg/kg) were given intraperitoneal injection to naive mice 18 h prior to ozone exposure. Indomethacin (10 mg/kg) was administered 2 h prior. Cell counts, cytokine levels and liquid chromatography-mass spectrometry (LC-MS) for lipid analysis were assessed in bronchoalveolar lavage (BAL) fluid from ozone exposed and control mice. Ozone acutely induced AHR to CCh. Dexamethasone or indomethacin had little effect on the ozone-induced AHR; while, ABT, a cytochrome P450 inhibitor, markedly attenuated airway sensitivity. BAL fluid from ozone exposed animals, which did not contain an increase in neutrophils or interleukin (IL)-6 levels, increased airway sensitivity following in vitro incubation with a naïve PCLS. In parallel, significant increases in oxidized lipids were also identified using LC-MS with increases of 20-HETE that were decreased following ABT treatment.

Conclusions/Significance: These data show that ozone acutely induces AHR to CCh independent of inflammation and is insensitive to steroid treatment or cyclooxygenase (COX) inhibition. BAL fluid from ozone exposed mice mimicked the effects of in vivo ozone exposure that were associated with marked increases in oxidized lipids. 20-HETE plays a pivotal role in mediating acute ozone-induced AHR.

Introduction

Ozone, a potent oxidizing environmental pollutant, exacerabates obstructive lung diseases such as asthma and COPD, and increases hospitalization of patients [1,2]. Ground-level ozone markedly impacts on human lung health and the US Environmental Protection Agency recently announced a stricter standard for the National Ambient Air Quality Standard for ozone at 0.075 ppm/8 h, replacing the previous limit of 0.084 ppm/8 h [3].

Controlled ozone exposure of varying durations and concentrations to humans induces airway hyper-responsiveness (AHR) commonly associated with increased airway inflammatory infiltrate [4]. Ozone-induced inflammation predominantly consists of neutrophils, that traffic, in part, to the airway due to increases in levels of cytokines and chemokines: IL-6 and IL-8 [5] among others. Studies suggest that airway sensitivity to contractile agonists is dependent on the presence of neutrophilia [6]; however, patients that develop the greatest decrements in lung function following ozone exposure do not necessarily correlate with the highest levels of neutrophilic inflammation [7,8,9,10] suggesting a neutrophil independent mechanism that promotes AHR.

In vivo animal models of ozone-induced AHR have predominately examined the chronic or long-term effects following ozone exposure (12–18 h) that in part focuses attention on the presence of an inflammatory infiltrate [11,12,13]. To date, few investigators have characterized the earliest signals after ozone exposure that mediate AHR before infiltrating inflammation occurs. Further, in vivo studies have exclusively examined airway functional assessments of the central airways despite evidence that the lower airways and proximal acinar regions are the most affected [14]. Though multiple protein, peptide, chemical, and lipid mediators

can cause increased AHR, the identification of the specific mediator(s) of the earliest response has not been achieved.

Eicosanoids, the bioactive products of arachidonic acid (AA) are particularly intriguing candidates, as they are generated rapidly and are known to modulate AHR. These include the cyclooxygenase (COX-1 and 2), prostaglandins (PG) E2 and F2, the lipoxigenase (LOX) dependent leukotrienes (LTs), or the cytochrome P450 (CYP) dependent hydroxyeicosatetraenoic acids (HETEs) or epoxyeicosatrienoic acids (EETs). Many of these eicosanoids are increased in the lung following exposure of humans to ozone [15, 16]; however, to date, whether HETEs or EETs produced via the CYP dependent pathways modulate ozone-induced AHR remains unstudied. 20-HETE, excreted primarily as a glucuronide conjugate in urine [17], is generated by the \( \omega \)-hydroxylation of AA by a CYP1A enzyme found predominantly in the heart, kidney and lung [18, 19, 20]. BALB/c mice express CYP1A12 in the lung both constitutively and following IL-1\( \beta \) instillation [21]. CYP4A1 and 4A2 subtypes have also been localized to rat bronchial smooth muscle and epithelial cells and thus, thought to play a role in regulating airway smooth muscle tone [22]. Although the CYP1A12 is most studied source of 20-HETE, whether other CYPs contribute is unknown.

Using the precision-cut lung slice (PCLS) technique, we characterized the earliest effects of ozone exposure in mice by specifically examining the sensitivity of intra-pulmonary airways \( \alpha \) \( \text{vaso} \) at a time immediately after ozone exposure but before airway inflammatory cell infiltration. We hypothesize that ozone acutely induces AHR in a neutrophil-independent manner, through the oxidation of AA to generate 20-HETE.

Materials and Methods

Animals

Experiments were performed on male BALB/c mice between 8 and 12 weeks of age obtained from Charles Rivers Laboratories (Malvern, PA). Animals received water and food ad libitum. All mice used in this study were housed under pathogen-free conditions. The protocol was approved by the Institutional Animal Care and Use Committee of the University of Pennsylvania.

Reagents

Carbachol (CCh), Low Melting Point Agarose (IX-A), Ham’s F-12 medium (supplemented with 10% FBS, 2 mM glutamine, 100 U/mL penicillin, 100 \( \mu \)g/mL streptomycin, pH 7.6), di-isopropylethyamine (DIPEA), 2,3,4,5,6-pentamethoxyphenethylamine (PFB-Br) and solvents were purchased from Sigma-Aldrich (St. Louis, MO, USA). Heavy labeled eicosanoids and standards for quantification were purchased from Cayman Chemical Co. (Ann Arbor, MI, USA). HPLC-grade hexane, isopropanol and ethanol were obtained from Fisher Scientific Co. (Fair Lawn, NJ, USA). ACS-grade ethanol was obtained from Pharmco Products Inc. (Brookfield, CT, USA). Gases were supplied by BOC Gases (Lebanon, NJ, USA). Chiralpak AD-H column was obtained Chiral Technologies (West Chester, PA, USA). All other reagents were obtained from Sigma (St. Louis, MO), unless otherwise stated.

Ozone Exposure

Male BALB/c mice were exposed to ozone for 2 h at concentrations of either 3 ppm or 6 ppm; control mice received filtered-air for the same period of time, both groups being deprived of food and water during this time. Ozone was generated as previously described [23].
ELISA was carried out as per instructions of the kit (R&D Systems), samples were quantified by the comparison of unknown read-outs from a standard curve \( r^2 = 0.99 \). Data were expressed as mean ± SEM; \( n \) = number of mice.

**Oxidized Lipid Assessment**

BAL fluid from animals administered dexamethasone, indomethacin or ABT and exposed to ozone (6 ppm, 2 h, \( T = 0 \) h) or filtered air was collected and oxidized lipids were measured.

**Preparation of Eicosanoid-PFB Derivatives.** The PFB derivatives were prepared by adding to the dry extract or standards in methylene chloride (100 \( \mu L \)), 100 \( \mu L \) of DIPA in methylene chloride (1:19, v/v) followed by 100 \( \mu L \) of PFB-Br in methylene chloride (1:9, v/v) and the solution was shaken at room temperature for 30 min. The solution was evaporated to dryness under a nitrogen stream at room temperature, and re-dissolved in 100 \( \mu L \) of hexane/ethanol (97:3, v/v) for mass spectrometry analysis. A 20 \( \mu L \) aliquot was injected each time.

**LC.** Normal-phase chiral LC was performed using a Waters Alliance 2690 HPLC system (Waters Corp., Milford, MA, USA). Gradient elution was performed in the linear mode. A Chiralpak AD-H column (250x4.6 mm i.d., 5 \( \mu m \); Daicel Chemical Industries, Ltd., Tokyo, Japan) was employed with a flow rate of 1 mL/min. Solvent A was hexanes and solvent B was 2-propanol/hexanes (6/4, v/v). The linear gradient was as follows: 2% B at 0 min, 2% B at 3 min, 3.6% B at 11 min, 8% B at 15 min, 8% B at 27 min, 50% B at 30 min, 50% B at 35 min and 2% B at 37 min. The mobile phase was maintained at 30°C.

**MS.** A TSQ Quantum Ultra AM mass spectrometer (Thermo Analytical, San Jose, CA, USA) was employed for LC-MS analyses. It was equipped with an APCI source and used in the ECAPCI negative ion mode. The operating conditions and MRMs transitions were as described previously [26,27].

**Data Analysis.** All data analysis was performed using Xcalibur software, version 2.0 SR2 (Thermo Analytical) from raw mass spectral data. Calibration curves were plotted using a linear regression of peak area ration of analytes against internal standard. Calibration curves were prepared in the range from 10 to 1000 pg/mL. Samples were stored in hexanes/2-propanol (95/5,v/v) at -20°C. Typical regression lines for 20-HETE (\( y = 0.0007x +0.0007; r^2 = 0.983 \)), PGE2 (\( y = 0.0014x +0.3215; r^2 = 0.999 \)), PGD2 (\( y = 0.0034x -0.01255; r^2 = 0.999 \)). Concentrations of bioactive lipids were calculated by interpolation from the calculated regression lines.

**Eicosanoid Quantification.** Assays were conducted using a modification of methods described previously [26,27]. Briefly, a mixture of 12 heavy isotope internal standards \([^{2}H_{3}]\)-5(S)-HETE, \([^{2}H_{3}]\)-12(S)-HETE, \([^{2}H_{3}]\)-15(S)-HETE, \([^{2}H_{3}]\)-PGF2\( \alpha \), \([^{2}H_{3}]\)-PGD2, \([^{2}H_{4}]\)-LTB4, \([^{2}H_{4}]\)-PGF2\( \alpha \), \([^{2}H_{4}]\)-11(B)-PGF2\( \alpha \), and \([^{2}H_{4}]\)-8(S)-PGF2\( \alpha \) (1 ng each) and \([^{2}H_{6}]\)-5-oxoETE, \([^{2}H_{6}]\)-20-HETE (10 ng) was added to a BAL samples (0.3 mL or 0.2 mL) followed by 1 mL of PBS 1M, pH 6.8. After standing for 10 min at room temperature to allow for equilibration, the samples were acidified to pH 4 with 5.5% formic acid, and then extracted with 75% tert-butylmethyl ether(TBME)/hexanes (5 mL). The organic layer was evaporated to dryness under nitrogen, and oxidized lipids in the residue are converted to PFB derivatives. Levels of detection are less than 1.0 pg.

**CYP Enzyme Quantification by qRT-PCR**

RNA was extracted from whole murine lungs following ozone exposure (6 ppm; 2 h; \( T = 0 \) h). Methods were followed as previously mentioned [28]. Briefly, reverse transcription was completed using the Applied Biosystems High-Capacity cDNA Reverse Transcription Kit (4375222) and protocol. cDNA sample was then analyzed for target gene expression of the listed CYP4a gene primer sets, with an Applied Biosystems StepOnePlus quantitative real-time PCR machine using TaqMan qPCR. Beta-Actin, mouse (4352993) was used as an endogenous control. Standard (~2 h) reaction protocol was followed. \( \Delta C_{T} \) and \( \Delta \Delta C_{T} \) were calculated as per the manufacturer and graphed. Each sample was run in triplicate and the mean value determined. The mean (±SEM) values for the delta C Ts for all experiments are shown on the graph. The following TaqMan primer sets were purchased from Applied Biosystems:

- Beta-actin, CYP4a12a: Mm00514494_m1; Cyp4a12b - Mm00653431_g1; H 4a14 - Mm00483123_m1; Cyp4a10 - Mm01188913_g1; Cyp4x1 - Mm01181487_m1; Cyp4a29 - Mm01188902_g1 Cyp4b1 - Mm01193710_m1.

**Results**

**Ozone increases murine airway sensitivity to carbachol**

To determine whether agonists induce small airway narrowing in murine PCLS, slices were incubated with cumulative doses of carbachol and luminal narrowing was then determined. Carbachol abrogated airway luminal diameter with a log EC\(_{50}\) value of -0.18±0.15 \( \mu M \) (EC\(_{50}\) value: 0.65 \( \mu M \)). Additionally, \( F_{\text{max}} \) (67±0.5%) of this effect was observed at a concentration of 100 \( \mu M \) (Figure 1A). Intra-pulmonary airways in slices from mice exposed to 3 ppm ozone exhibited an increase in airway sensitivity to carbachol when lungs were excised 16 h after the exposure (Figure 1B). The log EC\(_{50}\) or \( F_{\text{max}} \) values of murine airways from lungs excised immediately after a 3 ppm ozone exposure (\( T = 0 \) h) did not change from mice exposed to filtered air. Lungs removed 16 h after the 3 ppm ozone exposure yielded a significant increase in \( F_{\text{max}} \) and decrease in log EC\(_{50}\) values: 90±2.13\% (\( P = 0.02 \)) and -0.31±0.12 \( \mu M \), \( P = 0.04 \) respectively (Figures 1B). Airways from lungs excised immediately following a 6 ppm concentration of ozone demonstrated a dramatically increase in airway responsiveness to carbachol; as shown by a significant increase in the \( F_{\text{max}} \) values from 71.8±11.1\% to 99.1±0.36\% (\( P = 0.04 \)) and a decrease in log EC\(_{50}\) values from -0.20±0.16 \( \mu M \) to -0.81±0.13 \( \mu M \) (\( P = 0.01 \)). An increase in airway sensitivity was also seen, but to a lesser extent, when airways were removed 16 h after the 6 ppm ozone exposure. Although no significant increase in \( F_{\text{max}} \) was seen despite a 19.5\% change, a significant decrease in carbachol log EC\(_{50}\) values was evident: 0.08±0.13 \( \mu M \) vs. -0.32±0.05 \( \mu M \) (\( P = 0.01 \)) (Figure 1C). Airway sizes were not significantly different at baseline suggesting that no airways were partially contracted before the CCh-induced contractions were carried out.

**Increases in BAL cell counts and keratinocyte-derived cytokine (KC) levels were only observed 16 h after ozone exposure**

To characterize biomarkers of ozone-induced inflammation, BAL cell profiles and chemokine levels were measured in the mice exposed to ozone or filtered air. Our previous studies [23] show that 3 ppm of ozone exposure in mice increased BAL cell counts compared to filtered air exposed mice when taken 12 h after exposure. BAL cell counts and KC levels were obtained from mice exposed to 6 ppm ozone immediately and 16 h after exposure. A 10 fold increase in total cell counts was seen in mice at 16 h after a 6 ppm ozone exposure, but no increase was seen when sacrificed immediately (data not shown). Differential cell counts identified a significant increase in both alveolar macrophages and neutrophils from BAL fluid retrieved 16 h after, but not immediately following exposure (Figure 2A). Levels of KC, the murine homolog of IL-8,
This page contains scientific text discussing the effects of ozone exposure on murine airways. Key findings include:

- Ozone exposure increases murine airway sensitivity to carbachol (CCh).
- BAL fluid from ozone-exposed mice induces AHR in slices from naive mice.
- Eicosanoid production in murine BAL following ozone exposure.
- Initial hypothesis that cytokine, chemokine or growth factor known to increase AHR was released into the BAL fluid in response to ozone was tested.

Graphs and tables illustrate the cellular and molecular changes observed.

For a detailed understanding, please refer to the full text of the publication.
relatively equal amounts, and RNA levels were not significantly affected by ozone exposure.

**CYP inhibition, but not dexamethasone nor indomethacin attenuates ozone-induced AHR**

To determine whether CYP activity was required to induce eicosanoid-mediated AHR, animals were administered dexamethasone, ABT (18 h) or indomethacin (2 h) prior to ozone exposure (6 ppm; 2 h; T = 0 h). Ozone exposure caused a leftward shift in the concentration-response curve as shown in Figure 6A–C. The pre-administration of dexamethasone had little effect on the ozone-induced increase in airway sensitivity; nor did the pre-administration of indomethacin. Our previous studies have shown that this concentration and time course of dexamethasone inhibited allergen-induced airway inflammation in mice (data unpublished), and the current data also showed significant PG inhibition following indomethacin administration (Figure 4A). The CYP inhibitor, ABT, however completely abrogated the effects of ozone on CCh-induced airway luminal airway narrowing. \( E_{\text{max}} \) values (ozone: 94.6 ± 1.5% vs. ozone + ABT: 81.7 ± 4.7% \( P = 0.002 \)). In none of the 3 experiments did the drug in question have an effect on air-exposed animals.

**20-HETE increases murine airway sensitivity to carbachol**

Having demonstrated that the inhibition of the production of 20-HETE augmented the ozone-induced AHR, lung slices containing an airway from naive mice were incubated over-night with 20-HETE (0, 1.0 and 10 ng/mL/0, 3.1, 31.0 nM) to determine whether 20-HETE mediates AHR. Airways were contracted to carbachol. As shown in figure 7, 20-HETE increased the maximum bronchoconstriction and increased airway sensitivity by 16% in the \( E_{\text{max}} \) and significantly decreased in log EC50 values compared to airways incubated in the absence of 20-HETE. A lower concentration of 20-HETE (1 ng/mL) significantly increased airway sensitivity without increasing the maximum contraction. 20-HETE (20 ng/mL/62 nM) alone had little effect on basal bronchomotor tone in naive slices.

**Discussion**

Although ozone induces exacerbations of asthma and COPD, and has also been implicated in accelerating cardiovascular disease, the precise cellular and molecular mechanisms are poorly described. Compelling evidence suggests that ozone induces
airway inflammation manifested by increases in neutrophil number and levels of tumor necrosis factor-α and IL-1β. To date, the role of inflammation in mediating ozone-induced AHR remains controversial. Further, studies suggest uncoupling of airway inflammation and AHR after ozone exposure in humans [7,8,9,10].

The PCLS technique serves as a suitable model to measure ozone-induced AHR ex vivo as demonstrated by an increase in airway sensitivity to a muscarinic agonist following ozone exposure (3 ppm; 2 h; T = +16 h; Figure 1B); compared to air-matched controls. Increased levels of neutrophils were also evident. This was previously shown in a model of pulmonary resistance and was associated with an increase in trafficking cells in the BAL fluid, specifically neutrophils [23]. Following exposures of the same concentration of ozone, but at a time where no infiltration cells were present (3 ppm; 2 h; T = 0 h: Figure 1B); no change in airway sensitivity compared to air-controls was observed. After mice were exposed to increased concentrations of ozone (6 ppm), at a time of increased neutrophils in the BAL fluid an increase in airway sensitive to carbachol was observed (6 ppm; 2 h; T = +16 h: Figure 1C). Interestingly, when the time between ozone exposure and animal sacrifice was shortened from 16 to 0 h, AHR was still evident despite no increase in total cell number, neutrophils and KC levels, in the BAL fluid. Despite studies specifically examining neutrophil-dependent AHR [12,13], only a few in vivo rodent [29,30], and human studies [8,10] have also noted an increase in airway sensitivity lacking a correlation with early airway inflammation. One study exposed neutrophil-depleted rats to ozone (1 ppm) for 8 h and concluded that neutrophils did not play a significant role in the acute ozone-induced early epithelial damage seen in non-neutrophil-depleted rats [31]. One must therefore ask if an ozone-induced increase in IL-8 that attracts neutrophils into the lung is responsible for the latent AHR; what mechanism is causing the early phase AHR seen in our study? To determine whether the inhalation of ozone induced the release of a non-immunological mediator, or was directly modulating airway smooth muscle function rendering it more contractile; BAL fluid from mice exposed to ozone (6 ppm; 2 h; T = 0 h) or filtered air was incubated overnight on lung slices from naïve mice. Airways on naïve lung slices incubated with BAL fluid from ozone-exposed mice were more responsive and more sensitive to carbachol, as defined by an increase in the maximum contraction and a decrease in the log EC50 values respectively, than those incubated with BAL fluid from air-exposed mice. These data suggest that ozone promotes AHR via secretion of a soluble mediator from the airway into the BAL fluid.

Eicosanoids are increased in the lungs following ozone exposure [15,16,32]. Alfaro et al. reported that subjects with more sensitive airways had a greater amount of PGE2, 8-iso-PGF2α, and LTD4 in the exhaled breath condensate than subjects with less sensitive airways following an acute exposure to ozone [16]. In the present study, BAL fluid from mice exposed to ozone (6 ppm, 2 h, T = 0 h) was analyzed for quantities of oxidized lipids. Our targeted lipidomics approach for the analysis of BAL fluid revealed that 20-HETE levels were significantly increased upon exposure of mice to ozone. These data suggest that either CYP4A isoforms, responsible for 6-hydroxylation of AA, were up-regulated by ozone treatment [33], or that increases in AA substrate was generated leading to increases in 20-HETE, or that a combination of these mechanisms were in play. When the cytochrome P450 inhibitor ABT was administered 18 h prior to exposure to ozone, the levels of 20-HETE in BAL were reduced by 82%. This is similar to the 84% reduction of renal cortical 20-HETE formation observed in Sprague-Dawley rats treated with similar levels of ABT [34]. The decreased concentrations of 20-HETE in BAL fluid coincided with the complete reversal of the ozone-induced increase in airway sensitivity, suggesting that 20-HETE production played an important role in the AHR when no infiltrating inflammatory cells or mediators were present. The lack of attenuation of the other HETEs suggests the specificity of ABT to 20-HETE in the murine model. Studies have suggested that 1-ABT is a non-selective inhibitor of CYP enzymes [35]; however, the same concentration as was used in the present study demonstrated a fairly selective inhibition of the CYP1A/CYP1F catalyzed formation of 19-and 20-HETE in Sprague Dawley kidneys with no inhibition of epoxygenases [34]. In the present study, no other HETEs were inhibited following 1-ABT administration suggesting it to be selective to the oxidized lipids that were measured. Future studies

Mice were administered either dexamethasone (2.5 mg/kg) or ABT (50 mg/kg) 18 h prior or indomethacin (10 mg/kg) 2 hr prior to ozone (6 ppm, 2 h; T = 0 h) exposure, with control mice exposed to air. BAL fluid was retrieved and analyzed for eicosanoids using mass spectrometry. Data (n = 4) is expressed as mean ± SEM (nM). ND = Not detected. doi:10.1371/journal.pone.0010235.t001

Ozone and 20-HETE in Airways
may warrant the use of the more selective 20-HETE synthesizing enzyme inhibitor HET0016 [35]. PGE₂ and PGF₂α were two of the other most abundant eicosanoids detected in the BAL after ozone treatment (Figure 4) and are known to induce AHR; however, they were still present despite the ABT-induced decrease in airway sensitivity. The non-selective COX-inhibitor, indomethacin reduced the levels of PGE₂, PGF₂α, and PGD₂ levels by 100%, 100%, and 93%, respectively (Table 1) but had no effect on the ozone-induced increase in airway sensitivity, suggesting that PGs do not play a significant role in this model of AHR. Indeed, other studies have shown no evidence of indomethacin inhibiting early phase ozone-induced airway hyper-responsiveness, and have suggested other arachidonic acid metabolites to be responsible for the increase in airway sensitivity [36,37]. However, Nakando and colleagues demonstrated an increase in neutrophils immediately after ozone exposure, suggesting that neutrophil-dependent AHR was evident, that may be independent of AHR induced by increases in oxidized lipid products in their study. Hazucha and colleagues also demonstrated a lack of an effect with COX inhibition on an ozone-induced increase of airway resistance in human subjects, when PGE₂ and thromboxane were reduced [38]; however, like Nakando, but unlike the present study, neutrophils were also present. In addition, ozone exposure of mice deficient in PGE-synthase, which is needed for the generation of PGE₂, had little effect on AHR (unpublished data). Dexamethasone pre-treatment had no effect on the oxidized lipids in the BAL, or on the ozone-induced AHR. This could, in part, be due to steroids having little or no effect on models of oxidative stress [39,40]. LOX inhibitors were not used as levels of LTs were not shown to be increased following the exposure of ozone, thus not thought to play a role in the AHR seen in the present study. Thromboxane levels were not detected following any condition.

Collectively, our data suggests that 20-HETE plays a significant role in the neutrophil-independent AHR because the inhibition of

20-HETE production by ABT attenuated ozone-induced increases in airway sensitivity, when other HETEs or PGs were not affected. Previous studies have suggested that 20-HETE modulates airway tone [22,41,42]; however, our study failed to show evidence of the direct effect on airway contraction in murine airways. Incubation of 20-HETE with murine lung slices, however, increased its contractile sensitivity to carbachol as compared with diluent treated slices. Concentrations of 20-HETE used were comparable to those measured in the BAL fluid following ozone exposure. Concentrations 100 fold lower than those measured in the BAL fluid were also shown to increase sensitivity of airway contraction. The mechanism of 20-HETE-induced AHR is unknown at this time and warrants further investigation. Although the slices are exposed to ozone for 2 hours, airway functional assessment is not carried out until the next day. This is due to a limitation of the preparation in that although lung slices are prepared immediately, the removal of agarose and the allowance of time for the airway to revert back to basal tone following slicing is required. Within this time, the effects of the ozone exposure are still at play at the intracellular level. Therefore, to mimic this as close as possible,

Figure 5. Ozone did not increase CYP enzymes measured. mRNA was extracted from whole lungs of mice exposed to ozone (6 ppm; 2 h; T = 0 h) and CYP isotypes were quantified using Taq Man qPCR, as described in the methods. Data was run in triplicate and expressed as mean ± SEM (n = 5 in each group).
doi:10.1371/journal.pone.0010235.g005

Figure 6. CYP inhibition abrogates ozone-induced increases in airway sensitivity. Mice were administered either (A) dexamethasone (2.5 mg/kg; 18 h prior); (B) indomethacin (10 mg/kg; 2 h prior); or (C) ABT (50 mg/kg; 18 h prior) to ozone (6 ppm, 2 h; T = 0 h) exposure, with control mice exposed to filtered air. Lung slices were prepared, and airways were contracted to carbachol (CCh) to create concentration response curves, from which (D) log EC50 values and (E) maximum contractions were calculated. Data is expressed as Mean ± SEM shown. NS = Non-significant; **** P<0.0001 vs. control; ## P<0.01 vs. ozone. At least 6 animals were used in each group, and never more than 10.

20-HETE and BAL fluid was incubated over-night to time-match the *ex vivo* study.

To date, only CYP4A12a and 4A12b have been shown to generate 20-HETE from AA [43]. In humans, CYP4F2 and CYP4F3B play a major role in generating 20-HETE. In mice, however, members of the CYP4F family modify the ω-, and ω-1 positions of AA to generate 18-HETE and 19-HETE. Therefore, though we determined the relative amounts of murine CYP4A family members and their relative change in response to ozone, we focused predominantly on the relative expression of the isoforms CYP4A12a and CYP4A12b in response to ozone. As shown in figure 5, CYP4A12a and CYP4A12b expression, as determined by qRT-PCR, were similar. Ozone had little effect on the relative expression of either gene product. Therefore, the induction of 20-HETE must be regulated at a step proximal to CYP4A expression and is likely due to increases in substrate delivery by increased generation of AA via cPLA2 activity or at the re-acylation of AA into membrane phospholipids as previously described [44]. Levels of AA were increased in murine BAL fluid following ozone exposure (Figure 6D), therefore providing increased levels of substrate for the CYP enzymes to convert to 20-HETE. Surprisingly, not all oxidized lipid mediators downstream from AA were increased such as the LTs, suggesting that CYP enzyme activity may be another mechanism modulating AHR following ozone exposure. Macrophages present in the lung tissue may also be a source of 20-HETE production.

It is worth emphasizing that the current study is taking a snapshot immediately after ozone exposure, eliminating infiltrating inflammation by creating the slices, and hypothesizing that a CYP4A dependent pathway is (directly or indirectly) responsible for the AHR shown. A limitation of the current study is that we cannot rule out the exact mechanism as a time-course of the supernatants post-ozone post-slicing was not carried out; however, an advantage is that we can eliminate the role of infiltrating cells. This will lead us to our follow-up studies.

Although we recognize the concentration of ozone needed to achieve the phenomenon of neutrophil-independent AHR is greater than that defined by the EPA to be hazardous to humans [3], the fractional deposition of ozone in mice is only 25% compared to 100% for humans. The EPA also recognizes an exposure time of 8 h which is much longer than the 2 h duration in the present study. Our data suggests that 20-HETE generated by ozone may represent one of the earliest and most robust signals promoting ozone-induced AHR.

In summary, eicosinoids released into the airway increased following ozone that was not attenuated by dexamethasone or...
indomethacin. Only inhibition of 20-HETE production attenuated both the ozone-induced elevated levels 20-HETE and AHR. We postulate that the increased 20-HETE is derived from an increase in AA, as well as the possibility of increased CYP activity, but not by an increase expression of CYP enzymes. Modulation of the production of 20-HETE may serve as a new therapeutic target to prevent ozone-induced exacerbations of asthma and COPD or serve as an important biomarker of oxidative stress in the airways.
