Effects of thyroid hormones on major cardiovascular risk in acute coronary syndromes
A Bayrak, A Bayr, K Uçar Karabulut, Selçuk University, Meram Faculty of Medicine, Konya, Turkey; Selçuk University, Selçuklu Faculty of Medicine, Emergency Department, Konya, Turkey; Emergency Service of Şırnak State Hospital, Şırnak, Turkey

Introduction In this study we aimed to investigate the relationship between thyroid hormone abnormalities and major cardiovascular events and sudden cardiac death at 3 and 6 months after discharge in patients who were admitted to the Emergency Department with acute coronary syndrome.

Methods The study group included 110 patients without known thyroid dysfunction who were referred to the Emergency Department with acute coronary syndrome. FT3, FT4 and TSH levels were measured in all patients on admission. Patients were divided into STEMI, NSTEMI and UAP groups. Patient records were checked at 3 and 6 months of discharge in terms of sudden cardiac death and major cardiovascular events. The relationship between thyroid hormone levels and acute cardiac death and major cardiovascular disorders at 3 and 6 months of discharge was evaluated.

Results The mean TSH, FT3 and FT4 levels of the study group versus control group were as follows: TSH levels of study group 1.87 ± 1.73 μIU/ml, FT3 3.2 ± 1.34 pg/ml, FT4 1.45 ± 0.64 ng/dl. Abnormalities in the thyroid function tests were noted in 26 patients (23.6%). Of these seven patients (6.36%) had subclinical hypothyroidism, two patients (1.8%) had euthyroid sick syndrome and 10 patients (9%) had high serum FT4 levels despite normal FT3 and TSH values.

Conclusions We noted subclinical hypothyroidism, less frequently euthyroid sick syndrome and hyperthyroidism. No relationship was noted between thyroid hormone levels and sudden cardiac death and major cardiovascular disorders at 3 and 6 months follow-up. However, studies including larger patient groups are needed to clarify if there is a relationship between thyroid hormone levels on admission and sudden death and major cardiovascular events in patients with acute coronary syndrome.

Effect of reperfusion therapy on QTd and QTcd in patients with acute STEMI
D Ragab, F Elghawaby, M Eldesouky, T Elsayed
Cairo University, Cairo, Egypt

Introduction Acute ischemia alters action potentials and affects myocardial repolarization. Dispersion of repolarization is arrhythmogenic. QT dispersion has been suggested to give information about the heterogeneity of myocardial repolarization.

Methods Our study included 60 patients presented with acute STEMI, the study populations were divided into two groups: Group I: 30 patients who underwent primary PCI. Group II: 15 patients who received streptokinase. Group III: 15 patients who did not receive reperfusion therapy. QTd and QTcd were measured and compared in the three groups on admission, after 24 hours and after 5 days.

Results QTd and QTcd were significantly higher in patients with anterior compared with inferior MI (79.16 ± 25.67 ms vs. 62 ± 18.17 ms, P = 0.004 regarding QTd and 91.95 ± 28.76 ms vs. 68.33 ± 23.52 ms, P < 0.001 regarding QTcd). After 24 hours, QTd and QTcd were significantly lower in group I than groups II and III (34.33 ± 13.56 ms vs. 48 ± 18.2 ms vs. 66 ± 24.43 ms respectively, P < 0.05 as regards QTd and 39.33 ± 11.72 ms vs. 56 ± 23.84 ms vs. 74.60 ± 26.7 ms respectively, P < 0.05 as regards QTcd). On the 5th day reduction in QTd and QTcd was statistically significantly lower in group I than groups II and III (23 ± 9.52 ms vs. 45.33 ± 15.97 ms vs. 58.66 ± 23.25 ms respectively, P < 0.05 for QTd and 26 ± 11.63 ms vs. 52.66 ± 21.2 ms vs. 60.66 ± 23.25 ms respectively, P < 0.05 for QTcd). QT and QTcd on admission were higher in patients who developed ventricular arrhythmias than patients who did not (90 ± 11.55 ms vs. 70 ± 25.45 ms; P = 0.05 regarding QTd and 110 ± 8.61 ms vs. 80.53 ± 28.78 ms with P = 0.028 regarding QTcd). Patients with early peaking of enzymes had more reduction in QTd and QTcd early after reperfusion (43.2 ± 11.44 ms vs. 60.5 ± 13.16 ms, P < 0.001 regarding QTd and 49.60 ± 15.93 ms vs. 68.5 ± 17.55 ms, P < 0.001 regarding QTcd).

Conclusions QTd is higher in patients with acute MI (AMI) who developed ventricular arrhythmias. So QTd and QTcd on admission may be a helpful parameter that can detect patients with AMI who are at risk for development of ventricular arrhythmias. Reperfusion therapy with primary PCI or thrombolytic agents reduces QTd and QTcd in patients with AMI; however QTd and QTcd are shorter with primary PCI compared with thrombolytic therapy.

P3
Biochemical studies of some diagnostic enzymes in myocardial infarction
M Samir, H Khaled Nagi, D Ragab, M Refaie
Cairo University, Cairo, Egypt

Introduction Myocardial infarction (MI) is a key component of the burden of cardiovascular disease (CVD). The main causal and treatable risk factors for MI include hypertension, hypercholesterolemia or dyslipidemia, diabetes mellitus, and smoking. Acute MI results in cellular necrosis with release of constituent proteins into the circulation. Measurement of specific enzymes has become an important clinical tool for the diagnosis and management of MI. The aim of this study was to demonstrate the role of arginase and adenosine deaminase (ADA) in patients suffering from MI, and in a group of patients with chronic renal failure (CRF) with cardiovascular diseases (CVD).

Methods In this prospective study including 90 consecutive subjects were included the MI group (GI) consisting of 30 patients with mean age = 51.7 admitted to critical care medicine (CCM) in Cairo University...
Hospital, Egypt. (GI) included 30 patients of the CRF with CVD group with mean age = 49.1 undergoing periodic hemodialysis three times per week, compared with 30 normal volunteers included as the control group.

Results The mean value of serum arginase enzyme activity in patients with CRF with CVD has mean value 32.43 ± 6.5 U/L, P < 0.05 compared with the control group. ADA in the control group was 20.1 ± 2.39 U/l. But in (GI) the mean value was 44.99 ± 9.4 U/L, indicating a highly significantly increase was observed as compared with the control group (P < 0.001). ADA may be considered good diagnostic enzymes in patients suffering from MI, and ADA for patients with CRF with CVD.

P4 Pharmacological CCR1 blockade limits infarct size and preserves cardiac function in a chronic model of myocardial ischemia/reperfusion

A Van de Sandt, S Zander, S Becher, R Ercan, C Quast, J Ohlig, T Lauer, T Rassaf, M Kelm, MW Merx

Department of Cardiology, Pulmonary Diseases and Vascular Medicine, University Hospital, Düsseldorf, Germany

Introduction This study sought to determine the chronic effects of pharmacological blockade of the chemokine receptor CCR1 via application of the potent, selective antagonist BX471 in a murine model of myocardial ischemia/reperfusion (I/R). CCR1 is a prominent receptor in mediating inflammatory leukocyte recruitment. The intense inflammatory response is considered to be a key component of cardiac remodelling. Thus, limiting the post-reperfusion inflammatory pattern seems to be a promising therapeutic approach in limiting reperfusion injury. Previously, we demonstrated that CCR1 mice exhibit attenuated infarct expansion and preserved LV function in a chronic model of myocardial no-reflow infarction due to an abrogated inflammatory response.

Methods C57/B6 mice underwent a 60-minute coronary occlusion in a closed-chest model of myocardial I/R. Mice were treated with the specific CCR1 antagonist, BX471 (50 mg/kg BW, s.c.), or placebo, for 96 hours at 8-hour intervals starting 15 minutes prior to reperfusion. At 21 days of reperfusion, cardiac function was assessed using a pressure-volume catheter (Millar) inserted in the left ventricle. Infarct size was analysed and cardiac content for collagen was elucidated.

Results Infarct size was significantly smaller in the BX471-treated group (placebo: 20.7 ± 2.8% vs. BX471: 11.6 ± 4.2%, P < 0.05; area at risk did not differ between the groups). At 21 days of reperfusion BX471-treated mice exhibited a tendency towards improved cardiac function. Significantly improved diastolic function was documented in BX471-treated mice (P <0.01). In histochemical analysis, collagen content was elevated in the hearts of BX471-treated mice.

Conclusions Pharmacological CCR1 antagonism leads to improved diastolic function and attenuated infarct size in a chronic model of ischemia/reperfusion, suggesting that CCR1 antagonism might provide a promising therapeutic approach in myocardial infarction. The increased cardiac collagen documented in the treated group of our study might point towards a beneficial effect in the restructuring of the extracellular collagen matrix. Further studies of the underlying mechanisms and a detailed analysis of structural remodelling after pharmacological CCR1 blockade are warranted.

P6 Perioperative risk factors for serious gastrointestinal complications treated by laparotomy after cardiac surgery using cardiopulmonary bypass

P Soos1, B Schmack2, A Weymann1, G Veres1, B Merkely1, M Karck2, G Szabó3

1Semmelweis University, Budapest, Hungary; 2University of Heidelberg, Germany

Introduction Gastrointestinal (GI) complications are rare but often fatal consequences of cardiac surgery, especially after cardiopulmonary bypass (CPB) operations. The therapy can be conservative or – in critical cases – surgical; however, an early and safe diagnosis may prevent the development of life-threatening GI complications. The aim of our study was to characterize the risk factors and perioperative predictors for GI complications treated by laparotomy after CPB operations.

Methods In a retrospective analysis of 12 years of CPB operations, 13,555 consecutive patients were involved in the study. Laparotomy was performed after CPB in 277 (2.01%) cases, the mean follow-up time was 63.9 months.

Results Logistic regression analysis of the preoperative data demonstrated RR = 1.585 (OR: 1.340 to 1.876, P < 0.001) for heart failure according to the NYHA classification. The postoperative data analysis showed an RR = 12.257 (OR: 9.604 to 15.643, P < 0.001) for the need of an IABP implantation and an RR = 13.455 (OR: 10.516 to 17.215, P < 0.001) of low output syndrome in the GI complications group. In contrast, GI disease in the patient history seemed not to be a significant risk factor. Preoperative renal failure had an RR = 2.181 (OR: 1.686 to 2.821, P < 0.001) until postoperative renal failure had an RR = 29.145 (OR: 21.322 to 39.839, P < 0.001).

Conclusions A failing heart may play a significant role in critical GI complications after CPB, whereas history of GI disease does not seem to determine its incidence.

P7 Endotoxemia related to cardiopulmonary bypass is associated with increased risk of infection after cardiac surgery

DJ Klein, F Briet, R Nisenbaum, A Romaschin, C Mazer

St Michael’s Hospital, Toronto, Canada

Introduction The purpose of this study was to examine the prevalence of endotoxemia-supported aortic coronary bypass grafting surgery (ACB), using the endotoxin activity assay (EAA), and to explore the association between endotoxemia and postoperative infection.

Methods The study was a single-center prospective observational study measuring EAA during the perioperative period for elective ACB. Blood samples were drawn at induction of anesthesia (T1), immediately prior to release of the aortic cross-clamp (T2), and on
the first postoperative morning (T3). The primary outcome was the prevalence of endotoxia. The secondary outcome was rate of postoperative infection. An EAA of <0.40 was interpreted as low, 0.41 to 0.59 as intermediate, and >0.60 as high.

Results Fifty-seven patients were enrolled and 54 patients were analyzable. The mean EAA at T1 was 0.38 ± 0.14, at T2 0.39 ± 0.18, and at T3 0.33 ± 0.18. At T2 only 13.5% of patients had an EAA in the high range. There was a positive correlation between EAA and the duration of cross-clamp (P = 0.02). Eight patients developed postoperative infections (14.6%). EAA at T2 was strongly correlated with the risk of postoperative infection (P = 0.02) as was the maximum EAA over the first 24 hours (P = 0.02). See Figure 1.

Conclusions High levels of endotoxin occurred less frequently during ACB than previously documented. However, endotoxiaemia is associated with a significantly increased risk of the development of postoperative infection – a complication associated with an over doubling of risk of death. Measuring endotoxin levels may provide a mechanism to identify and target a high-risk population.

P8 Manual hyperinflation attenuates reduction of functional residual capacity in cardiac surgical patients: a randomized controlled trial
F Paulus, DP Veelo, SB De Nijs, P Bresser, BA De Mol, LF Beenen, JM Binnekade, MJ Schultz
Academic Medical Center, Amsterdam, the Netherlands

Introduction Cardiac surgical patients show deterioration of functional residual capacity (FRC) after surgery. Manual hyperinflation (MH) aims at preventing airway plugging, and as such could prevent the reduction of FRC after surgery. The purpose of this study was to determine the effect of MH on FRC in cardiac surgical patients.

Methods This was a randomized controlled trial of patients after elective coronary artery bypass graft and/or valve surgery admitted to the ICU of a university hospital. Patients were randomly allocated to routine MH strategy (MH within 30 minutes after arrival in the ICU and every 6 hours until tracheal extubation) or on-demand MH (MH only in cases of perceptible (audible) sputum in the larger airways or in case of a drop in SpO2 during mechanical ventilation. The primary endpoint was the change of FRC from the day before cardiac surgery to 1, 3, and 5 days after tracheal extubation. Secondary endpoints were SpO2 on the same time points, and chest radiograph abnormalities at day 3.

Results One hundred patients were enrolled. In the routine MH group FRC decreased to 72% of the preoperative measurement, versus 59% in the on-demand MH group (P = 0.002). Differences in FRC were not longer statistically significant at day 5 (Figure 1). There were no differences in SpO2 between the two groups. Chest radiographs showed more abnormalities in the on-demand MH group compared with patients in the routine MH group (P = 0.002).

Conclusions MH attenuates the reduction of FRC in the first three postoperative days after cardiac surgery.

P9 Incidence of cerebral desaturation events in the ICU following cardiac surgery
S Greenberg, A Garcia, L Howard, R Fasanella, J Vender
North Shore University Health System, Evanston, IL, USA

Introduction We hypothesize that there is a high incidence of cerebral desaturation events (CDE – an absolute decrease in SctO2 to <55% for ≥15 seconds) during the first 6 hours of ICU admission following cardiac surgery. Clinical trials have validated transcranial cerebral oximetry, a non-invasive tool that uses near-infrared spectroscopy to measure cerebral oxygen saturation, as a way to detect cerebral ischemia [1]. Cerebral oximetry is frequently used in the intraoperative setting, but rarely utilized postoperatively [2]. We attempted to identify if CDEs occur in the ICU.

Methods This IRB-approved, prospective, observational study captures the CDE incidence from 40 ASA IV patients in the ICU period following elective cardiac surgery. Exclusion criteria were: age <18, patients presenting for emergency surgery, and patients undergoing off-pump procedures. The FORE-SIGHT (CAS Medical Systems Inc., Branford, CT, USA) absolute cerebral oximeter monitor remained on patients for the first 6 hours in the ICU. All patients were managed according to the usual ICU standard of care. All care providers were blinded to CDEs during the 6-hour study period. During this time, a portable computer was attached to the cerebral oximeter, bedside physiologic monitor and mechanical ventilator, which recorded all data at 1-minute intervals and allowed data to be stored on a computer database.

Results Complete data were collected on 40 high-risk patients (mean age of patients = 71 (36 to 86), mean duration of intubation (hours) = 22.8 (6 to 240), mean duration of ICU stay (days) = 3.3 (1 to 20)). A majority of the patients underwent coronary bypass grafting only or valve only procedures. A high incidence, 13/40 (32.5%), of CDEs was observed in our study cohort, with some episodes exceeding 2 hours. A higher incidence of postoperative nausea/vomiting (PONV) was observed in patients with CDEs (3/13 vs. 0/27).
Conclusions This observational trial is the first to demonstrate a high incidence of CDEs in the immediate postoperative period (32.5%) among cardiac surgical patients. Our ongoing observational study will attempt to demonstrate correlations between physiologic parameters and these postoperative CDEs.

A nonrandomized comparison of off-pump versus on-pump coronary bypass surgery in Egyptian patients
H El-Abd1, S Salah2
1 Cairo University Hospitals, Cairo, Egypt; 2 Police Authority Hospital, Cairo, Egypt

Introduction Coronary artery bypass grafting (CABG) has traditionally been performed with the use of cardiopulmonary bypass (ONCAB). CABG without cardiopulmonary bypass (OPCAB) might reduce the number of complications. Thus, this study aims to compare between on-pump and off-pump surgery concerning postoperative morbidity and mortality, also to evaluate 6-month graft patency in Egyptian patients.

Methods This is a nonrandomized single-centre control trial prospectively conducted on 65 patients who were subjected to coronary artery bypass surgery followed by stay in the Open Heart Intensive Care Center of the Police Authority Hospital, in the period from July 2009 to January 2010. Patients were divided into two groups; group A: 25 patients underwent ONCAP, and group B: 40 patients underwent OPCAB. All of the demographic, operative and postoperative data were prospectively collected and analyzed statistically. Six months later, the patients underwent coronary angiography.

Results There was no significant difference between both groups intraoperatively concerning arrhythmias, blood transfusion, and hemodynamic support. Off-pump patients had a significantly higher mean number of constructed grafts than in the ONCAP group (mean, 3.30 ± 0.88 vs. 2.84 ± 0.80; P = 0.02). There were no significant differences between off-pump and on-pump regarding postoperative blood loss, blood transfusion, length of the ICU and the hospital stay, the ventilation time, the use of IABP, renal complications, respiratory complications, and reopening. However, graft occlusion, MI, ventricular tachycardia, cardiogenic shock, and disturbed conscious level significantly occurred in the OPCAB group. Postoperative mortality rate was significantly higher in the OPCAB group than in the ONCAP group (15% vs. 0%; P = 0.046). Follow-up angiograms in 40 patients (61.5%) who underwent 124 grafts revealed no significant difference between off-pump and on-pump groups regarding overall rate of graft patency (83.5% vs. 84.4%; P = 0.84). No mortality was reported in both groups at 6-month follow-up.

Conclusions There was a higher incidence in postoperative complications and mortality in off-pump procedure than the on-pump. At 6-month follow-up, no significant differences between both techniques were found in graft patency and mortality.

Extracorporeal membrane oxygenation for cardiopulmonary support after open heart surgery
UJ Jaschinski, G Kierschke, H Forst, M Beyer
Klinikum Augsburg, Germany

Introduction Arterial–venous extracorporeal membrane oxygenation (ECMO) is a rescue tool in acute heart failure after cardiopulmonary bypass (CPB) when separation from CPB cannot be achieved by conventional means (volume, inotropes, intra-aortic counterpulsation IABP). The role of ECMO in this scenario is far from clear and factors predicting a poor outcome are lacking. However, such indices would be helpful to find a reasonable approach.

Methods Analysis of a prospective evaluated dataset in a surgical ICU of a university teaching hospital.

Results In 19 patients (mean age 58 years) with postcardiotomy cardiogenic shock despite high-dose medication with inotropes and normal filling pressures, separation from CPB was not possible. These patients were scheduled for ECMO. The mean preoperative EF was 20.8% and in 47.3% of the patients cardiopulmonary resuscitation (CPR) had to be performed already before CPB. Eleven patients (57.8%) received an IABP before ECMO. The most frequent complications in the ICU were: arrhythmia (63.1%), bleeding (78.9%), renal failure with CRRT (47.3%) and respiratory failure (paO2/FiO2 <250 mmHg) (100%). The mean duration on ECMO was 6.8 days, mean stay in the ICU was 13.1 days and mean hospital stay was 44.5 days. Only 6/19 patients survived (31.5%) and were discharged from hospital. These patients except one had no CPR in the preoperative period.

Conclusions ECMO in acute heart failure after adult open heart surgery in this series had an enormous high mortality of 68.5%. However, these results are in line with other series with a reported mortality of 67 to 75.2% [1,2]. CPR in the preoperative setting seems to be a grave sign for survival and in these patients ECMO is not recommended since mortality reaches an unacceptable high rate. This statement needs to be confirmed by an adequate powered trial.

Quality of life after cardiac surgery in an octogenarian population
MNydegger, ABoltres, K Graves, A Zollinger, CKHafer
Triemli City Hospital, Zurich, Switzerland

Introduction An increasing number of cardiac surgery procedures are performed today in patients >80 years [1]. However, only limited data are available regarding the postoperative outcome in this patient group. The aim of this study was to assess quality of life in patients >80 years after elective cardiac surgery (CS80) compared with younger patients (60 to 70 years; CS60).

Methods Consecutive CS80/CS60 patients during a 1-year period were contacted 12 months after cardiac surgery. A structured interview was performed and quality of life was assessed (SF-36 health survey). Norm-based scoring (transformed to mean = 50 ± 10) was analysed. Sociodemographic and procedure-related data were obtained from the hospital database. Student’s t-test and the chi-square test were used to compare both groups.

Results Fifty-three and 52 datasets for CS80 and CS60, respectively, were available for statistical analysis: mean age was 82.2 ± 2.7 years (CS80) and 64.7 ± 2.7 years (CS60, P <0.001). There was no significant difference of preoperative cardiac function or risk score (ejection Figure 1 (abstract P12). Norm-based SF-36 scoring profile: (a) single components and (b) component summaries.
fraction: CS80: 54 ± 14%, CS60: 54 ± 13%; P = 0.78. Euroscore: CS80: 9.3 ± 0.24, CS60: 6.9 ± 3.7, P = 0.09. ICU length of stay was 53 ± 9.1 days (CS80) and 2.6 ± 2.7 days (CS60, P = 0.04); hospital length of stay was 15.6 ± 10.1 days (CS80) and 15.1 ± 8.5 days (CS60, P = 0.79). The 30-day mortality rate was 11.5% (CS80) and 5.6% (CS60, P = 0.27), and 1-year mortality was 16.3% (CS80) and 7.6% (CS60, P = 0.13). SF-36 physical and mental health components ranged from 44.8 ± 10.8 to 54.2 ± 7.6 (CS80) and from 48.7 ± 13.5 to 52.7 ± 7.9 (CS60, Figure 1); physical function (PF) was significantly lower for CS80 (P = 0.002). Physical component summary (PCS) was 45.6 ± 0.9 (CS80) and 51.3 ± 8.8 (CS60, P = 0.03); mental component summary (MCS) was 54.7 ± 7.9 (CS80) and 50.8 ± 12.0 (CS60; P = 0.75; Figure 1).

Conclusions Quality of physical health with only minor limitations was observed in patients after cardiac surgery aged >80 years as compared with younger patients (60 to 70 years). There was no difference of mental health quality between both patient groups. These results could only be achieved with increased ICU length of stay for patients >80 years.

Levels of serum B12, folinic acid and homocysteine in thromboembolic diseases on admission to the Emergency Department
A Bayer1; K Uçar Karabulut1; A Ak2
1Selçuk University, Selçuklu Faculty of Medicine, Emergency Department, Konya, Turkey; 2Şirnak State Hospital, Şirnak, Turkey

Introduction The aim of this study was to compare with control and examine the levels of serum B12, folinic acid and homocysteine at admission in the cases with thromboembolic diseases.

Methods This study included 100 subjects with acute myocardial infarctus (AMI), acute pulmonary embolism, deep vein thrombosis, ischemic cerebrovascular disease (ICD), acute mesentery embolism, and peripheral artery embolism (PAE), and 110 healthy voluntary subjects were included in the control group. Vitamin B12, folinic acid and homocysteine levels were examined in the blood samples obtained at admission. The data were loaded onto SPSS 16 for Windows program. P ≤0.05 was considered significant.

Results Mean serum homocysteine and plasma vitamin B12 levels were significantly higher in the patient group than the control group (P = 0.002 and 0.000 respectively). There was no significant difference in the levels of folic acid between the patient and control groups. Mean serum B12 values of the AMI and ICD groups in the patient group were significantly lower than those of the control group (P <0.05). Serum folinic acid values of the PAE and AMI groups were considerably lower than the control group (P <0.05). Plasma homocysteine levels were significantly higher in all patient groups according to their diagnosis than the control group (P <0.05).

Conclusions Mean serum homocysteine and plasma vitamin B12 levels were significantly higher in the patient group than the control group (P = 0.002 and 0.000 respectively). There was no significant difference in the levels of folic acid between the patient and control groups. Mean serum B12 values of the AMI and ICD groups in the patient group were significantly lower than those of the control group (P <0.05). Serum folinic acid values of the PAE and AMI groups were considerably lower than the control group (P <0.05). Plasma homocysteine levels were significantly higher in all patient groups according to their diagnosis than the control group (P <0.05).

Deep venous thrombosis Doppler screening in critically ill patients: is it justified?

Vlachou1, G Petroucheiou1, E Evodia2, M Pappa1, L Livieratos1, P Myriantarlis1, L Gregorkakis2, G Baltopoulos1
1St Paul Hospital, Athens, Greece; 2Agioi Anargyroi Hospital, Athens, Greece

Introduction The purpose of this study was to determine the incidence of asymptomatic deep venous thrombosis (DVT) in long-stay critically ill patients.

Methods Over an 8-month period, 53 patients were admitted and anticipated to stay in the ICU for >48 hours. DVT prophylaxis was provided using low molecular weight heparin (LMWH) or a sequential compression device. The DVT prophylaxis was evaluated using low molecular weight heparin (LMWH) or a sequential compression device. The diagnosis of DVT was confirmed with duplex ultrasound screening of the symptomatic limb. All patients were screened for DVT prophylaxis on admission and every 7 days. The data were collected on a weekly basis regardless of clinical or laboratory evidence for DVT. Demographics and ultrasound data were also collected.

Results We studied 53 patients (42 males, mean age (SEM) 57.6 ± 2.8 years, illness severity scores APACHE II 21.3 (9.9); SAPS II 53.3 (2.3); SOFA 10.2 (0.2); and ICU stay 35.9 (4.8) days). Eleven (20.8%) of them developed DVT on day 7.4 (1.8), on DUS. Six patients had lower limb DVT, five upper limb DVT. Another one had DVT on admission. In group A (Table 1), six patients (37.5%) developed DVT on day 7.0 (2.4) without receiving LMWH due to underlying disease (hormorrhagic stroke, brain injury), but only pneumatic compression. In group B (Table 1), five patients (13.5%) developed DVT on day 7.7 (2.9) despite timely and appropriate LMWH administration since ICU admission.
None of the patients in both groups developed pulmonary embolism. The difference regarding the incidence between the two groups was statistically significant ($P = 0.042$, RR: 2.847 [CI: 1.050 to 7.721], OR: 4.167 [CI: 0.989 to 17.55]).

Conclusions According to our results the application of DUS screening in ICU patients seems to be justified for early, accurate diagnosis of silent DVT and appropriate therapy.

P16
Pulmonary embolism in the ICU: clinical and prognostic signification – can we predict mortality?
A Aller, M Mourelo, P Vidal
University Hospital A Coruña, Spain

Introduction This study was to define characteristics of patients with pulmonary embolism (PE) admitted to the ICU, and to determine the usefulness of predictive models of empirical prognostic stratification.

Methods Retrospective study of patients who developed PE during the ICU stay or were admitted to the ICU for PE for 5 years (2005 to 2010). We analyzed: age, sex, history, diagnosis, complications and mortality. Univariate analysis using Student t and chi-square tests, and multivariate using logistic regression.

Results We found 64 patients. Mean age was 64 years (SD 16.2); 51.6% were women, 18.8% had a neoplasia, 65.5% were admitted for PE from the emergency room. The rest were: medical (18.8%), surgical (7.8%) or traumatic (6.3%). In total, 79.7% dyspnea, 34.4% chest pain, 14.1% cardiorespiratory arrest. The diagnosis was mainly by CT (71.4%), echocardiography (15.9%) and clinical (12.7%). Of patients, 92.1% had higher D-dimer, 33.3% had elevated troponin I; 66.7% had right ventricular dysfunction (RVD), 86.1% had pulmonary arterial hypertension (PAH); 57.8% metabolic acidosis; 42.2% hemodynamic instability; 44.4% catecholamines, 50% volume administration, 30% developed ARDS. Of the patients, 31.3% received systemic thrombolysis, 3.1% endovascular treatment. In 4.7% a vena cava filter was placed. In univariate analysis with regard to mortality we find significant: ARDS ($P < 0.000$, catecholamines ($P = 0.000$, acidosis ($P = 0.010$, hemodynamic instability ($P = 0.002$), in multivariate analysis: predictor of mortality SAPS II scale ($P = 0.04$, OR 0.06 [CI 0.99 to 1.12]), ROC curves for scales (Geneva, Wells, PESI), finding an area of 0.55, 0.65, 0.47, respectively. In a univariate analysis with regard to PESI III to V, we found significant: SAPS II ($P = 0.01$), age ($P = 0.005$, PAH ($P = 0.03$, volume ($P = 0.01$, catecholamines ($P = 0.000$, hemodynamic instability ($P = 0.000$). In the multivariate analysis: SAPS II ($P = 0.046$, OR 0.071 [CI 0.86 to 0.99]), In the univariate analysis with regard to fibrinolysis: SAPS II ($P = 0.000$, PESI ($P = 0.000$, hemodynamic instability ($P = 0.000$). The median stay in ICU was 4 days, ICU mortality was 14.1%.

Conclusions Diagnosis of PE is primarily radiological. The majority of patients requiring ICU admission have RVD. Tropinin has little sensitivity for the diagnosis of PE. Prognostic stratification scales do not seem to be reliable predictors of mortality; however, high PESI grades correlates with reduced mortality. Hemodynamic instability, metabolic acidosis and ARDS were independent predictors of mortality.

Model-based cardiovascular monitoring of acute pulmonary embolism in porcine trials
JRA Revie1, DJ Stevenson1, JG Chase1, CE Hann1, BC Lambermont1, A Ghysen2, P Kolth1, GM Shaw3, T Desai1
1University of Canterbury, Christchurch, New Zealand; 2University of Liege, Belgium; 3Christchurch Hospital, Christchurch, New Zealand

Introduction Diagnosis and treatment of cardiac and circulatory dysfunction can be error-prone and relies heavily on clinical intuition and experience. Model-based approaches utilising measurements available in the ICU can provide a clearer physiological picture of a patient’s cardiovascular status to assist medical staff with diagnosis and therapy decisions. This research tests a subject-specific cardiovascular system (CVS) modelling technique on measurements from a porcine model of acute pulmonary embolism (APE).

Methods Measurements were recorded in five pig trials, where autologous blood clots were inserted every 2 hours into the jugular vein to simulate pulmonary embolism. Of these measurements only a minimal set of clinically available or inferable data were used in the identification process (aortic and pulmonary artery pressure, stroke volume, heart rate, global end diastolic volume, and mitral valve closure times). The CVS model was fitted to 46 sets of data taken at 30-minute intervals ($t = 0, 30, 60, ..., 270$) during the induction of APE to identify physiological model parameters and their change over time in APE. Model parameters and outputs were compared with experimentally derived metrics and measurements not used in the identification method to validate the accuracy of the model and assess its diagnostic capability.

Results Modelled mean ventricular volumes and maximum ventricular pressures matched measured values with median absolute errors of 4.3% and 4.4%, which are less than experimental measurement noise (~10%). An increase in pulmonary vascular resistance, the main hemodynamic consequence of APE, was identified in all the pigs and related well to experimental values ($R = 0.68$). Detrimental changes in reflex responses, such as decreased right ventricular contractility, were noticed in two pigs that died during the trial, diagnosing the loss of autonomous control. Increases in the ratio of the modelled right to left ventricular end diastolic volumes, signifying the leftward shift of the intraventricular septum seen in APE, compared well with the clinically measured index ($R = 0.88$).

Conclusions Subject-specific CVS models can accurately and continuously diagnose and track acute disease-dependent cardiovascular changes resulting from APE using readily available measurements. Human trials are underway to clinically validate these animal trial results.

P18
Pulmonary embolism diagnostics from the driver function
DJ Stevenson1, J Revie1, JG Chase1, CE Hann1, A Le Compte1, GM Shaw2, B Lambermont1, P Kolth1, T Desai1
1University of Canterbury, Christchurch, New Zealand; 2Christchurch Hospital, Christchurch, New Zealand

Introduction Ventricular driver functions are not readily measured in the ICU, but can clearly indicate the development of pulmonary embolism (PE) otherwise difficult to diagnose. Recent work has developed accurate methods of measuring these driver functions from readily available ICU measurements. This research tests those methods by assessing the ability of these driver functions to diagnose the evolution of PE.

Methods PE was induced in five pigs with cardiac measurements taken every 30 minutes. Pig-specific driver functions are estimated at each time point from aortic artery pressure waveforms. Increases over time in two validated model-based metrics indicate PE: pulmonary artery resistance (R pulmonary) and the Right Ventricle Expansion Index (RVEI). R Pulmonary and RVEI at each time point were paired to specific points on the right driver function that change as PE is induced. The significant points of interest are: (1) left-shoulder (LS) of the right driver function

P20 Deep venous thrombosis in ICU patients: exploring the submerged part of the iceberg by an expanded intra-ICU ultrasound surveillance program
A Cuccii, M Boddi, M Ciappeti, F Barbani, M Bonizzoli, J Parodo, L Perretta, G Zagli, E Spinelli, A Peris
Careggi Teaching Hospital, Florence, Italy

Introduction Deep venous thrombosis (DVT) of lower extremities is a well-known complication in critically ill patients, but data for DVT prevalence in upper venous districts are rare. To explore the real prevalence of DVT in ICU patients, intensivists’ routine ultrasound (US) surveillance was extended to include upper vein districts.

Methods This before-and-after intervention study included patients admitted to our ICU of a tertiary referral center for trauma and ECMO assistance (Careggi Teaching Hospital, Florence, Italy). The level I vascular US consists of evaluation of the lumen, and complete compressibility of the vein compression: it is performed by the intensivist on duty within the first 24 hours after ICU admission, every 7 days of the ICU stay or in cases of suspected DVT. A level II US examination is performed by a vascular specialist as a second opinion in cases of unclear or positive level I examinations. In 2010, the DVT surveillance protocol was extended to assess from lower extremities to include also the proximal upper extremities (axillary, brachial, cephalic veins) and internal jugular veins. DVTs already present at ICU admission were not included in the study, as well as central venous catheter (CVC)-related thrombosis less than 3 mm of thickness.

Results In 2009, 436 patients were admitted to our ICU (male sex 44%, mean age 57 years, mean SAPS II 36.6). Among the 436 patients admitted, a total of 466 level I examinations: eight cases of lower extremities DVT were diagnosed (1.8% of patients admitted) at level I examination. After introduction of expanding level I US surveillance (January to October 2010), 321 patients were admitted to our ICU (male sex 64%, mean age 55 years, mean SAPS II 37.6). A total of 358 level I examinations were performed. Expanding surveillance to upper venous districts, a significantly higher DVT rate (25 cases, 7.8%; P < 0.001) at level I examination was found, all confirmed by the level II examination. In details, lower extremities DVTs were nine (2.8%), upper extremities DVTs 16 (5%), 11 of which were CVC-related at internal jugular vein. Mean time between admission and DVT diagnosis was 9.1 days.

Conclusions The lower extremities DVT represent only the tip of the DVT iceberg in critically ill patients. Our results suggest that routine intra-ICU US surveillance should include all venous districts, with particular care of those in which intravascular devices are positioned.

P21 Antiembolic stockings and pneumatic compression devices in a medical–surgical thrombophrophylaxis trial
N Zytaruk, D Heels-Ansdell, S Vallance, J Marshall, Y Skrobik, DJ Cooper, S Finfer, I Seppelt, M Ostermann, I Qushmaq, MA Al-Ali, YA Arab, IA Alhassan, MA Al-Hazmi, A Alzem, N Shakh, M Yendou, DJ Cook
1McMaster University, Hamilton, Canada; 2Alfred Hospital, Melbourne, Australia; 3St Michael’s Hospital, Toronto, Canada; 4Maisonneuve Rosemont, Montreal, Canada; 5The George Institute, Sydney, Australia; 6Nepean Hospital, Sydney, Australia; 7Guy’s & St Thomas’ Hospital, London, UK; 8King Faisal Hospital, Jeddah, Saudi Arabia; 9King Abdulaziz Hospital, Riyadh, Saudi Arabia; 10King Abdulaziz Hospital, Jeddah, Saudi Arabia; 11King Fahad Hospital, Riyadh, Saudi Arabia; 12Riyadh Military Hospital, Riyadh, Saudi Arabia

Introduction A recent randomized trial (CLOTS-1) has called into question the utility of antiembolic stockings (AESs); another trial (CLOTS-2) suggested harm with below-knee compared with above-knee AESs. AESs and pneumatic compression devices (PCDs) could represent important co-interventions in a heparin thromboprophylaxis trial if exposure was lengthy and frequent. Our objective was to document the use of AESs and PCDs applied per protocol and by

(correrated with the dead-space volume); (2) maximum pressure gradient (MPG) of the right driver function (related to compliance); and (3) the total area (TA) of the right driver function (analogous to work done by the ventricle). Correlations are calculated for each pig, and for measurements and driver functions averaged across all five pigs to see a general trend.

Results Pig-specific correlations were median (range): (1) RVEI to LS: 0.56 (range: 0.3 to 0.99); (2) RVEI to MPG: 0.59 (range: 0.25 to 0.99); and (3) Rpul to TA: 0.53 (range: 0.04 to 0.85). Correlation levels were not consistent across pigs or metrics with the maximum for each pig across the three metrics of (0.98, 0.95, 0.56, 0.54, 0.59), indicating inter-pig variability in the experimental response to PE and its impact on the identified driver functions. Averaging the data and driver functions over the five-pig cohort yielded excellent correlations between Rpul, RVEI and the estimated right driver function of: (1) RVEI to LS: R = 0.96; and (2) Rpul to TA: R = 0.96. These results show the potential diagnostic capability of this approach in this limited animal trial.

Conclusions This research suggests that PE can be diagnosed and tracked from knowledge of a model-based driver function developed from readily available ICU measurements. Further animal and human investigations are required to confirm these results.

P19 Pulmonary embolism in medical–surgical ICU patients
D Heels-Ansdell, N Zytaruk, M Meade, S Mehta, R Zarychanski, M Rocha, L Liu, F Lamontagne, L McIntyre, D Heels-Ansdell, S Vallance, A Davies, P Reed, D Heels-Ansdell, D Cook
1McMaster University, Hamilton, Canada; 2Mount Sinai Hospital, Toronto, Canada; 3Capital Health – QEII, Halifax, Canada; 4Cancer Care Manitoba, Winnipeg, Canada; 5Sherbrooke Hospital, Quebec, Canada; 6Ottawa Health Research Institute, Ottawa, Canada; 7St Paul’s Hospital, Vancouver, Canada; 8Alfred Hospital, Melbourne, Australia

Introduction Pulmonary embolism (PE) is a feared complication of critical illness. PE is difficult to diagnose during critical illness due to the nonspecificity of signs and symptoms and low index of suspicion in practice. Our objective was to examine the antecedent characteristics and hospital course of patients who were diagnosed with PE during critical illness in the context of an international trial of thromboprophylaxis (NCT00182143).

Methods Research coordinators documented all clinical, laboratory, radiologic and autopsy criteria relevant to PE, which was a secondary outcome for this multicenter trial. Patients with a possible PE were adjudicated in quadruplicate; those considered possible, probable or definite PE were considered in this analysis. PEs were considered clinically suspected if the ICU team conducted tests seeking a diagnosis; otherwise, they were incidental.

Results In 3,659 patients, PE was clinically suspected in most patients who were diagnosed with a prevalent PE at ICU admission (12/14, 85.7%) or incident over the course of the ICU stay (57/64, 89.1%). Among 64 patients who developed a PE, only three (4.7%) had prehospital DVT or PE. Within the index hospitalization, before or after the PE diagnosis, additional acute deep venous thromboses occurred at any site in 27 (42.2%) patients with PE. Patients without PE compared with those with PE appeared to have a shorter duration of ventilation (median, interquartile range) (5 (2, 11) days vs. 12 days (5.5, 20.5), P < 0.001), duration of ICU stay (9 (6, 16) days vs. 20.5 (13, 35), P < 0.001), and hospital stay (21 (13, 40) days vs. 35 (21.5, 58.5), P < 0.001), duration of ICU stay (9 (6, 16) days vs. 20.5 (13, 35), P < 0.001), and hospital stay (21 (13, 40) days vs. 35 (21.5, 58.5), P < 0.001), and a lower ICU mortality (15.2% vs. 31.8%, P = 0.005) and hospital mortality (22.8% vs. 31.3%, P = 0.13).

Conclusions The majority of PEs in these medical–surgical ICU patients were clinically suspected rather than incidental findings. More than one-half of the PEs developed in the absence of leg or other venous thromboses; in some cases, additional venous thromboses post-dated rather than pre-dated the PE. PE was associated with significantly increased morbidity and mortality in this ICU population.

protocol violation in a trial comparing UFH versus LMWH in medical–surgical ICU patients (NCT00182143).

Methods A total of 3,659 patients were recruited internationally. The blinded study drug was administered daily in the ICU. Mechanical prophylaxis was only protocolized for use if anticoagulant prophylaxis was contraindicated (major bleeding, high risk for major bleeding, or suspected or proven heparin-associated thrombocytopenia). Research coordinators prospectively documented daily exposure to study drugs and mechanical prophylaxis.

Results A total of 3,659 patients were enrolled for a median (IQR) ICU stay of 9 (5, 16) days. AEs were used per protocol in 17.1% of patients for 1 (1, 1) day; 14.1% of the patients had knee-length stockings. AES used in violation of the protocol occurred in only 2.6% of patients (1.9% of the patients had knee-length stockings), for which the duration of exposure was 1.5 (1, 4) days. PCDs were used per protocol in 11% of patients for 1 (1, 3) days, and in 1.8% of patients for 2 (1, 3) days in violation of protocol.

Conclusions In keeping with uncertain effectiveness of mechanical thromboprophylaxis, and emerging evidence about harm with knee-length stockings, the co-intervention of mechanical thromboprophylaxis on the results of the PROTECT testing anticoagulant thromboprophylaxis trial will be minimal. AES and PCD use was brief, and largely reserved for days when heparin was contraindicated, as per clinical practice.

Upper extremity thromboses in medical–surgical critically ill patients

N Zytkow1, F Lamontagne1, P Dodek1, N Vlahakis5, B Lewis5, P22

Introduction Venous thrombosis of the upper extremity is a recognized complication of critical illness. The objective of this study was to describe the incidence and characteristics of upper-extremity thromboses in patients who were enrolled in an international trial that compared UFH versus LMWH as prophylaxis for VTE (NCT00182143).

Methods We recorded the location, extent and prior catheterization of all patients who had upper-extremity venous thromboses confirmed by compression ultrasonography or computed tomography. No patients were routinely screened for upper-extremity thromboses. We excluded prevalent thromboses found within 72 hours of ICU admission. If a patient had both deep and superficial thromboses, we categorized as deep; if a patient had both proximal and distal thromboses, we categorized as proximal. We defined catheter-related thromboses as partial or complete noncompressibility of the same or a contiguous segment in which a catheter had been inserted within the previous 72 hours. Events were adjudicated in duplicate by physicians blinded to study drug and each others’ assessments.

Results Among 3,659 patients, 72 (2.0%) developed upper extremity thrombosis involving 129 unique venous segments. Of 72 patients, 35 (48.6%) patients had thromboses in more than one segment. Most thromboses (86, 66.7%) were on the right side. Most of these were deep (56, 77.8%), but a few were superficial (16, 22.2%). Most had proximal thromboses (65, 90.3%), but a few had distal (7, 9.7%). The three commonest sites of thrombosis were the internal jugular (29.5%), subclavian (18.6%) and cephalic (17.8%) veins. Less commonly affected were the brachial (12.4%), axillary (8.5%), basilic (8.5%), innominate (3.9%) and external jugular (0.8%) veins. Overall, 69 (53.5%) thromboses were catheter-related.

Conclusions in medical–surgical patients who are receiving heparin prophylaxis, upper extremity DVT was uncommon, occurring in 2% of patients. These thromboses may be clinically important, because the majority is proximal and three-quarters are deep. Revisiting the need for central vascular access daily is underscored by the finding that half were catheter-related.

Real-time ultrasound guidance for internal jugular vein catheterization in neonates: preliminary experience

M Di Nardo, F Stoppa, C Tomasselli, C Cecchetti, M Marano, D Perrotta, E Pasotti, N Pirozzi

Introduction Recent studies reported that real-time ultrasound guidance for internal jugular vein catheterization is useful in infants. However, this technique is sometimes difficult even for skilled physicians. The aim of our study is therefore to evaluate the success rate and the complication rate of this technique performed by ultrasound-trained pediatric intensivists in neonates.

Methods Fifteen consecutive term neonates (mean weight 3.9 ± 1.1 kg) needing a central venous access for intensive care treatment were prospectively studied for ultrasound-guided internal jugular vein cannulation. Patients’ age, weight, time for cannulation, catheter size, central venous time permanence, success rate and complications rate were recorded.

Results Cannulation was successful in all 15 infants. The right internal jugular vein was used in 90% of the patients enrolled, while in the remaining 10% the left internal jugular vein was used. The overall complication rate was 22%. We had only one major complication (2%): lung pneumomotorax. Minor complications were: multiple skin and vein punctures (9%), Seldinger wire kinking (7%) and venous hematomas (4%). Time required for complete cannulation was 8 ± 4.3 minutes, while the mean duration of the central venous catheter was 5 ± 5 days.

Conclusions Our results suggest that ultrasound assistance for central vein cannulation can be easily performed by well-trained physicians in neonates. Particular solutions (increase of the tilting angle of the bed, use of soft nitonil tip guide wire and the transfixation technique) can be sometimes requested to increase the success rate of our procedures. In accordance to these considerations, US-guided CVC placement should be probably considered as the first choice method for catheterization in infants.

Is routine ultrasound examination of the gallbladder justified in ICU patients?

E Evodias1, I Vlachou1, G Petrelloioiu1, A Gavala1, M Pappas1, L Livieratos2, M Pappa1, L Livieratos2

Introduction Gallbladder (GB) abnormalities are frequently seen in critically ill ICU patients. The purpose of the study was to evaluate protocolized GB US examination in medical decision-making.

Methods In this prospective study a twice per week GB US examination was performed in critically ill patients under mechanical ventilation

http://ccforum.com/supplements/15/S1

Critical Care 2011, Volume 15 Suppl 1

S8
(MV) for a period of 8 months independently of liver biochemistry to identify GB abnormalities. Hepatic dysfunction was defined as bilirubin >2 mg/dl and/or alkaline phosphatase >200 IU/l [1]. US findings that were evaluated included: gallbladder wall thickening, gallbladder distention, striated gallbladder wall, pericholecystic fluid and gallbladder sludge. We also recorded associated clinical and laboratory parameters: fever, WBC, MV status, liver function and administration of parenteral nutrition, analgesics, pressor agents, and predisposing factors that were associated with high incidence of acute acalculous cholecystitis (AAC).

**Results** We included 53 consecutive patients (42 males, mean age 57.6 ± 2.8 years, illness severity scores APACHE II 21.3 ± 0.9; SAPS II 53.3 ± 2.3; SOFA 10.2 ± 0.2; and mean ICU stay 35.9 ± 4.8 days) of which 25 (47.2%) had at least one US findings. Sixteen patients (30.2%) had two or more US findings. Only six patients (24%) with ultrasound findings had also concomitant hepatic dysfunction while 19 (76%) with positive ultrasound findings did not have; difference statistically significant (c², P = 0.03). Of the remaining 19 patients, three patients had increased y-GT only (≥150 IU/l, 415.3 ± 50.2), and two patients had increased SGPT only (≥150 IU/l, 217.5 ± 31.2). Three patients had US findings compatible with AAC underwent open cholecystectomy. Only one of them had concomitant hepatic dysfunction, as defined. Patients experiencing two or more US findings and/or liver dysfunction but not ACC were medically managed including gastric drainage, modulation of antibiotic therapy and/or interruption of nutrition until resolution of US findings or improvement in laboratory findings. In nine patients with US findings without hepatic dysfunction or increased y-GT /SGPT, enteral or parenteral nutrition was stopped and were monitored, until improvement.

**Conclusions** Routine GB US examination was able to guide surgical therapy for AAC despite the absence of liver dysfunction. Also, it was useful to guide the medical therapy and the administration of nutrition during the ICU stay.

Transthoracic echocardiography performed by intensive care fellows: is minimal focused training enough?

M Almaani, M Alabdor Alnabi, D Bainbridge, R Taneja
University of Western Ontario, London, Canada

**Introduction** Transthoracic echocardiography (TTE) has an important role in the diagnosis of shock in the ICU. There is evidence that noncardiologist residents can address simple clinical questions in the ICU with TTE [1]. We conducted this study to evaluate whether ICU fellows, with minimal focused training in TTE, could reliably acquire good-quality images in critically ill patients.

**Methods** After research ethics board approval, 19 adult patients requiring echocardiography as per the attending physician were enrolled. Patients were enrolled if they were hemodynamically unstable and were adapted on the ventilator. Each patient underwent TTE by one of the certified echocardiographers and then subsequently by a blinded ICU fellow with minimal training in TTE (3-day ultrasound course, 7 hours hands-on training). All images were reviewed offline independently and graded [2] by two blinded reviewers. Interobserver agreement was measured using the intraclass correlation coefficient (ICC). Image quality was graded on a scale from 1 (excellent) to 4 (very poor) and the composite image score (total score out of a possible 20 for five views: parasternal short and long axis, apical, subcostal and IVC views) was compared between groups using the Wilcoxon paired test. Each patient’s images were further analysed to assess whether the images of LV, RV and IVC had been acquired.

**Results** Nine patients were diagnosed with cardiogenic, eight with distributive and two patients with hypovolemic shock at the time of enrollment in the study. A total of 169 images were analysed. The ICC for interobserver agreement was good (0.8). There was no statistical difference between the composite image scores acquired by ICU fellows (12.3 ± 0.7) (mean ± SE) in comparison with certified echocardiographers (11 ± 0.6, P = 0.08). However, the ICU fellows could not acquire images of the RV or LV in five out of 19 patients (26%) in comparison with corresponding images by certified echocardiographers.

**Conclusions** ICU fellows, with minimal focused training in TTE, can acquire images that are comparable in quality with certified echocardiographers in our institution. However, they are not able to acquire images of the LV or RV in over 25% patients as compared with certified echocardiographers. Minimal focused training in TTE may not be enough when managing critically ill patients.

Survey of echocardiography provision and practice in ICUs in the United Kingdom

A Cooke1, S Bruemmer-Smith1, J McLoughlin1, J McCaffrey1
1Belfast City Hospital, Belfast, UK; 2Brighton and Sussex University Hospital, Brighton, UK; 3Sir Charles Gardiner Hospital, Perth, Australia

**Introduction** Echocardiography in the intensive care unit (ITU) has been shown to be a valuable aid to clinical decision-making [1–3]. Currently, there is no formal training process for intensivists wishing to learn echocardiography in the United Kingdom, and there is little information on the current state of clinical practice.

**Methods** A structured questionnaire was sent to each intensive care unit in the United Kingdom. The questionnaire detailed information regarding the availability of echocardiography and the frequency that echocardiograms are performed in the ITU. We enquired after the level of training in echocardiography by intensivists, the reporting process and availability of currently provided training. Opinions on the necessity of formalised training and the level of that training were also sought.

**Results** Responses were obtained from 32 units ranging in size from five to 35 critical care beds. A total of 53.13% have their own dedicated echo machine. Only 15.6% have a transoesophageal probe. In 28% of ITUs echocardiograms are performed by intensivists; however, only 25% of ITUs currently offer echocardiography training to intensive care trainees. Seventy-eight per cent of respondents believed that ITU physicians should have at least intermediate echocardiography skills; 97% respondents believed that a national training programme should be established for echocardiography practice by ITU physicians.

**Conclusions** Echocardiography is currently widely used in ITUs throughout the United Kingdom but is often being performed by physicians with little or no formal training. There is almost unanimous support for a national structure and a formalised curriculum to achieve safe widespread training.

Clinical and economic impact of a TEE monitoring system in intensive care

HM Hastings, SL Roth

**Introduction** The purpose of this study was to determine the clinical and economic impact of hemodynamic monitoring in intensive care with the ImaCor TEE monitoring system, including a miniaturized, detachable, single-use probe (the ImaCor ClariTEE™). TEE has been cited as especially appropriate for hemodynamic monitoring because abnormalities are multifactorial; or example, hypovolemia, LV and RV dysfunction, tamponade. Unlike conventional probes, the ClariTEE™ was designed and cleared by the FDA to remain indwelling for 72 hours of episodic hemodynamic monitoring.

**Methods** A structured questionnaire was sent to each intensive care unit in the United Kingdom. The questionnaire detailed information regarding the availability of echocardiography and the frequency that echocardiograms are performed in the ITU. We enquired after the level of training in echocardiography by intensivists, the reporting process and availability of currently provided training. Opinions on the necessity of formalised training and the level of that training were also sought.

**Results** Responses were obtained from 32 units ranging in size from five to 35 critical care beds. A total of 53.13% have their own dedicated echo machine. Only 15.6% have a transoesophageal probe. In 28% of ITUs echocardiograms are performed by intensivists; however, only 25% of ITUs currently offer echocardiography training to intensive care trainees. Seventy-eight per cent of respondents believed that ITU physicians should have at least intermediate echocardiography skills; 97% respondents believed that a national training programme should be established for echocardiography practice by ITU physicians.

**Conclusions** Echocardiography is currently widely used in ITUs throughout the United Kingdom but is often being performed by physicians with little or no formal training. There is almost unanimous support for a national structure and a formalised curriculum to achieve safe widespread training.

Methods The ImaCor system was used to monitor 46 postcardiac surgery patients at two institutions and 68 general ICU patients at eight institutions. Effects on management were recorded and analyzed retrospectively. Economic impact was estimated from [1-4].

Results In 46 postcardiac surgery patients, surgical re-exploration was avoided in five patients (11%), and fluid and pressor administration changed in 23 patients (50%). TEE monitoring also detected tamponade requiring reoperation and helped optimize the LVAD flow rate. Even without including likely reductions in acute kidney injury, a common complication [5], estimated hospital charges (see [1-4]) were reduced by $12,000 per patient. In 68 general ICU patients, fluid and pressor administration was changed in 28 patients (41%), reducing estimated hospital charges by $7,400 per patient.

Conclusions TEE monitoring demonstrated the potential to improve hemodynamic management; expected to reduce hospital stay [6,7]; even small amounts of mild instability significantly increase hospital stay and charges [4]. TEE monitoring also demonstrated the potential to avoid reoperation postcardiac surgery. Reoperation significantly increases morbidity (low cardiac output, acute renal failure, sepsis), vent time, ICU stay and mortality [8]; also cost [1]. Although further study is needed, TEE monitoring has shown potential for significant clinical and economic impact.

P29 Training in focused echocardiography for intensive care specialists: can delivery meet perceived need?

G McNiell1, A Whiteside2, A Tricentei3, D Bryden4
1Sheffield Teaching Hospitals, Sheffield, UK; 2Sheffield Teaching Hospitals NHS Trust, Sheffield, UK

Introduction There is increasing recognition of the utility of focused echocardiography in critically ill patients and a need for suitable training programmes to be developed to meet the specific needs of critical care. Critical care communities across Europe have struggled to implement focused echocardiography into everyday clinical practice. We aim to determine whether a training programme could be implemented during a year of advanced intensive care training in a region where none of the critical care consultant body had accreditation in echocardiography, and to establish the perceived training requirements in critical care echocardiography in our region and to evaluate what information clinicians wished to obtain from a focused echocardiography examination.

Methods Trainees attended a course designed for echocardiography in a peri-arrest situation. Local cardiac anaesthetists with experience in transthoracic echocardiography were recruited as mentors. Data archiving protocols were established. Trainees performed an initial 10 scans directly supervised on the cardiac ICU. A further 40 scans were completed independently on the general ICU. A logbook was maintained and the scans reviewed with a mentor prior to final sign off. This process was supported by a regional educational meeting where personnel interested in echocardiography reviewed the types of training provided and how this matched local needs and resources. This included trainees and trainers in intensive care medicine, anaesthesia and acute medicine.

Results Although 91% of doctors wished to incorporate focused echocardiography into their clinical practice, only 36% had undergone any focused echocardiography training and only 5% had focused echocardiography accreditation. The majority of respondents wished only to incorporate eyeball assessments of ventricular function but did not wish to perform more complex examinations such as Doppler assessment.

Conclusions It is possible to implement a simple training programme in echocardiography in an intensive care medicine department with no prior experience in critical care echocardiography. Within our region there is strong demand for simple training in focused echocardiography rather than a higher level of accreditation currently offered by many courses.

References
correlation of LVM between two different diagnostic techniques, transthoracic echocardiography (TTE) and 64-slice multidetector computed tomography (MDCT).

**Methods** A prospective cohort of 102 patients' LVM was quantified by TTE and MDCT in a row and blind study. We used the following test: intraclass correlation coefficient absolute agreement (ICCA) as a mixed model, concordance correlation coefficient of Lin (CCCL) to evaluate the accuracy, Passing–Bablok regression (PBR) to detect systematic errors and finally the range of Bland–Altman agreement.

**Results** There were 57 (55.8%) males, mean age 65 ± 13 years. ICCA was 0.67 (95% CI: 0.30 to 0.84), P < 0.001; the CCCL was 0.67. The PBR (Y = A + B × X) was: A = −29 (95% CI: −170 to 64), B = 0.70 (95% CI: 0.51 to 0.98). The range of agreement of Bland–Altman showed a mean of X (TTE) − Y (MDCT) = −37.8 (95% CI: −47 to 72) g, there were two cases below the lower limit.

**Conclusions** Both methods show a level of consistency and acceptable accuracy, showing no systematic error constant rate (interval A contains 0) but there seems to be a discrete proportional error (interval B does not contain 1). As shown, the Bland–Altman range seems to slightly overestimate the TTE value against the MDCT, probably related to the quality of the echocardiography window.

Coronary artery disease and differential analysis of a valve calcium score by transthoracic echocardiography

*JL Iribarren, JJ Jimenez, J Lacalzada, A Barragan, M Brouard, I Laynez*

**Hospital Universitario de Canarias, La Laguna, Spain**

**Introduction** Valvular calcification represents a form of atherosclerosis similar to that produced in the wall of the coronary arteries, so that the presence of mitral annular calcification (MAC), aortic valvular sclerosis and aortic root (AVRS) detected by transthoracic echocardiography (TTE) is associated with an increased risk for developing coronary artery disease (CAD). Coronary calcification and intracoronary lesions can be assessed by non-invasive coronary multidetector computed tomography (MDCT). The aim of this study was to determine whether a global valve calcium score (GVCS) and/or partial (MAC and AVRS) assessed by TTE can predict critical values of calcium at the level of the coronary wall, the Agatston score (AS) and/or the presence of significant coronary lesions detected using MDCT.

**Methods** A prospective cohort of 82 patients with intermediate probability of CAD was referred for MDCT and then a TTE was performed in a blind way to calculate the GVCS and partial (range 0 to 15).

**Results** Mean age 65 ± 13 years, 46 (56.1%) males. The area under the curve (AUC) of AS was 0.69 (95% CI: 0.5 to 0.82), P = 0.05. The cut-off value of AS for a higher predictive value to identify the presence of CAD was ≥350 with a sensitivity (S) of 46%, specificity (E) of 86% and a positive predictive value (PPV) and negative predictive value (NPV) of 60% and 78%, respectively. The GVCS value for an AS ≥350 with a higher predictive value was 9. The AUC of GVCS was 0.73 (95% CI: 0.57 to 0.90), P = 0.01 so that a GVCS ≥9 predicts the presence of CAD with 86% (E = 97%), PPV = 83% and NPV = 79%. Spearman’s rho correlation coefficient showed a direct association between AS and GVCS (r = 0.29, P = 0.03), between AS and MAC (r = 0.30, P = 0.03) as well as between AS and AVRS (r = 0.42, P = 0.004). The same coefficient was used to calculate the association between the presence of significant CAD (≥50% stenosis) detected by MDCT and GVCS (r = 0.32, P = 0.005), MAC (r = 0.06, P > 0.05) and AVRS (r = 0.26, P = 0.03). When studying the relationship between single-vessel, double-vessel or triple-vessel CAD and GVCS, MAC and AVRS the following results were obtained respectively: r = 0.33 (P = 0.004), r = 0.06 (P > 0.05) and r = 0.26 (P = 0.03).

**Conclusions** The quantification of valvular calcification using a GVCS by TTE correlates well with the presence of CAD detected by MDCT. This association was stronger when AVRS was used compared with MAC.

National survey of the use of cardiac output monitoring tool in general adult ICUs in the United Kingdom

*O Couppois, S Saha, E Makings*

**Broomfield Hospital, Chelmsford, UK**

**Introduction** Haemodynamic monitoring is essential for the management of critically ill patients. Currently there are various techniques available in clinical practice to measure cardiac output (CO) in ICUs including pulmonary artery catheter (PAC), oesophageal Doppler, lithium dilution cardiac output (LiDCO) and pulse-induced contour cardiac output (PICCO) studies. In recent times PAC has been used less with less invasive methods becoming more popular. We conducted a telephone survey of the current CO monitoring practices in adult ICUs in the United Kingdom.

**Methods** All general adult ICUs in the United Kingdom were surveyed via telephone. The nurse-in-charge or the senior physician for the shift was consulted to ascertain which cardiac output monitors (COMs) were available for use, which was their first choice and if they used PAC in the past 12 months.

**Results** A total of 225 adult ICUs were surveyed and all the replies were recorded on paper (98% response). Two hundred and eleven (96%) units used at least one form of COM while the rest of the 14 units did not use any COM tool. One hundred and two (48%) use more than one form of cardiac output monitoring. Oesophageal Doppler was most popular (86/211, 41%), followed by LiDCO and PICCO both used in 73/211 (35%) of the units, and pulse contour analysis (14/109, 7%). Seven out of 211 (3%) units still use PAC as the preferred method of COM, of these two had other COM devices available and five used PAC only. Forty-six out of 211 (22%) units were using PAC at least occasionally. In contrast, a similar survey performed in 2005 [1] found PAC (76%) and oesophageal Doppler (53%) devices to be the most commonly available. Among the other techniques, 33% of the ICUs use PICCO and a further 19% use LiDCO systems for CO monitoring (Table 1).

**Table 1 (abstract P32). Frequency of cardiac output monitoring across the United Kingdom**

**Conclusions** The results show the changes in COM over the past 5 years in comparison with a previous survey in 2005 [1]. There appears to be a steady decline in the use of PACs, with oesophageal Doppler becoming the most popular method of COM. LiDCO and PICCO are used equally throughout the United Kingdom, with pulse contour analysis becoming less popular.

Hemodynamic monitoring in Swiss ICUs: results from a Web-based survey

*N Siegenthaler, R Giraud, T Saxer, JA Romand, K Bendjelid*

**Hôpital Cantonal Universitaire, Genève, Switzerland**

**Introduction** Adequate and prompt implementation of hemodynamic monitoring is an essential component in the management of critically
ill patients. The goal of the present survey is to assess hemodynamic monitoring strategies in Swiss ICUs.

**Methods** A self-reported Web-based questionnaire (36 multiple-choice questions) was sent by email to available physicians in charge of adult critically ill patients in Swiss ICUs. The survey examined two subjects: the monitoring tool used and how the clinicians address fluid responsiveness. Results where expressed as frequency (% of all replies) and/or presented as a mean rate.

**Results** We obtained 130 replies from 71% of selected Swiss ICUs (general, medical, etc.). Devices available were: echocardiography (Echob): 94.5%, PICCO: 87.3%, Swan-Ganz: 80%, FloTrac™: 21.8%, oesophageal Doppler: 16.4%, LiDCO: 10.9%. The most often device used was: PICCO: 56.7%, Swan-Ganz: 30.7%, Echo: 8.7%, FloTrac™: 3.1%, LiDCO: 0.8% respectively. Clinicians classified (from 1 to 5) the available devices in various situations as follows: during cardiogenic shock: Swan-Ganz (4.27), Echo (4.26), PICCO (3.62), FloTrac™ (2.43); during septic shock: PICCO (4.32), Swan-Ganz (3.76), Echo (3.32), FloTrac™ (2.59); during ARDS: PICCO (4.09), Swan-Ganz (4.01), Echo (3.39), FloTrac™ (2.4). For most of the clinicians, the targeted arterial blood pressure was: 60 to 65 mmHg for 56.2%, 65 to 70 mmHg: 26.9%, 55 to 60 mmHg: 7.7%, 70 to 75 mmHg: 4.6% respectively. The parameters used to predict fluid responsiveness were: PPV: by 58.5% of clinicians, Echo parameters: 55.8%, passive leg rising (PLR) test: 53.8%, SVV 50.0%, GEDV: 45.5%, CO: 45.4%, ScvO₂: 43.1%, systemic arterial pressure: 41.5%, pulmonary artery occlusion pressure (PAOP): 34.6%, EVLW: 33.3%, SVO₂: 31.9%, central venous pressure: 30.8%, variation of inferior vena cava diameter: 27.5%, ITBV: 21.4%, fluid balance: 14.6%, inferior vena cava diameter: 12.5%. Parameters used to stop the vascular filling were: high EVLW: by 51.8% of clinicians, high PAOP: 50.9%, low PPV: 42.6%, high GEDV: 42.0%, disappearance of lactates: 41.9%, Echo parameters: 39.5%, negative PLR test: 38.0%, high ITBV: 30.4%, increase in oxygen requirement: 25.6%, normal CO: 23.3%, elevated CO: 26.0%, high ScvO₂: 18.6%, high SVV: 13.3%.

**Conclusions** This study suggests that clinicians use diverse monitoring methods. Moreover, regarding the parameters used for the fluid management strategy, several parameters are used without a clear predominance for one of them. Furthermore, static indices remain used.

**P34 Prediction of cardiac index by body surface temperatures, ScvO₂, central venous–arterial CO₂ difference and lactate**

W Huber, B Haase, B Saugel, V Phillip, C Schultheiss, J Hoeltlhaler, R Schmid
Klinikum Rechts der Isar der Technischen Universität München, Germany

**Introduction** Monitoring of the cardiac index (CI) is a cornerstone of intensive care. Nevertheless, most of the techniques based on indicator dilution and/or pulse contour analysis require central venous and/or arterial catheters. Several surrogate markers have been suggested to estimate CI including ScvO₂, central venous–arterial CO₂ difference (CvACO₂D) as well as body surface temperatures and their differences to body core temperature (BCT). It was the aim of our prospective study to evaluate the predictive capabilities of CvACO₂D, ScvO₂, surface temperatures and lactate regarding CI.

**Methods** In 53 patients (33 male; 20 female) with PICCO monitoring, 106 datasets including surface temperatures of great toe, finger pad, forearm and forehead using an infrared non-contact thermometer (Thermofocus; Tecnimed) as well as lactate, ScvO₂, CvACO₂D and pulse pressure (PP) were measured immediately before PICCO thermodilution proving CI and SVRI. Statistics: SPSS 18.0.

**Results** Patients: 17/53 (32%) ARDS; 14/53 (26%) liver cirrhosis; 13/53 (25%) sepsis; 4/53 (8%) cardiogenic shock; 5/53 (9%) various aetiologies. Thermodilution-derived CI significantly correlated to the temperatures of the forearm (r = 0.465; P < 0.001), great toe (r = 0.454; P < 0.001), finger pad (r = 0.447; P < 0.001) and forehead (r = 0.392; P < 0.001) as well as to ScvO₂ (r = 0.355; P < 0.001), CvACO₂D (r = -0.244; P = 0.011) and pulse pressure (r = 0.226; P = 0.019), but not to lactate (r = -0.067; P = 0.496). ROC analysis regarding the critical threshold of CI <2.5 L/minute*sqm demonstrated the highest predictive capabilities for the differences (BCT – T-forearm) (ROC-AUC 0.835; P = 0.002; cut-off 4.6); sensitivity 89%; specificity 71%) and (BCT – T-finger pad) (ROC-AUC 0.757; P = 0.017) as well as ScvO₂ (ROC-AUC 0.744; P = 0.024). CvACO₂D (ROC-AUC 0.706; P = 0.056) and lactate (ROC-AUC 0.539; P = 0.718) were not predictive. Multiple regression analysis (R = 0.725) demonstrated that age (P < 0.001), PP (P < 0.001), T-forearm (P = 0.024) and the difference (BCT – T-toe; P = 0.035) were independently associated with CI.

**Conclusions** Body surface temperatures and their differences to BCT are useful to estimate CI. The difference (BCT – T-forearm) provided the largest ROC-AUC (0.835; P = 0.002) regarding CI <2.5 L/minute*sqm. CvACO₂D does not provide information in addition to body surface temperatures and ScvO₂.

**P35 Impact of hepatic venous oxygen efflux and carotid blood flow on the difference between mixed and central venous oxygen saturation**

T Correa, R Kindler, S Brandt, J Gorrasl, T Regueira, H Bracht, F Porta, J Takala, R Pearse, S Mathias Jakob
1University Hospital Bern – Inselhospital and University of Bern, Switzerland;
2Royal London Hospital, London, UK

**Introduction** The difference between central venous (ScvO₂) and mixed venous oxygen saturation (SvO₂) may vary widely. The objective of this study was to evaluate the impact of hepatic and renal venous oxygen efflux, femoral oxygen saturation and carotid artery blood flow on the difference between ScvO₂ and SvO₂ (Δ[ScvO₂ – SvO₂]).

**Methods** Nineteen sedated and mechanically ventilated pigs (weight: 41.0 ± 3.6 kg) were subjected to sepsis (n = 8), hypoxic hypopaxia (n = 3) and cardiac tamponade (n = 3) or served as controls (n = 5). Mixed, central and regional venous oxygen saturations (spectrophotometry), and carotid, hepatic and renal blood flows (ultrasound Doppler flow) were measured at baseline and 3 hourly, up to 24 hours. Hepatic venous oxygen efflux was determined as hepatic arterial + portal venous blood flow times hepatic venous oxygen content, and renal venous oxygen efflux as twice renal artery blood flow times renal venous oxygen content, and renal venous oxygen efflux as twice renal artery blood flow times renal venous oxygen content. A multiple linear regression analysis with backward elimination procedure was undertaken to define contributions of the variables to Δ[ScvO₂ – SvO₂].

**Results** Ninety-eight assessments were obtained (one to seven/animal). The backward elimination procedure yielded a best model containing hepatic venous oxygen efflux (r = -0.46, P < 0.01) and carotid artery blood flow (r = 0.56, P < 0.01; Figure 1). This final model accounted for 49.8% of variation in Δ[ScvO₂ – SvO₂] (R² = 0.498).

**Conclusions** Carotid artery blood flow and hepatic but not renal venous oxygen efflux predict some of the differences between mixed
and central venous oxygen saturation. As a consequence, SvO₂ cannot be predicted by ScvO₂ alone.

**P36**

Goal-directed fluid management based on stroke volume variation and stroke volume optimization during high-risk surgery: a pilot multicentre randomized controlled trial

TW Scheeren1, C Wiesenack1, H Gerlach2, G Marx3
1University Medical Center Groningen, the Netherlands; 2Marienhospital, Gelsenkirchen, Germany; 3Vivantes – Klinikum Neukoelln, Berlin, Germany; 4University Hospital RWTH, Aachen, Germany

**Introduction** Perioperative hemodynamic optimization has been shown to be useful to improve the postoperative outcome of patients undergoing major surgery. We designed a pilot study in patients undergoing major abdominal, urologic or vascular surgery to investigate the effects of a goal-directed (GD) fluid management based on continuous stroke volume variation (SVV) and stroke volume (SV) monitoring on postoperative outcomes.

**Methods** Fifty-two high-risk-surgical patients (ASA 3 or 4, arterial and central venous catheter in place, postoperative admission in ICU) were randomized either to a control group (Group C, n = 26) or to a goal-directed group (Group G, n = 26). Patients with cardiac arrhythmia or ventilated with a tidal volume <7 ml/kg were excluded. In Group G, SVV and SV were continuously monitored with the FloTrac™/Vigileo™ system (Edwards Lifesciences, USA) and patients were brought to and maintained on the plateau of the Frank–Starling curve (SVV <10% and SV increase <10% in response to fluid loading). During the ICU stay, organ dysfunction was assessed using the SOFA score and resource utilization using the TISS score. Patients were followed up to 28 days after surgery for infectious, cardiac, respiratory, renal, hematologic and abdominal complications.

**Results** Group G and Group C were comparable for ASA score, comorbidities, types and duration of surgery (275 vs. 280 minutes), heart rate, MAP and CVP at the start of surgery. However, Group G was younger than Group C (68 vs. 73 years, P < 0.05). During surgery, Group G received more colloid than Group C (1,589 vs. 927 ml, P < 0.05) and SVV decreased in Group G (from 9.0 to 8.0%, P < 0.05) but not in Group C. The number of postoperative wound infections was lower in Group G (0 vs. 7, P < 0.01). Although not statistically significant, the proportion of patients with at least one complication (46 vs. 62%), the number of postoperative complications per patient (0.65 vs. 1.40), the maximum ICU SOFA score (5.9 vs. 7.2), and the cumulative ICU TISS score (69 vs. 83) were also lower in Group G. ICU and hospital length of stay were <0.05) but not in Group G received more colloids than Group C (1,589 vs. 927 ml, P < 0.05). During surgery, Group G received more colloid than Group C (1,589 vs. 927 ml, P < 0.05) and SVV decreased in Group G (from 9.0 to 8.0%, P < 0.05) but not in Group C. The number of postoperative wound infections was lower in Group G (0 vs. 7, P < 0.01). Although not statistically significant, the proportion of patients with at least one complication (46 vs. 62%), the number of postoperative complications per patient (0.65 vs. 1.40), the maximum ICU SOFA score (5.9 vs. 7.2), and the cumulative ICU TISS score (69 vs. 83) were also lower in Group G. ICU and hospital length of stay were similar in both groups.

**Conclusions** Although the two groups were not perfectly matched, this pilot shows that fluid management based on SVV and SV optimization decreases wound infections. It also suggests that such a GD strategy may decrease postoperative organ dysfunction and resource utilization. However, this remains to be confirmed by a larger study.

Prognostic value of dynamic variation of tissue oxygen saturation during severe cardiogenic shock

P Gaudard, J Eliot, O Attard, P Colson
CHRU, Montpellier, France

**Introduction** To evaluate the prognostic value of dynamic thenar Q saturation (StO₂) response using a vascular occlusion test (VOT) during cardiogenic shock.

**Methods** A retrospective clinical observational analysis was performed on adult patients treated for severe cardiogenic shock in a surgical ICU. The non-invasive InSpectra near-infrared spectrometer was used to assess the effect of VOT on thenar eminence StO₂. The VOT manoeuvre was repeated within the first 24 hours of admission. StO₂, VOT-induced changes were compared between surviving and nonsurviving patients between the first 8 hours and the next 16 hours.

**Figure 1 (abstract P37).** StO₂ recovery slope (mean).

**Results** Ten patients suffering from cardiogenic shock (age 59.8 ± 13.8 years; APACHE score 21.3 ± 5.9) were treated with inotropes (n = 7) and/or circulatory mechanical assistance (four IABP, three ELS, one LVAD) and vasopressors (n = 9). Mortality in the ICU was 50%. Hemodynamic and metabolic parameters were not different between survivors and nonsurvivors (Table 1). The post-VOT StO₂ recovery slope tended to be faster within the first 8 hours in survivors than in nonsurvivors (2.8 ± 1.1 vs. 1.7 ± 0.4%/s, P = 0.09) and improved significantly in the H8 to H24 period (4.5 ± 1.2 vs. 2 ± 1.1%/s, P = 0.007). The post-VOT StO₂ recovery slope increased significantly within the first 24 hours in all survivors (Figure 1).

**Conclusions** Our results suggest that, in patients treated for cardiogenic shock, rapid improvement in the post-VOT StO₂ recovery slope is associated with a better prognosis.

**P38**

Prognostic value of the central venous-to-arterial carbon dioxide difference for postoperative complications in high-risk surgical patients

E Robin1, E Futier2, O Pires1, G Lebuffe1, B Vallet1
1University Hospital of Lille, Université Nord de France, Lille, France; 2University Hospital of Clermont-Ferrand, France

**Introduction** Tissue hypoperfusion is a key trigger of postoperative organ dysfunction. Our objective was to evaluate the prognostic value of the central venous-to-arterial carbon dioxide difference (PCO₂ gap), a global index of tissue perfusion, in patients after major abdominal surgery.

**Methods** A prospective and observational study of 115 patients admitted to the ICU following major abdominal surgery. In all patients, measurements of the PCO₂ gap, central venous oxygen saturation (ScvO₂), serum lactate and conventional hemodynamic and biological parameters were performed on admission (H0), and over 6 hours until 12 hours after admission. Postoperative complications, the duration of mechanical ventilation, and the hospital length of stay and mortality up to 28 days were characterized using standard definitions. Area under the ROC curves for PCO₂ gap, ScvO₂ and lactate were calculated and compared to discriminate between patients with and without complications.

**Results** A total of 78 patients developed at least one complication including 57 (50%) patients with postoperative septic complications.
At T0 there was no significant difference in demographic and hemodynamic data, type and duration of surgical procedures between patients with and without complications. There were nine deaths (7.8%). There was a significant difference for PCO\(_2\) gap (8.1 ± 3.2 mmHg vs. 5.5 ± 2.8 mmHg, \(P < 0.001\)), ScvO\(_2\) (76.5 ± 6.4% vs. 78.9 ± 5.8%), and serum lactate (\(P < 0.001\)) between patients with and without complications. After multivariate analysis, PCO\(_2\) gap and lactate level, but not ScvO\(_2\), were associated with postoperative complications (\(P < 0.001\) and \(P = 0.018\), respectively). Areas under the ROC curves were 0.66 (95% CI = 0.57 to 0.74) for lactate, 0.75 (95% CI = 0.65 to 0.85) for ScvO\(_2\), and 0.85 (95% CI = 0.77 to 0.93) for PCO\(_2\) gap, with 6 mmHg as the best threshold value for discriminating patients with and without complications. Patients with a PCO\(_2\) gap >6 mmHg (68%) had a longer duration of mechanical ventilation (4.1 ± 3.4 days vs. 5.6 ± 3.8 days, \(P = 0.047\)), and a longer hospital stay. Patients who died all had an enlarged PCO\(_2\) gap (\(P = 0.056\)).

Conclusions Both low and supranormal values of ScvO\(_2\) were found to be warning signals of impaired tissue oxygenation. A PCO\(_2\) gap larger than 6 mmHg could be a useful prognostic factor to identify patients at risk of postoperative complications following major abdominal surgery, especially when ScvO\(_2\) exceeds 75%.

P39 Continuous central venous saturation monitoring in critically ill patients

D Chiumello\(^1\), M Cressoni\(^1\), A Marino\(^2\), E Gallazzi\(^2\), C Mietto\(^2\), V Berto\(^2\), M Chierichetti\(^2\)

\(^1\)Fondazione IRCCS Ca’ Granda-Ospedale Maggiore Policlinico, Milan, Italy; \(^2\)Università degli Studi di Milano, Milan, Italy

Introduction Central venous oxygen saturation (ScvO\(_2\)) is a useful therapeutic target in septic shock. ScvO\(_2\) is an indirect index of the balance between oxygen supply and demand, and critically ill patients falling in ScvO\(_2\) reflects a decrease in tissue oxygenation. ScvO\(_2\) depends on arterial oxygen saturation, oxygen consumption, cardiac output and hemoglobin.

The aim of the study was to evaluate events of tissue oxygenation impairment that could be unrecognized by simple blood gas analysis, by continuously monitoring ScvO\(_2\), and to establish whether peripheral oxygen saturation (SpO\(_2\)), mean arterial pressure (MAP), heart rate (HR), and central venous pressure (CVP) could predict LowScvO\(_2\) events.

Methods Ventilated critically ill patients requiring a central venous catheter (CVC) for clinical use were enrolled. Continuous ScvO\(_2\) monitoring was obtained by a fiberoptic sensor inserted in the CVC and recorded for 72 hours with SpO\(_2\), HR, MAP, and CVP. LowScvO\(_2\) events were defined as ScvO\(_2\) <55% maintained for at least 5 minutes.

Results Thirty-seven patients (24 males) were enrolled. The mean clinical characteristics at admission to intensive care were: age 59 ± 16 years, BMI 26.1 ± 4.5 kg/m\(^2\), SAPS II 40 ± 13 (on 33 patients), PaO\(_2\)/FiO\(_2\) 206 ± 79, MAP 80 ± 13 mmHg, HR 92 ± 21 bpm, CVP 12 ± 3 mmHg, Hb 10.6 ± 1.9 g/dl. Continuous monitoring analysis detected 147 LowScvO\(_2\) events in 15 patients; while central venous blood gas analysis identified only nine LowScvO\(_2\) events in eight patients (6%). Table 1 summarizes patients’ variables according to three ScvO\(_2\) ranges. ScvO\(_2\), HR, MAP, and CVP were not correlated with LowScvO\(_2\) events. Most patients had long periods of ScvO\(_2\) >75 (supranormal ScvO\(_2\)).

Conclusions Continuous ScvO\(_2\) monitoring showed that most events of poor tissue oxygenation are relatively common, are not recognized by extemporary central venous blood gas analysis and are not mirrored by changes in SpO\(_2\), HR, MAP, or CVP.

P40 Femoral venous oxygen saturation is no surrogate for central venous oxygen saturation

A Van der Schors\(^1\), P Van Beest\(^1\), H Liebers\(^1\), L Coenen\(^1\), R Braam\(^1\), P Spronk\(^1\)

\(^1\)Gelse Hospitals, Apeldoorn, the Netherlands; \(^2\)University Medical Center, Groningen, the Netherlands

Introduction Shock is defined as global tissue hypoxia secondary to a mismatch between systemic oxygen delivery (DO\(_2\)) and oxygen demand (VO\(_2\)), reflected by mixed venous oxygen saturation (SvO\(_2\)). Intervention based on markers of tissue hypoperfusion may improve outcome. Central venous oxygen saturation (ScvO\(_2\)) has been used as a surrogate marker for SvO\(_2\). In order to monitor ScvO\(_2\) during resuscitation, an internal jugular or subclavian line must be inserted. However, sometimes the femoral vein is the preferred or only possible site for access. The purpose of our study is to determine whether ScvO\(_2\) and femoral venous oxygen saturation (SfvO\(_2\)) can be used interchangeably.

Methods A single-center, prospective, controlled, observational study was conducted at the Gelse Hospitals Apeldoorn. One hundred stable cardiac patients who underwent elective right heart catheterization in days were served as a control group (high-risk surgery, ASA 2, n = 30) we determined SfvO\(_2\), and ScvO\(_2\), simultaneously at the start (T = 0) and at the end (T = 1) of the procedure. For each time point we calculated the agreement and difference between both values.

Results Control group: ScvO\(_2\) and SfvO\(_2\) correlated significantly (r = 0.67, 95% CI = 0.50 to 0.80, P < 0.0001) with large limits of agreement (bias 2.0 ± 7.1; –11.8 to 15.9). In the surgical patients at T = 0, mean values were similar (SfvO\(_2\) 82.5 ± 6.6% vs. ScvO\(_2\) 81.1 ± 8.1; P = 0.28).

According to Bland–Altman analysis, the mean bias between ScvO\(_2\) and SfvO\(_2\) was 2.7 ± 7.9% and 95% limits of agreement were large (–12.9% to 18.2%), while correlation between ScvO\(_2\) and SfvO\(_2\) was significant (r = 0.35; P < 0.01). At both time points SfvO\(_2\) and ScvO\(_2\) did not correlate significantly (P = 0.26 and P = 0.66 respectively) with similar negligible r\(^2\). Univariate analysis did not show any parameter (including dosages of dopamine or norepinephrine, total infusion, fluid balance, FiO\(_2\), type of surgery, lactate, and haemoglobin level) affecting either SfvO\(_2\) or ScvO\(_2\). Results were similar for changes in SfvO\(_2\) and changes in ScvO\(_2\).

Conclusions Absolute values of SfvO\(_2\) are unsuitable as surrogate for absolute values of ScvO\(_2\). Also, the trends of both values are not interchangeable. Further studies should investigate the effects of treatment on SfvO\(_2\).
(P = 0.006) in survivors but remained persistently low in nonsurvivors. The AUROC for STo2 was 0.63 on ED departure and 0.71 after 24 hours of treatment, performing far better than heart rate (0.53), SpO2 (0.50) and systolic blood pressure (0.51). There was no correlation between STo2 and any of the routine vital signs.

**Conclusions** Our results demonstrate that a consistently low tissue oxygen saturation despite initial sepsis resuscitation is associated with an increased in-hospital mortality. We have further shown that tissue oxygen saturation is a better prognostic indicator than conventional vital signs in severely septic ED patients.

Lactate index and survival in hospital-acquired septic shock

S Omar1, Matthiha1, J Dulhunty1, A Lundgren2
1University of Witwatersrand, Johannesburg, South Africa; 2University of Queensland, Brisbane, Australia

**Introduction** Severe sepsis is characterised by profound metabolic and inflammatory derangement, which can lead to multiorgan failure and death. During septic shock, oxygen delivery may fail to meet tissue demand resulting in increased oxygen extraction. Once tissue needs are no longer met, an oxygen debt with global tissue hypoxia and associated hyperlactataemia ensues. Several studies have shown that blood lactate may be used as a marker of global tissue hypoxia and prognosis in shock states.

**Methods** Forty patients requiring adrenaline therapy for a first episode of septic shock acquired >24 hours after admission to the ICU had blood lactate levels measured 2-hourly over a 24-hour period. Adrenaline therapy was escalated until the target mean arterial pressure was reached. The lactate index was calculated as the ratio of maximum lactate increase to the adrenaline increase.

**Results** Lactate increased from 2.3 to 2.9 mmol/l (P = 0.024) and the mean adrenaline increase was 0.14 μg/kg/minute. Peak lactate correlated with peak adrenaline (rho = 0.34, P = 0.032). Lactate index was the only independent predictor of survival after controlling for age and APACHE II score (OR = 1.14, 95% CI = 1.03 to 1.26, P = 0.009).

**Conclusions** A high lactate following adrenaline administration may be a beneficial and appropriate response.

vs. 4.5 ± 1.1 (P = 0.002) and, also, T30 and T60 (4.5 ± 1.1 vs. 5.0 ± 1.3, P = 0.009). Auto-PEEP values were inversely correlated with decreased P vs. 4.5 ± 1.1, T30 and T60 (4.5 ± 1.1 vs. 5.0 ± 1.3, P = 0.009).

Conclusion Minute ventilation had an effect on dPCO₂ by reduced CO due to development of auto-PEEP. The dPCO₂ should be measured during normal minute ventilation without auto-PEEP.

A pulmonary artery catheter-based treatment algorithm changes therapeutic behaviour in septic patients
C Bethel, FM Groenwold, MA Kuiper, M Koopmans, EC Boerma
1 Medical Centre Leeuwarden, the Netherlands; 2 University Medical Centre Groningen, the Netherlands

Introduction For years the role of the pulmonary artery catheter (PAC) in ICU patients has been a topic of discussion. The use of PAC itself is not associated with improved outcome, and might contribute to increased morbidity [1]. However, the influence of a therapeutic strategy, based on dynamic PAC-derived variables, has never been investigated. The aim of this study is to evaluate whether such PAC-based strategy influences therapeutic behaviour in septic patients.

Methods We performed a single-centre retrospective case–control study in a 22-bed mixed ICU. Seventy patients with severe sepsis or septic shock, treated after introduction of a strict PAC-based resuscitation protocol, were compared with 70 matched controls, treated at the discretion of the attending physician. Continuous PAC measurements (Vigilance®) were started within 4 hours of admission. In short, the treatment algorithm only allowed infusion of fluids in cases of a 10% rise in left ventricular stroke volume; administration of dopamine was titrated on cardiac index in combination with central venous oxygen saturation. Norepinephrine was administered in cases of persistent hypotension despite the first two steps [2]. Primary outcomes were cumulative fluid balance and maximum dose of dopamine and norepinephrine in the first 24 hours. Statistical comparison between groups was performed with applicable tests; data are expressed as median (IQR).

Results At ICU admission there were no differences in severity of disease or predicted mortality using the APACHE IV model. The cumulative fluid balance in the first 24 hours was significantly higher in the PAC group, in comparison with controls (6.0 (4.3 to 7.5) l vs. 3.6 (1.8 to 5.0), P = 0.000). However, after 7 days cumulative fluid balance was significantly lower in the PAC group (7.5 (4.6 to 13.1) l vs. 13.0 (6.7 to 17.7), P = 0.0002). Maximum dose of norepinephrine in the first 24 hours was significantly higher in the PAC group (0.12 (0.03 to 0.19) μg/kg/minute vs. 0.02 (0 to 0.07) μg/kg/minute, P = 0.000). No difference in use of dopamine was found. There was a significant difference in days on mechanical ventilation in favour of the PAC group (7 (5.0 to 11.3) days vs. 10 (5.8 to 18.3) days, P = 0.01).

Conclusions A treatment strategy, based on dynamic PAC-derived parameters in septic patients, significantly alters fluid administration, use of norepinephrine and days on mechanical ventilation, in comparison with historic controls.

Methods Anesthetized, mechanically ventilated lambs were instrumented with a COLD® (Pulsion Medical Systems, Munich, Germany) catheter and underwent repetitive saline lavage (10 to 30 ml/kg) of the lung. CO was measured using the single indicator TPTD method (COTPTD) and compared with simultaneous measurement of CO using an ultrasound perivascular flowprobe (Transonic Systems, USA) around the main pulmonary artery (COMPA). EVLW was assessed by the transpulmonary double indicator technique with intravenous injections of ice-cold indocyanine green (ICG).

Results A total of 62 simultaneous measurements in 11 lambs were analyzed. The mean body weight was 8.6 (range 4.1 to 12.3) kg. The initial EVLW was 13.8 (range 9.3 to 21.5) ml/kg. After lung injury this increased to 38.3 (range 16.2 to 60.9) ml/kg. The mean COMPA was 1.52 (range 0.4 to 3.05) l/min. The correlation coefficient between the COMPA and COTPTD was 0.93. The Bland–Altman analysis showed a mean bias of –0.09 l/min (limits of agreement ± 0.37 l/min) (Figure 1). The percentage error was 25%.

Conclusions In circumstances of largely increased extravascular lung water, CO can reliably be measured using the TPTD technique.

P48 Hemodynamic effects of early endotoxia on pulse pressure variation during experimental hemorrhagic shock
J Noel-Morgan, DT Fantoni, DA Otsuki, JO Auler Jr
Faculdade de Medicina da Universidade de São Paulo, Brazil

Introduction Although pulse pressure variation (PPV) is essentially proposed as a predictor of fluid responsiveness [1], it has also been appointed as an early detector of hypovolemia [2]. Still, caution has been recommended for its employment in certain conditions, as during pulmonary hypertension (PH) [2,3]. Endotoxin-induced PH produces a decrease in CO that can be used to predict fluid responsiveness [1]. SVV has also been proposed as a predictor of fluid responsiveness [1], it has also been used to monitor fluid resuscitation. Still, caution has been recommended for its employment in certain conditions, as during PH.

Methods Forty-nine fully ventilated patients in sinus rhythm were admitted postoperatively to the ICU monitored with pulse power analysis (PulseCO; LIDCO, Cambridge, UK). Fluid challenge (FC) consisted of 250 ml colloid over 5 minutes. Responder: SV increase >10%. ΔCVP was used to define two groups of patients: A (ΔCVP > 1 mmHg) and B (ΔCVP < 2 mmHg).

Results Eighty-two FCs were performed. There were 33% responders in A versus 36% in B (not significant). For A + B, SVV and PPV AUCs were 0.81 and 0.78. There was no statistically significant difference in the AUC for SVV and PPV between A and B, but there were different best cut-off values (Table 1).

Table 1 (abstract P49)

Conclusions Our data suggest that SVV/PPV efficacy in predicting a fluid response cannot be improved by looking at ΔCVP. More patients are needed to investigate the relationship between ΔCVP and best cut-off values for SVV and PPV.

P50 Comparison between pulse pressure variation and conventional parameters as guides to resuscitation in a pig model of acute hemorrhagic shock with endotoxia
J Noel-Morgan, DT Fantoni, DA Otsuki, JO Auler Jr
Faculdade de Medicina da Universidade de São Paulo, Brazil

Introduction Volume expansion is often used in anesthesia and critical care to improve oxygen delivery and, in mechanically ventilated...
patients, pulse pressure variation (PPV) has been proposed as an index to aid in the assessment of the appropriate amount of fluids to be administered to this end [1]. The objective of this study was to compare PPV with conventional parameters as guides to resuscitation, in an experimental model of severe hemorrhagic shock with endotoxemia.

**Methods** Twenty-seven anesthetized, mechanically ventilated pigs were submitted to acute hemorrhagic shock with infusion of endotoxin. Animals were randomly allocated to three groups: control (n = 9); conventional treatment with lacted Ringer’s (LR) to achieve and maintain central venous pressure (CVP) ≥12 mmHg, mean arterial pressure (MAP) ≥65 mmHg, mean arterial pressure (MAP) ≥65 mmHg, mean arterial oxygen saturation (SvO2) ≥65% (CNV, n = 9); or LR to achieve and maintain PPV ≤13% and MAP ≥65 mmHg (dPP, n = 9). Hemodynamic parameters, measured by pulmonary artery catheter and femoral arterial catheter, and blood gases were assessed at baseline (TB), 1 hour after hemorrhage (TS), and hourly during the treatment period (T1 to T3). Groups and times were compared with two-way ANOVA followed by Tukey test and t-test was used for comparisons of treatment times and LR amounts (P < 0.05).

**Results** At TS all groups presented equivalent, significant decreases in cardiac index (CI), MAP, CVP, SvO2, and oxygen delivery index (DOJ) and an increase in PPV (all P < 0.001). At T3, both treated groups presented hemodynamic recovery, with no statistical difference from TB or each other for CI, MAP, SvO2, DOJ or PPV. Statistically, there were no differences in times or amounts of LR to achieve endpoints, for maintenance or in total amounts of LR given. The only statistical difference between treatment groups involved CVP, which was higher in group CNV than in group dPP at T2 (P = 0.009) and T3 (P < 0.001). CVP was also higher at T3, in group CNV, when compared with TB (P = 0.006).

**Conclusions** Although early fluid management guided by PPV yielded similar hemodynamic results to those achieved by management through conventional parameters, a difference could be noted regarding CVP, which was maintained higher in group CNV, but was restored to baseline values by PPV-guided therapy. The clinical impacts of such occurrences remain to be determined.

**PS1** Fluid resuscitation based on dynamic predictors of fluid responsiveness: closed loop algorithm versus anesthesiologists

J Rinehart, B Alexander, L Meng, M Cannesson
University of California Irvine, Orange, CA, USA

**Introduction** Closed-loop management of fluid resuscitation has historically been difficult. Given the dynamic predictors of fluid responsiveness, automated management is now feasible. We present simulation data for a novel patient-adaptive closed-loop fluid management algorithm using pulse pressure variation (PPV) as the input variable.

**Methods** Using a simulator that includes physiologic PPV output, 20 practicing anesthesiology residents and faculty were asked to manage fluids and pressors for a 1-hour simulated hemorrhage case of 2 l blood loss over 20 minutes (group 1). One week later, they repeated the simulation, but this time fluids were secretly managed by the closed-loop system while practitioner fluid administrations were ignored and only the pressors were entered (group 2). The simulation was also run 20 times with only the closed-loop (group 3) and 20 times with no management (group 4).

**Results** Conditions across all groups were similar at baseline for simulated patient weight, height, heart rate (HR), mean arterial pressure (MAP), and cardiac output (CO). Once the hemorrhage began, the closed loop groups (2 and 3) intervened significantly earlier than the practitioners (group 1) and gave more fluid. The mean and final CO was higher in both closed-loop groups than in the practitioner group, and the coefficient of variance was lower. There was no difference in MAP between intervention groups, but all were significantly higher than the unmanaged group. See Figure 1.

**Conclusions** Our data demonstrate that closed-loop management of fluid resuscitation is feasible using our novel dynamic-parameter based algorithm and that this approach can be used to optimize cardiac output.

**PS2** A strong relationship between respiratory variations in pulse pressure (PPV) and airway pressure in fluid nonresponders: a potential explanation for false positive PPV values

LO Hoiseth
Oslo University Hospital, Oslo, Norway

**Introduction** Respiratory variations in pulse pressure (PPV) during mechanical ventilation predict fluid responsiveness when the tidal volume is >8 ml/kg [1]. The effect of airway pressure on the ability of PPV to predict fluid responsiveness is less explored. In patients undergoing major abdominal surgery, we found low specificity of PPV and therefore explored the relation between peak airway pressure (Paw) and PPV in fluid challenge nonresponders.

**Methods** Twenty-five patients scheduled for open abdominal surgery with volume controlled ventilation 8 ml/kg, I:E ratio 1:2 and PEEP 5 cmH2O were included. Fluid challenges of 250 ml colloid were administered at the discretion of the anesthesiologist. PPV, hemodynamic variables, Paw and stroke volume (SV) measured by oesophageal Doppler were recorded before and after fluid challenges. Responders were defined by an increase in SV >15%.

**Results** Thirty-four fluid challenges were performed. Further data are from analysis of nonresponders; 12 fluid challenges in 11 patients.

---

**Figure 1 (abstract PS1).** Data are mean ± SD. *P < 0.05 versus groups 2, 3, 4; **P < 0.05 versus groups 1 and 4.
Specificity of PPV was 0.67. By fluid challenge, PPV was reduced from 7.4 (6.2 to 15.2)% to 6.0 (4.4 to 9.8)% (median, 25th to 75th percentiles), whereas Paw and SV were unchanged. Before fluid challenge, Paw was significantly correlated with PPV (r = 0.91, P < 0.001) (Figure 1).

Conclusions In this study on patients undergoing open abdominal surgery ventilated with 8 ml/kg, specificity of PPV was low. Paw and PPV were strongly correlated and false positive PPVs were associated with high Paw. This finding indicates that not only tidal volume, but PPV were strongly correlated and false positive PPVs were associated with high Paw. This finding indicates that not only tidal volume, but PPV were strongly correlated and false positive PPVs were associated with high Paw.

Prediction of fluid responsiveness in septic shock patients: comparing automated pulse pressure variation by IntelliVue MP monitor and stroke volume variation by FloTrac™/Vigileo™
B Khwannimit1, R Bhurayanontachai2
1 Songklanagarind Hospital, Songkhla, Thailand; 2 Division of Critical Care

Introduction The aim of this study was to assess and compare the ability of the automatically and continuously measured pulse pressure variation (PPV) obtained by an IntelliVue MP monitor and stroke volume variation (SVV) measured by FloTrac™/Vigileo™ to predict fluid responsiveness in septic shock patients.

Methods We conducted a prospective study on 42 mechanically ventilated septic shock patients. SVV, PPV and other hemodynamic data were recorded before and after fluid administration with 500 ml of 6% tetrastarch. Responders were defined as patients with an increase in cardiac index ≥15% after fluid loading.

Results The agreement (mean bias ± SD) between PPV and SVV was -0.59 ± 1.72% (Figure 1). The baseline PPV correlated with the baseline SVV (r = 0.96, P < 0.001). Twenty-seven (64.3%) patients were classified as fluid responders. PPV and SVV were significantly higher in responders than in nonresponders (16.2 ± 4.9 vs. 7.1 ± 2% and 15.3 ± 4.3 vs. 6.9 ± 1.9%, respectively, P < 0.001 for both). There was no difference between the area under the receiver operating characteristic curves of PPV (0.983) and SVV (0.99). The optimal threshold values to predicting fluid responsiveness were 10% for PPV (sensitivity 92.6%, specificity 86.7%) and 10% for SVV (sensitivity 92.6%, specificity 100%).

Conclusions The automated PPV, obtained by the Intellivue MP monitor, and the SVV, obtained by FloTrac™/Vigileo™, showed comparable performance in terms of predicting fluid responsiveness in mechanically ventilated patients with septic shock.

Dynamic indices of preload in postcardiac surgery patients by pulse power analysis
E Barbon, F Calandro, J Kamdar, M Puntis, H Meeran, A Rhodes, A Dowhurst, M Cecconi
St Georges Hospital, London, UK

Introduction The ability to predict fluid responsiveness during the perioperative period is important in order to minimize the risk of hypovolemia and fluid overload. We studied the ability of dynamic indices [1] such as pulse pressure variation (PPV) and stroke volume variation (SVV) measured with the LiDCO™rapid to predict the response in stroke volume (SV) after a fluid challenge (FC).

Methods This was a prospective observational study of FCs (250 ml colloid given in less than 5 minutes) in the immediate postoperative period in cardiac surgery patients. A positive response to a FC was defined as an increase in SV >10% measured with LiDCO™rapid. FCs were repeated according to the unit protocol. PPV and SVV were recorded before FC, together with static haemodynamic measurements: mean arterial pressure (MAP), central venous pressure (CVP) and heart rate (HR). Receiving operator characteristic (ROC) analysis was performed in order to identify haemodynamic variables suitable to predict fluid responsiveness.

Results Sixteen patients were enrolled; five females, 11 males, age 70 (±11) years, weight 82 (±13) kg, height 167 (±10) cm. Of the 16 patients, seven (44%) were fluid responders to the first FC. A total number of 47 FCs were given. There were no differences in HR, CVP and MAP between responders and nonresponders. PPV and SVV were significantly different between responders and nonresponders. Areas under the curve for ROC curves were: for PPV 0.76 (0.61 to 0.92), P = 0.003, and for SVV 0.80 (0.67 to 0.93), P = 0.0006. The best cut-off values (sensitivity and specificity) to predict a 5% increase >10% after FC were: PPV >13.5% (79%, 72%), and SVV >10.5% (84%, 68%).

Conclusions Dynamic indices measured by LiDCO™rapid have a high sensitivity and specificity in predicting fluid responsiveness in fully sedated and mechanically ventilated patients postcardiac surgery.

Cardiac cycle efficiency as prognostic index in ICUs
A Donati, S Loggi, C Scorcella, MR Lombrano, L Botticelli, MC Melia, A Carsetti, R Domizi, S Tonchi, P Pelaia
Università Politecnica delle Marche, Ancona, Italy

Introduction Cardiac cycle efficiency (CCE) can be calculated by the pressure recording analytical method (PRAM), a mini-invasive pulse-contour system that can provide beat-to-beat monitoring of cardiac output [1]. CCE is a new parameter that ranges from –1 to +1, with –1 being the worse and +1 the best possible performance of the cardiac cycle in terms of hemodynamic balance maintenance [2]. These characteristics make CCE a possible prognostic index, especially in critical patients who often present hemodynamic instability.

Methods We recruited 157 consecutive patients admitted to the ICU undergoing hemodynamic monitoring, and the following parameters were registered in the first 24 hours from the admission: hemodynamic parameters (cardiac index, dp/dt max and CCE) detected from the MostCare monitor (based on the PRAM algorithm), PaO2/FiO2 ratio, arterial lactates, SAPS II. We also divided the patients into seven diagnostic categories and take note of the outcome.

Results We inserted all data into the logistic regression analysis model. The significant variables that take place in the regression equation...
Inhalant anesthetic agents have dose-dependent hemodynamic and respiratory effects.

Introduction

Pulse pressure variation (PPV) has been shown to predict preload fluid responsiveness in mechanically ventilated patients [1]. Inadequate anesthetic agents have dose-dependent hemodynamic and direct myocardial contractility effects. The aim of this study was to compare the behavior of PPV under desflurane, sevoflurane and isoflurane anesthesia.

Methods

Twenty-four anesthetized and mechanically ventilated pigs were randomly assigned into three groups of eight animals: desflurane (DESF), sevoflurane (SEVO) and isoflurane (ISO). Static hemodynamic parameters and PPV, measured by pulmonary artery and femoral arterial catheters, were assessed at baseline (T1) using 1 MAC of the volatile agent; T2 (1.25 MAC); T3 (1 MAC) and T4 (1.0 MAC of the volatile agent) and the diagnostic category (P = 0.020). CCE was not significant and was not included in the model. See Table 1.

Conclusions

We demonstrate that CCE registered in the first 24 hours from admission is not a good prognostic index. The differences of CCE value between patients with good and negative outcome was not statistically significant. This result may suggest that a low CCE value in 24 hours from admission does not necessarily mean a bad outcome but, on the contrary, can be successfully improved by a therapeutic approach. It will be interesting to study whether there are some correspondences between CCE variations and modifications of the clinical conditions of the patients that may predict a positive or negative outcome.

Evaluation of pulse pressure variation with different inhaled concentrations of desflurane, sevoflurane and isoflurane in pigs

AH Oshiro, DT Fantoni, DA Otsuki, KT Rosa, JD Auler Jr
Faculdade de Medicina da universidade de São Paulo, Brazil

Introduction

Pulse pressure variation (PPV) has been shown to predict preload fluid responsiveness in mechanically ventilated patients [1]. Inadequate anesthetic agents have dose-dependent hemodynamic and direct myocardial contractility effects. The aim of this study was to compare the behavior of PPV under desflurane, sevoflurane and isoflurane anesthesia.

Methods

Twenty-four anesthetized and mechanically ventilated pigs were randomly assigned into three groups of eight animals: desflurane (DESF), sevoflurane (SEVO) and isoflurane (ISO). Static hemodynamic parameters and PPV, measured by pulmonary artery and femoral arterial catheters, were assessed at baseline (T1) using 1 MAC of the volatile agent; T2 (1.25 MAC); T3 (1 MAC) and T4 (1 MAC associated with a 30% hemorraghe of estimated average volemia). Two-way ANOVA and Tukey test were used for statistical analysis (P <0.05).

Results

At T2 there was an increase in PPV in all groups but not statistically significant compared with T1 or among groups. At T4 the increase in PPV was significant compared with basal values in the three groups: DESF (11 ± 4 vs. 7 ± 2%, P <0.001); SEVO (15 ± 5 vs. 6 ± 2%, P <0.001) and ISO (14 ± 5 vs. 7 ± 3%, P <0.001). No statistical difference between groups was found for PPV. Mean arterial pressure (MAP) decreased after 25% increment of MAC (T2) and after hemorrhage. At T4, MAP decreased significantly lower than basal values (T1) in groups DESF (P <0.001), SEVO (P <0.001) and ISO (P <0.001). Cardiac index (CI) decreased in T2 compared with T1: DESF (3.6 ± 0.6 vs. 2.9 ± 0.5 l/min/m², P <0.001), SEVO (4.0 ± 0.1 vs. 3.1 ± 0.4 l/min/m², P <0.001) and ISO (4.2 ± 0.1 vs. 3.6 ± 0.9, P <0.001). The CI drop after hemorrhage showed no statistical difference when compared with T1.

Conclusions

PPV behaved similarly with different inhaled anesthetics. Although PPV did not reflect the hemodynamic depression of incrementing MAC values, it increased after bleeding 30% of estimated volemia.

E/Ea ratio could not predict fluid response in ICU mechanically ventilated patients

J Cousby1, A Mari1, P Marty2, B Riu1, P Sanchez1, O Mathe1, J Ruiz2, S Silva1, F Vallée1, M Génestal1, O Fourcade1
1Reanimation polyvalente CHU Purpan, Toulouse, France; 2CHU Purpan, Toulouse, France

Introduction

Transtheracic echocardiography (TTE) is now widely used in the ICU to assess hemodynamic status. Combined mitral index measured by TTE, as the mitral Doppler inflow E wave velocity to annular tissue Doppler E wave velocity ratio (E/Ea), is a reliable diastolic indicator in cardiological patients. In ICU, E/Ea has only been investigated as a pulmonary arterial occlusion pressure surrogate which poorly reflects fluid responsiveness (FR). Therefore, the aim of this study was to evaluate the reliability of E/Ea to FR in the setting of ICU ventilated patients.

Methods

We carried out a TTE prospective observational study in mechanically ventilated patients receiving fluid challenge for circulatory failure. Complete TTE examination involving stroke volume (SV) estimation, mitral and tissue Doppler measurements (E, A, Ea, Aa velocities) were performed at end-expiratory time, before and after a 500 ml saline solution over 15 minutes of fluid challenge. A positive hemodynamic response was defined as a 15% minimal increment of SV. General characteristics, mitral parameters and combined index (E/A and E/Ea) were compared between responders (R) and nonresponders (NR) (using Student t test or chi-square test, ROC analysis and LHR method).

Results

Ninety-four case-mix patients were enrolled: 43 R and 51 NR, with similar baseline characteristics. LV ejection fraction was: altered (<50%) n = 24, or preserved (>50%) n = 69, with no difference (R vs. NR, E/Ea values before fluid loading were not statistically different between R and non-NR for which we observed a large overlap (7.4 ± 2.4 vs. 8.4 ± 3.1 R vs. NR). After fluid loading, the results were similar when considering the population with baseline under the median value; that is, E/Ea <8.28 R versus 24 NR, E/Ea = 6.0 ± 1.5 versus 5.6 ± 1.5 R versus NR, P = 0.28. The E/A index was significantly lower in R (1.1 ± 0.4 vs. 1.3 ± 0.4; P <0.01) but poorly predicted FR: ROC curve AUC = 0.64 (0.54 to 0.74), best cut-off: 0.8 (LHR+ 3.1; LHR− 0.7). Extreme values were predictive in our population: R was likely with E/A <0.6 (Sp 100%, LHR+ >5) and unlikely with E/A >1.8 (Se 100%, LHR− <0.2).

Conclusions

The E/Ea ratio is not statistically different between responders and nonresponders in the ICU and no low discriminant threshold value of E/Ea could identify patients likely to respond to fluid expansion. While E/A is statistically significant, only extreme values could be clinically relevant (<0.6 or >1.8).

Comparison between MostCare and echocardiography for cardiac output estimation in trauma patients

E Falciani, F Franchi, R Silvestri, L Cubattoli, P Mongelli, E Casadei, P Giomarelli, S Scolletta

University of Siena, Italy

Introduction

The reliability of the pulse contour methods (PCMs) in cardiac output (CO) monitoring has been questioned when changes in arterial tone occur spontaneously (for example, pain, hypovolemia) or after a therapeutic intervention (for example, nitroglycerin, nor-epinephrine). The purpose of this study was to compare the CO values assessed with the MostCare system (Vygon, Padova, Italy) (MC-CCO) with those obtained with transthoracic echocardiography ( ESAOTE Mylab 70, Genova, Italy) (TTE-CCO) in trauma patients treated with norepinephrine.

Methods

Twenty-seven adult trauma patients admitted to a seven-bed ICU and requiring norepinephrine infusion were enrolled in the study. Inclusion criteria were: age >18, no aortic valve pathologies, sinus rhythm. TTE-CCO and MC-CCO were evaluated simultaneously.
at two different stable hemodynamic states: baseline (T1), and after raising mean arterial pressure to 90 mmHg by starting norepinephrine infusion (T2). The MostCare system, an uncalibrated PCM, was connected directly to the main monitor of the patient for the analysis of the radial artery pressure wave. Bland–Altman and linear regression analyses were performed.

Results Fifty-four paired CO values were obtained; TTE-CO values ranged from 2.9 to 6.8 l/minute and MC-CO from 2.8 to 6.9 l/minute. At T1 the mean bias between the techniques was −0.07 l/minute (2SD = 0.69 l/minute), with a percentage of error (PE) of 15% and R = 0.9; at T2 the mean bias between the techniques was −0.13 l/minute (2SD = 0.83 l/minute), PE was 17% and R = 0.88. Overall, a good correlation between TTE-CO and MC-CO was observed (R = 0.9, P < 0.01), with a mean bias of −0.10 l/minute (2SD = 0.76 l/minute), 95% limits of agreement of −0.86 to 0.66 l/minute, and a PE of 16%. Mean arterial pressure was 82.2 ± 11.6 mmHg at T1 and 94.1 ± 3.8 mmHg at T2 (P < 0.05). Heart rate did not change significantly from T1 to T2 (78.9 ± 13.6 bpm vs. 78.3 ± 18.7 bpm, respectively, P > 0.05). Mean dosage of norepinephrine was 0.22 ± 0.1 μg/kg/minute (range 0.1 to 0.65 μg/kg/minute).

Conclusions MC-CO values showed a good agreement with TTE-CO at the two different hemodynamic states of trauma patients. Under the studied conditions, the reliability of the MostCare system seemed not to be affected by the changes in vascular tone induced by norepinephrine infusion.

PS9 Comparison of stroke volume changes of LiDCO™plus and Flotrac™ during postoperative hemodynamic optimization

MG Costa, T Cecconset, P Chiarandini, S Buttera, L Pompei, G Della Rocca
University of Udine, Italy

Introduction Postoperative hemodynamic optimization (PHO) [1] can be performed with mini invasive devices that showed different level of agreement when compared with the pulmonary artery catheter [2]. The aim of the study was to evaluate the concordance on stroke volume index changes (ΔSVI) obtained from calibrated (LiDCO™plus) and uncalibrated pulse contour (Vigileo™) devices in a surgical patient cohort during early PHO.

Methods The setting was a prospective study in the ICU of a university hospital. Twenty-seven patients undergoing abdominal surgery and a PHO protocol were enrolled. We compared the paired SVI values obtained by the two devices 30 seconds before and 2 minutes after ending a volume challenge (VC) of HES 130/0.4 (3 ml/kg). In the protocol a SVI increase >5% after volume expansion defined a responder patient. Concordance of the response in terms of SVI direction of changes detected by each monitor (Vigileo-SVI and LiDCO-SVI) was analysed as proposed by Critchley and colleagues [3]. A Bland–Altman plot was used to define bias and accuracy between SVI obtained from the studied devices.

Results The mean bias between LiDCO-SVI and Vigileo-SVI was 1.16 ml/m² with SD of 12.51 ml/m². The 95% limit of agreement was from −23.36 to 25.68 ml/m². During all of the study period 47 VCs were administered. In eight out of 27 patients also 13 dobutamine tests were performed. The two devices showed the same direction of changes in 78% of the cases. In detail, they showed the same direction in 83% of cases after VC and in 62% of cases after dobutamine administration. Among the concordant data pairs, the devices agreed in 81% of cases to define responder and nonresponder and in 82% and 75% of cases after VC and dobutamine tests, respectively.

Conclusions LiDCO™plus and Vigileo™ tests during a PHO protocol identified the same direction of changes in 78% of cases. Among this 78%, the devices agreed both in 81% of cases to define responder and nonresponder.

P60 A clinical pilot study to evaluate the correlation between pulse wave velocity and cardiac output during elective surgery

D Cain, S Harris
University College Hospital, London, UK

Introduction Pulse wave velocity (PWV) is defined as the speed of conduction of a pressure wave generated by cardiac systole through the arterial tree. It may be non-invasively estimated from the pulse transit time that is measured as the interval between the R wave on an electrocardiogram and first inflexion point of the paired plethysmographic wave recorded from a finger pulse oximeter [1]. Within a simple two-component Windkessel model of the arterial system, PWV is proportional to the square root of arterial elastance [2]. Elastance is defined as the ratio of pulse pressure (PP) to stroke volume (SV). PWV might therefore provide a non-invasive estimate of cardiac output.

Methods Adult patients undergoing major elective surgery were eligible. PWV was recorded using HypnoPP (Nelco Puritan-Bennet). Invasive arterial blood pressure measurements were preferred when available. Stroke volume was measured via ODM (Deltex Ohmeda). Values were recorded every 5 minutes, smoothed (median of five consecutive values) and converted to the centimetre gram second second system. SV was derived from PWV: SVPWV x PP⁻¹.

Results Eleven patients (aged 45 to 74 years; five men, six women) were enrolled. Data are presented as (mean, SD). PWV was successfully measured on 287 occasions (324 cm²/second, 48.3). SVPWV was calculated (62.4 ml, 18.3). SVODM values were (88.7, 4.86). Individual plots of SVPWV and paired SVODM were generated for each patient (Figure 1).

Conclusions Estimated SVPWV values were within a clinically expected range; however, visual inspection of the plots demonstrated no relationship between SVPWV and gold standard SVODM. Furthermore, there was no relationship between raw PWV data and SVODM. It is possible that PWV recordings were unreliable. The limited range of SVODM will have compressed our data, making any relationship less evident. We conclude SVPWV is not an accurate estimate of SVODM.

Comparison of cardiac index: LiDCOrapid and PiCCOplus in the ICU

P Brass1, E Mills1, J Latza2, J Peters3, E Berendes1
1Helios Klinikum, Krefeld, Germany; 2LiDCO Ltd, London, UK; 3Klinikum Duisburg, Germany

Introduction This study aims to compare two arterial pressure waveform monitors: the nomogram scaled LiDCOrapid (LiDCO Ltd, London, UK) with the calibrated PiCCOplus, (Pulsion, Munich, Germany), to determine agreement for cardiac index (CI) measurement and trending during positional changes of passive leg raise test (PLRT) and volume expansion in the ICU.

Methods We recruited 20 patients who had undergone major abdominal or neurosurgery and 10 patients in the SICU with progressive circulatory instability. The femoral artery was cannulated to obtain the arterial blood pressure waveform. Simultaneous measurements were made at four time points, M1 to M4: (M1) baseline, (M2) after PLRT, (M3) baseline (M4), after 500 ml Tetraspan® 6% over 10 minutes via pressure infusion. The PiCCO was calibrated via transpulmonary thermodilution at each time point.

Results Data were collected from 30 patients, age 31 to 90, ASA 2 (2), ASA 3 (24) or ASA 4 (4), BSA 1.54 to 2.52 m². Patients were ventilated with at least 6 ml/kg IBW, and RR of 10 to 15/minute. LiDCO identified 15 patients as responders (50%) and LiDCO identified 18 patients as responders (60%) to the fluid challenge, both within the normal range of established studies. ROC curve analysis results are shown in Figure 1. Concordance was calculated as 97.8% overall agreement (44/45) for ΔCI on changes at timepoints M2 to M4 relative to baseline (M1). Concordance was calculated as 97.8% overall agreement (44/45) for ΔCI >5%. Regression analysis found a high degree of correlation ($r^2 = 0.86$ to 0.92) and all intercepts equal to 0.

Conclusions In a heterogeneous patient population, LiDCOrapid CI values are in agreement with PiCCO CI values according to the accepted standard of ±30% with minimal bias. Trending analysis showed excellent concordance of 97.8%, which meets the recently proposed standard of >90% [1]. The LiDCOrapid is a valid measure of CI and trends in CI. It is easier to set up, does not require central venous access, is independent of the arterial site and can be used both intraoperatively in the OR and in the ICU.

Pressure recording analytical method versus PiCCO in hemodynamic unstable patients
A Donati, S Loggi, A Carsetti, MR Lombrano, L Botticelli, A Valentini, V Fiori, R Domizi, C Scorcella, P Pelia
Università Politecnica delle Marche, Ancona, Italy

Introduction Hemodynamic monitoring is important for diagnosis and therapy of critically ill patients. Thermodilution is now the gold standard method; however, it cannot be used routinely since it is very invasive. We investigated the agreement between the cardiac index (CI) obtained by mini-invasive monitor MostCare, based on the pressure recording analytical method (PRAM), and by PiCCO thermodilution in hemodynamic unstable patients.

Methods We performed a prospective clinical study at our university hospital ICU. Twenty adult patients with hemodynamic instability were enrolled. All patients were sedated and mechanically ventilated with intermittent positive pressure ventilation. The MostCare and PiCCO systems were connected to each patient by a catheter inserted into the femoral artery. For each patient three measurements of CI were simultaneously carried out and the mean was considered for statistical analysis.

Results We enrolled 10 severe sepsis/septic shock, four interstitial pneumonia, three COPD, one subarachnoid hemorrhage, one abdominal compartment syndrome, and one polytrauma. The age range
was 46.7%. Among the studied indices, only ΔSVI-PLR was significantly different in responders and nonresponders (26.9 vs. 1.9, \( P < 0.001 \)). Three indices, ΔSVI-PLR, ΔCO-PLR and ΔCI-PLR, were significantly correlated with increase in SVI after fluids (\( \rho = 0.854 (P < 0.001), 0.727 (P = 0.002), 0.710 (P = 0.003) \)). ΔSVI-PLR correctly predicted responders state in all cases with a threshold of 9.1% (sensitivity 100%, specificity 100%, area under the ROC curve (AUC) 1.00 (\( P < 0.001 \) 95% CI = 1.00 to 1.00)). The other indices had values of AUC not significantly different from 0.5.

**Conclusions** The ΔSVI-PLR, measured with the LiDCO system, is a very reliable predictor of fluid responsiveness in a population of ICU patients in shock, including patients with spontaneous breathing activity and arrhythmias.

**Reference**
to use ΔCVP and ΔMAP to guide fluid therapy, despite an accumulation of evidence to suggest that filling pressures are inadequate predictors of fluid status and responsiveness. Recent interest has been directed towards dynamic measures of cardiac filling such as SVV, SPV, PPV and Δdown and Δpeak. A number of large multicentre trials are underway using the LiDCOrapid. There is, however, little information about the utility of this device or, indeed, any other minimally-invasive cardiac output monitor in the prediction of fluid responsiveness.

Methods The haemodynamic parameters of 70 high-risk patients (mean age 71 ± 11.3, median ASA 3) undergoing major vascular surgery (mean duration 4 ± 1.1 hours) were evaluated retrospectively using LiDCOViewPro. All patients underwent standard induction and maintenance of anaesthesia, with propofol/remifentanil TIVA and IPPV (tidal volume ≥7 ml/kg) via a supraglottic airway. Monitoring included BIS, NICU and LiDCOrapid. Fluids were administered according to clinical assessment of need and available haemodynamic parameters. Only fluid boluses given in the absence of HRV >10%, brisk ongoing blood loss and of volume ≥250 ml were included in the evaluation. Positive response to a fluid challenge was defined as ΔSVI ≥10%. Statistical analysis was performed using SPSS 17.0.

Results Thirty-two out of 43 valid fluid challenges were positive (74.4%). The correlation coefficients between the baseline SVV, SPV and PPV measurements were 0.27 (P = 0.08), –0.01 and 0.18 (nonsignificant). The AUROC were 0.75 (95% CI = 0.57 to 0.93), 0.587 (0.36 to 0.82) and 0.67 (0.48 to 0.86), respectively. The best cut-off value for SVV using Youden’s index was 13.5%, with J = 0.48. The positive likelihood ratio was 2.74 and the negative likelihood ratio 0.34, with diagnostic odds ratio 8.06 at this level.

Conclusions It has been reported that only 50% of critically unwell patients respond to fluid challenge, compared with 74.4% in this intraoperative study of noncardiac surgical patients. The SVV was an adequate predictor of fluid responsiveness. The diagnostic threshold of 13.5% was consistent with previous studies.

P67 Pressure recording analytical method for cardiac output monitoring in children with congenital heart disease
Z Ricci
Bambino Gesù Hospital, Rome, Italy

Introduction The Swan–Ganz catheter cannot be considered the gold standard in the pediatric setting for cardiac output (CO) monitoring, due to the unavailability of pulmonary artery catheters (PACs) of adequate size for children of all ages and weights and due to peculiar cardiovascular anatomies of some children with congenital heart disease (CHD). The pressure recording analytical method (PRAM) is designed for arterial pressure-derived continuous CO measurement and it does not need any starting calibration, central venous catheterization, or adjustments based on experimental data. The aim of this study was to validate PRAM in a cohort of children with CHD.

Methods An observational study was conducted on 25 children with CHD who underwent diagnostic cardiac catheterization (seven corrected tetralogy of Fallot, three corrected complete atrioventricular canal, 10 corrected transposition of great arteries and five dilative cardiomyopathy), aiming to compare CO measurement by PRAM and by PAC. Enrollment criteria were: biventricular anatomy in the absence of intracardiac shunts, weight <20 kg, prescheduled need for Swan–Ganz measurement of CO and arterial cannulation. The Swan–Ganz CO value considered in our study was the average measure deriving from three thermodilution boluses. The corresponding PRAM CO value was the average measure of those picked simultaneously with the three thermodilution boluses. All patients were anesthetized (2% inhaled sevoflurane and intravenous remifentanil at 0.1 μg/kg/minute) and mechanically ventilated.

Results The median patient age was 4 years (IQR 2.5 to 6) and median weight was 13 kg (IQR 9 to 17). A significant linear correlation between PRAM and Swan–Ganz measurements was found (P <0.0001). In particular, Bland–Altman analysis showed a bias of 0.2 l/minute (SD 0.47) and 95% limits of agreement from –0.7 to 0.9 l/minute: the performance of this method seemed optimally coupled with PAC measurements when CO ranged from 1 to 2 l/minute whereas for higher COs the difference between the two methods increased. However, only three measurements fell out of the limits of agreement and all were at CO levels oues over 2.5 l/minute (more rarely observed in pediatric patients with CHD). Age, weight, heart rate and cardiac diagnosis were not significantly correlated with PRAM to Swan–Ganz difference. Conclusions PRAM may be considered an accurate method in pediatric patients with CHD: these results should be validated in the pediatric ICU, also verifying PRAM’s impact on clinical decision-making.
hypovolemia induced by lower body negative pressure (LBNP) has never been studied.

**Methods** The PI was measured in 24 healthy volunteers during the LBNP test using the pulse oximetry Masimo SET Perfusion Index. The LBNP protocol consisted of 5-minute baseline measurements in the supine position followed by stepwise increases of negative pressure from 0 to –20, –40, –60, –80 and 0 mmHg. HR, BP, and cardiac output were recorded during all of the procedure using a Finometer Blood Pressure Monitor.

**Results** Subjects were all male (age mean: 23 ± 6). Figure 1 shows that in all subjects the PI decreased significantly by 40% (P = 0.03) during the first –20 mmHg, and kept in this range during the whole experiment. SV decreased significantly by 20% at –40 mmHg. The HR increased significantly by 15% at –40 mmHg. SV and HR changes were proportional to the level of negative pressure in the chamber. No significant changes in BP and CO were observed.

**Conclusions** PI is a sensitive indicator of acute hemodynamic responses to the LBNP-induced central hypovolemia. In addition, it could detect hypovolemia earlier than the 20% decrease in stroke volume.

**P70**

Carotid blood flow is correlated with cardiac output but not with arterial blood pressure in porcine fecal peritonitis

T Correa, A Reintam Blaser, J Takala, S Djafarzadeh, M Vuda, M Dünser, S Mathias Jakob

University Hospital Bern – Inselspital and University of Bern, Switzerland

**Introduction** Cerebral blood flow may be impaired in sepsis [1]. The objective of this study is to evaluate whether and how carotid blood flow (CBF) depends on cardiac output and mean arterial blood pressure in abdominal sepsis.

**Methods** Thirty-two anesthetized pigs (weight: 40.3 ± 3.7 kg (mean ± SD)) were randomly assigned (n = 8 per group) to a nonseptic control group (CG) or one of three groups in which resuscitation was initiated 6, 12 or 24 hours after induction of fecal peritonitis (instillation of 2 g/kg autologous feces). In the treatment groups, resuscitation was performed for 48 hours according to the Surviving Sepsis Campaign. The CG was observed for 72 hours. CBF (carotid artery; ultrasound Doppler flow), cardiac output (intermittent thermodilution) and arterial blood pressure (MAP) were measured at 6-hour intervals. Pearson correlation were performed between CBF index (CBFI) and cardiac index (CI) and MAP, respectively, both in individual animals and in pooled septic and control groups.

**Results** Altogether 227 measurements were obtained during sepsis and 128 in controls. In septic animals, CBFI and CI (r = 0.53, P <0.001; Figure 1) but not CBFI and MAP correlated (Figure 2). In controls, CBFI and MAP correlated weakly and inversely (r = –0.246, P = 0.005; data not shown).

**Conclusions** Under the experimental conditions, increasing systemic blood flow but not blood pressure has the potential to improve CBF.

**P71**

Afterload-related cardiac performance: a hemodynamic parameter with prognostic relevance in patients with sepsis in the Emergency Department

J Wilhelm, S Hettwer, M Schürmann, S Bagger, F Gerhardt, S Mundt, S Muschick, J Zimmermann, H Ebelt, K Werdan

Martin-Luther-University, Halle (Saale), Germany

**Introduction** Afterload-related cardiac performance (ACP) was developed to describe cardiac function in patients with sepsis, when cardiac output (CO) is increased due to a decline in systemic vascular resistance (SVR). We now studied the prognostic relevance of ACP in comparison with the cardiac index (CI) and cardiac power index (CPI) in patients at a very early stage of community-acquired sepsis (CAS) in the Emergency Department.
Methods In patients ≥18 years admitted to our Emergency Department with CAS (infection and ≥2 SIRS criteria), CI, CPI, and ACP were measured either non-invasively (TaskForce-Monitor; CNSystems, Austria) or invasively. ACP was calculated as ACP = 100 x CO / (560.68 x SVR–0.64). Cardiac function was graded into normal (>80%), slightly (61 to 80%), moderately (41 to 60%) or severely impaired (≤40%).

Results Of 137 patients studied, 48.2% had sepsis, 33.6% severe sepsis, and 18.2% septic shock. Overall 30-day mortality was 10.9%. On admission ACP was 86.7 ± 27.7% in severe sepsis and 85.5 ± 25.8% in septic shock, significantly lower than in patients with sepsis without signs of organ dysfunctions (98.6 ± 22.3%, P <0.01), whereas no differences were observed for CI or CPI, respectively. In severe sepsis or septic shock, impairment of ACP was observed more often than in sepsis (Figure 1A). Nonsurvivors showed a significantly depressed ACP already on admission and after 72 hours (Figure 1B), whereas CPI differed only after 72 hours between survivors and nonsurvivors (0.52 ± 0.18 vs. 0.32 ± 0.17, P<0.05) and CI showed no differences in this regard. ACP correlated better with APACHE II score (r = –0.371, P<0.001) than CPI (r = –0.330, P<0.001) or CI (r = –0.220, P<0.001). Only ACP correlated with serum levels of procalcitonin (r = 0.224, P<0.001) and IL-6 (r = –0.173, P<0.05).

Conclusions Taken together, only the parameter ACP but not CI nor CPI is able to detect an early impairment of cardiac function in patients with CAS and provides prognostic information on admission.

Evaluation of a continuous non-invasive arterial blood pressure monitoring device in comparison with an arterial blood pressure measurement in the ICU
K Smolle1, M Schmid2
1University Hospital, Graz, Austria; 2Department of Internal Medicine, Graz, Austria

Introduction Due to a lower risk of complications, non-invasive monitoring methods gain importance. Measuring arterial blood pressure belongs to the standard hemodynamic monitoring. A newly developed continuous non-invasive arterial blood pressure (CNAP) measurement method is available and has been validated perioperatively [1]. We compared the CNAP monitoring device with invasive arterial blood pressure measurement (IBP) as the gold standard in critically ill patients.

Methods We performed a prospective study on 49 critically ill patients at a medical ICU. All patients were sedated and mechanically ventilated (BIPAP, tidal volume 7 to 8 ml/kg ideal body weight). Furthermore, all patients were under vasopressor therapy. CNAP was applied on two fingers of the hand contralateral to the invasive arterial blood pressure catheter in the A. radialis. All measurements were digitally recorded with a sample frequency of 100 Hz, every pulse beat was automatically identified by an algorithm [2] and subsequently artefacts were removed from the datasets. The average recording time in each patient was 163 minutes (±37 minutes/patient).

Results In total we analysed 500,000 beats. Overall we observed a bias in mean pressure of –7.49 mmHg with a standard deviation of 10.90 mmHg. The Bland–Altman plot (Figure 1) showed a uniform distribution of the variances over all measured blood pressure values and a good agreement of the mean blood pressure between CNAP and IBP. When analysing the data of each individual patient, larger differences were found. The bias ranged from 0.28 to 23.9 mmHg (median = –6.6 mmHg), with a standard deviation between 2.0 and 14.9 mmHg (median = 5.8 mmHg).

Conclusions In our study we detected a good overall agreement between CNAP and IBP. The future perspective of this study is to investigate whether the continuous non-invasive blood pressure waveform is suitable for deriving further hemodynamic parameters of fluid responsiveness.

Brachial cuff measurements for fluid responsiveness prediction in the critically ill

K Lakhal1, S Ehrmann1, D Benzekri-Lefèvre1, I Runge1, A Legras2, E Mercier2, PF Dequindre3, M Wolff4, B Régnier4, T Boulain3

Introduction

The passive leg raising maneuver (PLR) with concomitant measurement of invasive arterial pressure (AP) or cardiac output (CO) changes are used to test volume responsiveness. The initial hemodynamic evaluation of shocked patients often relies on the sole non-invasive measurement of AP. We assessed the performance of PLR-induced changes in oscillometric measurements of systolic, mean and pulse AP (ΔplrSAP, ΔplrMAP and ΔplrPP).

Methods

CO and AP measurements were performed before/during PLR and then after 500 ml volume expansion.

Results

In 112 patients, the area under the ROC curve (AUC) of ΔplrSAP was 0.75 (0.66 to 0.83). When ΔplrSAP >17%, the positive likelihood ratio (LHR) was 26 (18 to 38). Non-invasive ΔplrPP and non-invasive ΔplrMAP were associated with an AUC of 0.70 (0.61 to 0.79) and 0.69 (0.59 to 0.77), respectively. If PLR induced change in central venous pressure (CVP) it was ≥2 mmHg (n = 60), suggesting that PLR actually changed the cardiac preload, AUC of ΔplrSAP was 0.90 (0.80 to 0.97). In these patients, ΔplrSAP >9% was associated with a positive and negative LHR of 5.7 (4.6 to 6.8) and 0.07 (0.009 to 0.5), respectively. See Figure 1.

Conclusions

Regardless of CVP (blind PLR), ΔplrSAP >17% reliably identified responders. CVP-guided PLR allowed ΔplrSAP to perform better in the case of sufficient change in preload during PLR.

Validation of non-invasive hemodynamic monitoring with Nexfin in critically ill patients

K Van de Vijver, A Verstraeten, C Gillebert, U Maniewski, M Gabrovska, D Viskens, N Van Regenmortel, I De laet, K Schoonheydt, H Dits, M Malbrain

Reference

Methods

A prospective study in 45 patients (43 mechanically ventilated, 32 male). Age 57.6 ± 19.4, BMI 25.3 ± 4.4, SAPS II 51.5 ± 16.9, APACHE II 25.3 ± 10.3 and SOFA score 9.4 ± 3.3. In an 8-hour period, simultaneous CCO and NexCO measurements were obtained every 2 hours while simultaneous TDCO and NexCO were obtained every 4 hours. The CCO and NexCO values were recorded within 5 minutes before TDCO was determined. Statistical analysis was performed using Pearson correlation and Bland–Altman analysis.

Results

In total, 585 CO values were obtained: 225 paired CCO–NexCO; 135 paired CCO–TDCO and 135 NexCO–TDCO. Thirty-five patients received norepinephrine at a dose of 0.2 ± 0.2 μg/kg/minute (range 0.02 to 1). TDCO values ranged from 2.4 to 14.9 l/minute (mean 6.6 ± 2.2), CCO ranged from 1.8 to 15.6 l/minute (6.4 ± 2.3) and NexCO from 0.8 to 14.9 l/minute (6.1 ± 2.3). The Pearson correlation coefficient comparing NexCO with TDCO and CCO was similar with an R² of 0.68 and 0.71 respectively. Bland–Altman analysis comparing NexCO with TDCO revealed a mean bias ± 2SD (limits of agreement (LA)) of 0.4 ± 2.32 l/minute (with 36% error) while analysis of NexCO versus CCO showed a bias (± LA) of 0.2 ± 2.32 l/minute (37% error). TDCO was highly correlated with CCO (R² = 0.95) with bias 0.2 ± 0.86 (% error 13.3).

Reference

The MAP values obtained ranged from 43 to 140 mmHg (83 ± 17) for PiCCO, and from 44 to 131 (83 ± 17) for Nexfin. The MAP obtained with Nexfin correlated well with invasive MAP via PiCCO2 (R² = 0.89) with a bias (± LA) of 2.3 ± 12.4% (p error 14.7).

Conclusions These preliminary results indicate that in unstable critically ill patients CO and MAP can be reliably monitored non-invasively with Nexfin technology. Although TPTD remains a gold standard for the measurement of CO in ICU patients, Nexfin non-invasive monitoring may provide useful information in the emergency or operating room when an arterial or CVL is not available.

Pleth Variability Index predicts fluid responsiveness in critically ill patients
H Nanadourmgar, TL Loupeuc, DF Frasca, FP Pettipas, LL Laakri, DB Baudouin, OM Mimoz
CHU Poitiers, France

Introduction In patients with acute circulatory failure related to sepsis or hypovolemia, volume expansion is used as first-line therapy in an attempt to improve cardiac output. Dynamic indices based on cardiopulmonary interactions and variation in left ventricular stroke volume like respiratory variations in arterial pulse pressure (ΔPP) are able to predict response to fluid loading in mechanically ventilated patients. The Pleth Variability Index (PVI) (Masimo® Corp., Irvine, CA, USA) is a new non-invasive technique based on perfusion index (PI) variations during the respiratory cycle in mechanically ventilated patients. The objective of the study is to investigate whether PVI, a non-invasive and continuous tool, can predict fluid responsiveness in mechanically ventilated patients with circulatory insufficiency.

Methods A prospective study in a surgical ICU of a university hospital. Forty mechanically ventilated patients with circulatory insufficiency were included in whom volume expansion was planned by the attending physician. Exclusion criteria included spontaneous respiratory activity; cardiac arrhythmia; known intracardiac shunt; severe hypoxemia (PaO₂/FIO₂ < 100 mmHg); contraindication for passive leg raising (PLR); altered left ventricular ejection fraction; hemodynamic instability during the procedure. We performed fluid challenge with 500 ml of 130/0.4 hydroxyethylstarch if ΔPP ≥ 13% or with PLR otherwise. PVI, ΔPP, and cardiac output (CO) estimated by echocardiography were recorded before and after fluid challenge. Fluid responsiveness was defined as an increase in CO ≥ 15%.

Results Twenty-one patients were responders and 19 were non-responders. Median (interquartile range) PVI (26% (20 to 34%) vs. 10% (9 to 14%)) and ΔPP (20% (15 to 29%) vs. 5% (3 to 7%)) values at baseline were significantly higher in responders than in non-responders. A PVI threshold value of 17% allowed discrimination between responders and non-responders with a sensitivity of 95% (95% CI = 74 to 100%) and a specificity of 91% (95% CI = 70 to 99%). PVI at baseline correlated (r = 0.72; p < 0.0001) with percentage changes in CO (ΔCO) induced by fluid challenge, suggesting the higher PVI at baseline, the higher ΔCO after volume expansion.

Conclusions PVI can predict fluid responsiveness non-invasively in ICU patients under mechanical ventilation.

Dynamics of peripheral perfusion parameters in elective coronary artery bypass graft patients
M Van Gennip, J Boezmauizen, A Pinto Lima, D Gommers, J Bakker, J Van Bommel
Erasmus MC, Rotterdam, the Netherlands

Introduction Recent studies have suggested that microvascular perfusion impairment may play a role in the development of postoperative organ dysfunction in patients undergoing high-risk or cardiac surgery [1,2]. Postoperative monitoring of tissue perfusion parameters could therefore be used for early detection of tissue hypoperfusion and serve as an endpoint for resuscitation. For this purpose we measured regional and microvascular perfusion parameters in relation to systemic hemodynamics in patients undergoing open heart surgery.

Methods We observed 10 consecutive patients who underwent elective coronary artery bypass grafting with cardiopulmonary bypass during the immediate postoperative resuscitation in the ICU. Tissue perfusion was measured directly after admission and repeated after detubation, and consisted of sublingual SDF imaging, forearm Tskin-diff, finger peripheral perfusion index, finger capillary refill time (CRT) and thenar tissue oxygenation (StO₂). Cardiac output was measured with NICOM bioreactance.

Results CO (4.33 ± 1.63 vs. 5.37 ± 1.29) (P < 0.05) and central temperature (35.30 ± 0.24 vs. 36.56 ± 0.13) (P < 0.01) increased significantly. All tissue perfusion parameters (that is, SDF parameters (MFI ≥ 2.5; PPV ≥ 95%), StO₂ ≥ 80%, CRT ≥ 5 seconds, Tskin-diff ≤ 3 and PFI ≥ 1.4) were within the normal range at admission and did not change significantly until detubation. Even the central-to-toe temperature difference showed no significant difference or correlation between cardiac output and any other peripheral tissue perfusion parameter. The postoperative course was uncomplicated in all patients.

Conclusions In the postoperative period, peripheral and microvascular tissue perfusion parameters are not impaired in our CABG patients. Although from a small population, these data suggest that these parameters are not suitable for routine use as an extra hemodynamic resuscitation endpoint. This is in contrast with previous studies and might be explained by differences in study population or measurement interval.

Maintenance of arterial catheters with heparin: should we continue?
N Catorze, S Teixeira, J Cabrita, J Carreto, V Vieira, S Gonçalves, A Frade, J Martins
Centro Hospitalar Médico Tejo, Abrantes, Portugal

Introduction In ICU settings arterial catheters (AC) are used to manage critically ill patients. Maintaining the patency of these catheters is important for continuous hemodynamic evaluation and therapeutic adjustment. Heparinized solutions are used for this purpose although the increasing literature describes the use of saline solutions for the same reason. The authors compare the use of heparinized versus saline solution in the maintenance of ACs and to detect changes in AP, platelet count, and local inflammatory signs, in a double-blind randomized trial.

Methods During 80 days all ICU patients with ACs were randomized to receive heparinized solution (5 IU/ml) or saline solution. AC patency and functionality was compared in both every 6 hours, and aPTT, platelet count, and local inflammatory signs each 24 hours. Patients with thrombocytopenia, receiving anticoagulant or fibrinolytic treatment were excluded.

Results Two hundred days of ACs were observed in 49 patients, during which 110 days were with saline solutions and the rest were heparinized. Seven patients were excluded. The median duration of catheters in place was 4.4 days in the saline group and 3.8 days in the heparinized group. We recorded two ACs with local inflammatory signs in the heparinized group that were replaced in a septic context. One local hemorrhage and one AC obstruction were observed in the heparinized group versus no hemorrhage and three AC obstructions in the saline group. No other differences were obtained.
Conclusions The general use of heparin solution for AC maintenance does not seem to be adequate. In this study the comparison of the two populations revealed the same results despite the solution used. These results do not encourage the use of heparinized solutions because they do not have an effective cost/benefit relation and due to the potential iatrogenic problems described in the literature.

P79 Validation of continuous intragastric pressure measurement and correlation with intramucosal pH in a pig model
M Malbrain1, J De laet2, L Lu3, L Correa4, M Garcia4, G Castellanos3, 1ZNA Stuivenberg, Antwerp, Belgium; 2Neuron NPh, SA, Granada, Spain; 3Unidad Minimal Invasiva, Cazquets, Spain; 4Virgen de la Arrixaca University Hospital, Murcia, Spain

Introduction The aim of this study was the validation of continuous intragastric pressure (IGP) measurement and correlation with intramucosal pH (pHi) in a pig model of intra-abdominal hypertension (IAH).

Methods In 51 pigs, 611 paired IAP measurements were performed. IAP was measured at end-expiration using two different methods: the gold standard via an indwelling bladder catheter (IVP), and via a balloon-tipped nasogastric tube (IGP). During the same period 86 simultaneous pH and IGP measurements were performed in 40 pigs. The abdominal perfusion pressure (APP) was defined as mean arterial pressure (MAP) minus IAP. Statistical analysis was done via Pearson correlation and Bland–Altman analysis; values are mean ± SD unless stated otherwise.

Results Mean IGP was 22.3 ± 12.7 mmHg (range 0 to 43.1), and IVP was 22.9 ± 12.6 (0 to 48). There was a very good correlation between IGP and IVP. For the whole set of paired measurements (n = 611), IVP = 1.02 x IGP (R² = 0.96, P < 0.0001); and for the means per individual pig (n = 51), IVP = 1.03 x IGP (R² = 0.96, P < 0.0001). The analysis according to Bland–Altman analysis yielded: mean difference of IAP between the two monitors was 0.07 ± 2.71 mmHg (95% limits of agreement (LA) were –5 to 5.4 mmHg (% error of 21.5). Looking at the mean values in each individual animal mean IAP was 22 ± 9.4 (2.5 to 37.9), with a bias of 0.8 ± 1.9 (LA = –3 to 4.6) and a % error of 17.2. These intervals are small and reflect a good agreement between the two IAP methods. The mean pHi was 7.02 ± 0.28 (6.34 to 7.37) and correlated well with IGP (R² = 0.97, P < 0.0001). Analysis further showed that changes in pH correlated well with changes in pHi (R² = 0.66, P < 0.0001). The MAP was 48.3 ± 14 (3 to 138) and APP was 24.9 ± 17.4 (0.2 to 92). During 388 paired measurements APP correlated significantly with pHi (in a logarithmic fashion, R² = 0.18), the correlation was linear and even better in conditions when APP < 45 mmHg (n = 334): pHi = 0.016 x APP + 6.63 (R² = 0.55, P < 0.0001). Thus increased APP above 45 mmHg did not result in a further increase of pHi.

Conclusions We found a very good correlation between IGP and IVP. Measurement via the stomach has major advantages over the standard intravascular method: continuous measurement of IAP as a trend over time is possible and there is no interference with estimation of urine output. Moreover, APP is correlated with pH and pHi are inversely correlated.

P80 End-tidal carbon dioxide levels predict cardiac arrest
H Manyam, P Thigagarajah, G Patel, R French, M Balaam
Allegheny General Hospital, Pittsburgh, PA, USA

Introduction End-tidal carbon dioxide (CO₂) correlates with cardiac output during cardiopulmonary resuscitation (CPR) in cardiac arrest patients. Increasing CO₂ during CPR can also indicate the return of spontaneous circulation.

Methods CO₂ was continuously monitored and recorded every 4 hours in 43 patients who were intubated and on vasopressor medications.

Results Mean CO₂ values were significantly higher in normal patients when compared with those in patients who had a cardiac arrest (30.18 ± 4.93 vs. 17.45 ± 4.76; P < 0.001). CO₂ levels were significantly lower in cardiac arrest patients when compared with hypotensive patients 1, 2, 3, and 4 hours prior to a cardiac arrest (Table 1). CO₂ levels were significantly lower in cardiac arrest patients when compared with patients who were acutely withdrawn from care 1, 2, 3, and 4 hours prior to the event (see Table 2).

Conclusions CO₂ levels decrease prior to cardiac arrest and are significantly lower than prior to hypotensive or acute withdrawal of care events. Further study needs to be done on a larger scale to see whether these results hold true.

P81 NT-proBNP and troponin I in acute liver failure: do they predict cardiac dysfunction?
M McPhail1, VK Audimoolam1, W Bernal2, C Williams2, R Sherwood2, J Wendorf2, G Auzinger2
1Imperial College, London, UK; 2King’s College Hospital, London, UK

Introduction Distractive shock with high output cardiac failure is frequently seen in acute liver failure (ALF). A previous study suggested a high incidence of myocardial injury coupled with adverse outcome in this population [1]. Correlation of cardiac biomarkers with invasive hemodynamic parameters or results of echocardiographic studies has thus far not been performed.

Methods NT-proBNP (NT-proBNP) and troponin I (TI) were measured in ALF patients with shock within 48 hours after admission to a tertiary specialist ICU. Transpulmonary thermodilution cardiac output monitoring (PICCO) was performed in all patients. Values of cardiac index (CI), stroke volume index (SVI), global end diastolic index (GEDI) and markers of contractility – global ejection fraction (GEF) and cardiac function index (CFI) – as well as severity of illness scores were correlated with cardiac biomarker levels. Correlation was assessed using Pearson’s coefficient for normally distributed data.

Results Twenty-six ALF patients with a mean (SD) APACHE II score of 23 (4) and SOFA 15 (2) were assessed. NT-proBNP (median 715 [46 to 10, 484] pg/ml) and TI (median 0.28 [0 to 50] u/l) levels were both significantly elevated without any significant ECHO abnormalities and 24 patients required renal replacement therapy. Serum NT-proBNP correlated with serum lactate (correlation coefficient 0.61, P = 0.001) and Ti (0.63,
Clinical markers mean that their significance is unclear.

Temporal profile after bypass, the lack of correlation with IL-6 and clinical outcome variables. Conversely, peak IL-6 correlated with bypass time (P = 0.084) but not with CI (0.021, 0.92). CFI was correlated with GEF (0.55, P = 0.001) and lactate (0.53, P = 0.003). APACHE and SOFA did not correlate significantly with PICCO indices.

Conclusions: Levels of cardiac biomarkers are frequently elevated in ALF. We could not find any correlation of TI and NTproBNP with surrogate markers of cardiac function on invasive hemodynamic monitoring, or indeed significant abnormalities on ECHO.

Endothelial glycocalyx disruption after cardiac surgery in infants
V Shevard, S Tibby, H Bangalore, A Durward, I Murdoch
Evelina Children's Hospital, London, UK

Introduction
The endothelial glycocalyx (EGX) modulates vascular permeability and inflammation. It is disrupted by ischemia–reperfusion. We hypothesised that cardiopulmonary bypass would elevate markers of EGX shedding, which would be associated with increased postoperative inflammation.

Methods
A prospective cohort of 25 infants (median weight 5 kg) undergoing surgery for congenital heart disease. Blood temporal profiles of two markers of EGX disruption – heparan sulphate (HEP) and syndecan-1 (SYND) – were correlated with a biochemical marker of systemic inflammation (IL-6) and clinical outcome variables.

Results
Infants showed a dramatic rise in SYND, which peaked at the end of bypass, returning to baseline at 48 hours (Figure 1). The median (IQR) peak SYND levels were 144 ng/ml (113 to 190), representing a sixfold rise from baseline. A less pronounced rise was seen for HEP (median 22.5 μg/ml), which approximately doubled. Peak IL-6 occurred at 12 hours post bypass; median 118 pg/ml (44 to 217). Absolute peak values of both SYND and HEP correlated poorly with IL-6 and all clinical variables. Conversely, peak IL-6 correlated with bypass time (r = 0.53), length of ventilation (r = 0.69) and ICU stay (r = 0.58).

Conclusions
Although markers of EGX disruption show a reproducible temporal profile after bypass, the lack of correlation with IL-6 and clinical markers means that their significance is unclear.

Figure 1 (abstract P82). Syndecan-1 profile.
the first 14 days, lung function by PaO/FIO2 ratio and ventilation time. Between 2004 and 2006, standard colloid was HES (mainly 6% HES 130/0.4 (87%) and 10% HES 200/0.5). Between 2006 and 2008, standard colloid was changed to 4% gelatin (Gel). From 2008 until April 2010, patients received only crystalloids (Cry).

Results Groups were comparable at baseline concerning SAPS II and SOFA scores, age and renal function. Patients who received synthetic colloids more often met the criteria for AKI (Cry 58.4%, HES 70.6% P = 0.001, Gel 67.6% P = 0.012) or required RRT (Cry 27.8%, HES 34.2% P = 0.072, Gel 35.5% P = 0.031) than patients receiving only crystalloids. On day 3, liver enzymes peaked in both colloid groups but not in the crystalloid group (AST $\mu$mol/l, median (IQR): HES 2.2 (0.9 to 6.3) P = 0.001, Gel 1.7 (0.7 to 3.7) P = 0.158, Cry 1.0 (0.6 to 3.2); ALT: HES 1.1 (0.5 to 3.1) P = 0.003, Gel 0.9 (0.4 to 2.1) P = 0.109, Cry 0.6 (0.3 to 1.9). Bilirubin levels remained significantly elevated from day 0 to 14 in the HES and Gel groups. Median ventilation time (hours) was significantly longer in the HES and Gel groups: HES 214 (60 to 368) <0.001, Gel 146 (48 to 333) P = 0.002, Cry 105 (15 to 280). The PaO/FIO2 ratio and ICU or hospital mortality did not show significant differences.

Conclusions HES and gelatin may be associated with an increased risk of renal failure, impaired liver function and longer ventilation time in septic patients.

Intraoperative effectiveness of crystalloid and colloid volume substitution in patients undergoing elective major urological surgery by maintenance of the cardiac index within normal range
P Szurz, R Kula, J Maca, J Tichy, J Jahoda
Faculty Hospital Ostrava, Ostrava, Czech Republic

Introduction We compared intraoperative effectiveness of crystalloid and colloid substitution aimed to maintain the cardiac index (CI) within the normal range measured by transesophageal Doppler ultrasonography (TED) [1]. We also evaluated the frequency of postoperative complications, length of in-hospital stay and postoperative in-hospital mortality.

Methods One hundred and fifteen urological patients were enrolled into the prospective observational clinical study and then randomized into two groups. The first group was treated by volurometry based on crystalloids (Cry) n = 57, and the second group with colloids (Col) n = 58. High-risk surgery criteria were fulfilled in 47% patients in the Cry group and 45% in the Col group. Each patient obtained an esophageal Doppler probe (HemosonicTM100®; Arrow International, USA) after induction to general anesthesia and then hemodynamic optimization (fluid therapy with Ringer’s solution or HES 6% 130/0.4 and administration of vasoactive drugs) was started according to TED variables to keep the CI between 2.6 and 3.8 l/min/m². The supplementation of immeasurable fluid losses in the Col group was provided by infusion of Ringer’s solution 0.05 ml/kg/minute.

Results We observed high initial incidence of CI <2.6 l/min/m² after induction of general anesthesia (75%) in both groups. There were no significant differences in demographic characteristics, ASA classification, length of surgical procedure, estimated blood loss and CI during surgery. To maintain the CI we used significantly different amounts of crystalloids compared with colloids: means 5,182 ml versus 1,692 ml, respectively. The number of administered blood units was also higher in the Cry group versus the Col group: RBC 52 versus 19, P = 0.018, FFP 55 versus 16, P = 0.006, respectively. There was more G1 dysfunction in group Cry 31.6% versus 15.5% in the Col group, P = 0.031. The number of complications during 28 days on the ICU, overall in-hospital stay and mortality were not statistically significant.

Conclusions Crystalloids and colloids are effective in correction of intraoperative flow-related perfusion abnormalities. Different amounts of used crystalloids and colloids proved their unequal pharmacological characteristics (that is, distribution between compartments). The high amount of used transfusion units and postoperative incidence of G1 dysfunction in the Cry group suggests possibly more adverse effects of crystalloids in the perioperative period.

Dilution with three different solutions: plasmatic effects and quantity and quality of urinary output
T Langer1, E Carlesso1, A Prati1, M Monti1, L Zani1, G Lapichino1, B Comini1, D Andreis1, C Sparacino1, D Donossola1, L Gattinoni1
1Università degli Studi di Milano, Milan, Italy; 2Centro Ricerche Chirurgiche Precliniche, Università degli Studi, Milan, Italy

Introduction Crystalloids have different electrolyte composition and therefore different strong ion differences (SIDinf). The aim of the study was to investigate the response of the kidney to plasmatic acid-base changes induced by dilution with three crystalloid solutions at different SID.

Methods Six pigs (22 ± 4 kg) were anesthetized and mechanically ventilated. The respiratory rate was adjusted to maintain pCO2 constant. A urinary catheter was placed and connected to a urinary analyzer (Orivim, Paderno Dugnano, Italy) [1]. Pigs were randomly assigned to a sequence of dilutions (10% of body weight in 2 hours, followed by 4 hours of washout period) with the following three fluids: normal saline (NS), SID = 0, [Na] = 154, [Cl] = 154; lactated Ringer’s (LR), SID = 29, [Na] = 132, [Cl] = 112; and polysaline RII (Rill), SID = 55, [Na] = 140, [Cl] = 103. Blood gases and electrolytes as well as urinary pH (pHu), urinary electrolytes and urinary output (UO) were recorded at baseline and at the end of each dilution. Plasmatic SID was defined as [Na] + [K] + 2[Ca] – [Cl] – [Lac]. Variations (d) were defined as baseline – 2-hour value.

Results Plasmatic changes are consistent with previous in vitro studies [2]. dSID was mainly due to dCl]: 9.0 ± 1.7 for NS, no change for LR, −1.5 ± 1.6 for Rill. Of note, while no difference was yet observed for urinary electrolytes and UO, pHU significantly differed between the three solutions. See Table 1.

Efficacy and safety of 10% HES 130/0.4 versus 10% HES 200/0.5 for plasma volume expansion in cardiac surgery patients
C Ertmer1, H Van Aken1, H Wulf2, P Friederich3, C Mahf1, F Bepperling4, M Westphal4, W Gogarten1
1University Hospital, Münster, Germany; 2Phillips-University of Marburg, Germany; 3Fresenius Kabi, Bad Homburg, Germany

Introduction Hydroxyethyl starch (HES) solutions are commonly used for perioperative volume replacement. Whereas older HES specimens
tended to accumulate in the plasma and to cause negative effects on haemostasis, more recent products (for example, HES 130/0.4) are characterised by improved pharmacological properties. The present study was designed to compare the efficacy and safety of 10% HES 130/0.4 and 10% HES 200/0.5.

Methods In this post-hoc analysis of a prospective, randomised, double-blind, multicenter therapeutic equivalence trial, 76 patients undergoing elective on-pump cardiac surgery received perioperative volume replacement using either 10% HES 130/0.4 (n = 37) or 10% HES 200/0.5 (n = 39) up to a maximum dose of 20 ml/kg. Results Equivalent volumes of investigational medications were infused until 24 hours after the first administration (1,577 ± 1,540 ml; treatment difference 37 [-150; 223] ml; P < 0.0001 for equivalence). Whereas standard laboratory tests of coagulation were comparable between groups, von Willebrand factor activity on the first postoperative morning tended to be higher following treatment with 10% HES 130/0.4 as compared with 10% HES 200/0.5 (P = 0.025), with this difference being statistically significant in the per-protocol analysis (P = 0.025). Treatment groups were comparable concerning other safety parameters and the incidence of adverse drug reactions. In particular, renal function was well preserved in both groups.

Conclusions 10% HES 130/0.4 was equally effective and safe as compared with 10% HES 200/0.5 for volume therapy in patients undergoing cardiovascular surgery. Postoperative coagulation and renal function, as measured by standard laboratory tests, were similar among groups.

P88 Nicorandil versus nitroglycerin: a pilot study

V Singh1, S Momin2, B Shah3
1Addenbrooke’s NHS Foundation Trust, Cambridge, UK; 2West Suffolk Hospital NHS Trust, Bury St Edmunds, UK; 3NHIMS Medical College, Ahmedabad, India

Critical Care 2011, Volume 15 Suppl 1

Introduction Continuous exposure to nitrates is associated with tachyphylaxis. This study compares the effects and tolerance during intravenous treatment with nitroglycerin and nicorandil over a 48-hour period.

Methods Twenty patients with congestive heart failure and pulmonary capillary wedge pressure (PCWP) ≥18 mmHg were randomly assigned to nitroglycerin or nicorandil intravenous infusions. Doses were titrated to obtain a reduction of PCWP of at least 30% at 6 hours and then maintained for 48 hours.

Results There was no statistical difference between the groups in terms of age, sex, and NYHA grade. The pretreatment PCWP for nitroglycerin was 25.7 mmHg, decreasing to 18.4 mmHg at 6 hours. The values for nicorandil were 25.4 mmHg and 17.3 mmHg, respectively. There was no statistical difference between the two groups (P = 0.79 pretreatment and 0.23 at 6 hours). The mean PCWP values for 24 hours were 19.7 and 17.4, respectively, which was statistically significant (P = 0.036). Similarly, the values for 48 hours were 20.6 and 17.9, which was significant (P = 0.026) (see Table 1).

Conclusions Intravenous nicorandil administration gives similar reductions in PCWP compared with nitroglycerin with significantly less hemodynamic tolerance over a 48-hour period compared with nitroglycerin. This might represent a clinical advantage of nicorandil in the short-term treatment of patients with congestive heart failure.

P98 Dopamine versus norepinephrine in septic shock: a meta-analysis

S Sheny1, A Ganeshi2, A Rishi2, V Doshi3, S Lankala1, J Molin4, S Kogilwarvath5
1Rosalind Franklin University of Medicine and Science, North Chicago, IL, USA; 2Memorial University of Newfoundland, St John’s, Canada

Introduction The aim of this meta-analysis is to compare the changes in hemodynamic parameters among patients with septic shock who have received either of the two agents in their management and try to deduce the superiority of one over the other.

Methods A total of 880 articles were identified by a computerized search using MEDLINE, OVID and the Cochrane Central Register of Controlled Trials, of which six randomised controlled studies were included in the study. Observational data, retrospective studies or animal-based studies were excluded. Main outcome measures evaluated were the changes from the baseline in heart rate, mean arterial pressure, oxygen delivery index, oxygen extraction, systemic vascular resistance index (SVRI), cardiac index (CI), central venous pressure, blood lactate levels, urine output, mean pulmonary artery pressure (MPAP), pulmonary capillary wedge pressure, right ventricular ejection fraction (RVEF), arrhythmias and 28-day mortality rates. The statistical analysis was performed using Comprehensive Meta-Analysis software.

Results No significant difference was found in mortality between the two groups (RR = 1.067, CI = 0.984 to 1.157, P = 0.115). In the norepinephrine group, heart rate was significantly lower in comparison with baseline (mean change = –16.32 beats/minute, CI = –22.23 to –10.31, P < 0.001) and so also was the occurrence of arrhythmias (RR = 2.34, CI = 1.456 to 3.775, P < 0.001). The SVRI, however, was significantly higher in this group (difference in mean 185 dynes/cm5m2, CI = 141.214 to 229.05, P < 0.001). Patients who were on dopamine had significantly better RVEFs (mean difference = 2.38%, CI = 1.058 to 3.671, P < 0.001) and a lower lactate level (mean difference = –0.170 mmol/l, CI = –0.331 to –0.009, P = 0.038). Urine output, oxygen delivery, MPAP and oxygen consumption were not significantly different between the two groups.

Conclusions Patients who received dopamine had a better right ventricular ejection fraction, lower lactate levels, lower systemic vascular resistance index and a trend towards a better cardiac index. However, this group was noted to have more arrhythmias and a higher baseline heart rate versus the norepinephrine group. Overall, there was no difference in the 28-day mortality between the two groups. Although there are certain hemodynamic advantages, we were unable to deduce the superiority of one pressor. The results support the current practice of individualizing the choice of an initial vasopressor based on patient profile.

P90 Comparative evaluation of therapeutic interventions during hemorrhagic shock

D Fantoni1, DA Otsuki1, AR Martins1, JA Filho1, E Andrades1, E Chaib1, FA Vora1
1USP, São Paulo, Brazil; 2FCAV/UNESP, Jaboticabal, Brazil

Introduction Resuscitation of patients with hemorrhagic shock (HS) represents a challenge in emergency medicine. The uncontrollable bleeding and subsequent cardiovascular collapse are responsible for 40% of the early mortality rate in trauma.

Methods Twelve Large White pigs at 5 months of age, weighing 25 kg, were submitted to a surgical procedure for liver resection or autologous liver transplantation. Ketamine S+ (5 mg/kg, i.m.) and midazolam (0.5 mg/kg, i.m.) were used as a premedicant. Anesthesia was induced with propofol (3 mg/kg, i.v.) and maintained with 1.5% isoflurano
end-tidal concentration and volume-controlled ventilation (8 ml/kg) on 40% inspired oxygen fraction. Analgesia and neuromuscular blockade were accomplishments with continuous infusion of fentanyl (0.4 mg/kg/minute) and pancuronium (0.3 mg/kg/hour). The shock was diagnosed when blood loss exceeds 40% of the total blood volume. The HS results in mean arterial pressure reduce (MAP ≤50 mmHg), 50% cardiac output reduction (CO) and central venous saturation (SvO₂) decreased to 70 mmHg. The animals underwent hemodynamic, arterial blood gases and venous monitoring, at baseline (t0), impact moment (t1), after treatment (t2), intervals of 15 minutes after shock treatment (t3, t4, t5, t6), and 120 minutes after treatment (t7). Subsequent to shock diagnosis, the animals were randomly divided into GI treated with vasopressin (0.01 IU/kg/minute), norepinephrine (0.3 mg/kg/minute) and Ringer’s lactate solution (aliquots of 20 ml/kg/20 minutes until MAP >60 mmHg), GI was equal to GI but ringer lactate administration was replaced during 20 minutes of whole blood stored during 10 days at half blood loss volume.

Results See Table 1. Both groups showed a significant parameter decrease during hemorrhagic shock (t1) compared with t0. After treatment GI showed improvements in all parameters, GI showed improvement until t3. During t4 the animals presented a significant increase in K levels, lactate and decreased SvO₂, CO, MAP followed by an increase in SvO₂ (89%). The differences between the two groups and moments were statistically significant (P >0.01). GI had a 50% of mortality rate between t4 and t5 related with potassium increase. Subsequent to animal blood treatment, the patients showed an improvement in T wave, ventricular fibrillation and death.

Conclusions It is possible to conclude that whole blood replacement in animals with HS should be slow and steady to avoid the effects of high K administration during a short period. Those therapeutic interventions are indicated to avoid the consequences of HS.

P92 Vasopressin for the treatment of vasodilatory shock: an ESICM systematic review and a meta-analysis
A Polito, E Parisini, Z Ricci, S Picardo, D Anne
1Ospedale Pediatrico Bambino Gesù, Roma, Italy; 2Italian Institute of Technology, Milan, Italy; 3Hôpital Raymond Poincaré (Assistance Publique-Hôpitaux de Paris), Garches, France

Introduction We examine benefits and risks of vasopressin/terlipressin use in patients with vasodilatory shock on mortality and morbidity.

Methods We searched the CENTRAL, MEDLINE, Embase, and LILACS (through to August 2010) databases. Randomized and quasi-randomized trials of vasopressin/terlipressin versus placebo or supportive treatment in adult and pediatric patients with vasodilatory shock were included. The primary outcome for this review was short-term all-cause mortality.

Results We computed data from 10 randomized trials (n = 1,111). The overall (28-day, 30-day, ICU, hospital and 24-hour) mortality for those treated with vasopressin and terlipressin versus control patients was 237 of 582 (40.7%) versus 226 of 528 (42.8%) (RR, 0.92; 95% CI, 0.81 to 1.01).

Conclusions The results of the present study suggest that vasopressinergic V1 agonists allow a reduction in catecholamine requirements with no negative impact on microvascular perfusion as compared with sole NE therapy.
P93
Effects of early versus delayed terlipressin infusion on hemodynamics and catecholamine requirements in ovine septic shock

TG Kampmeier1, M Westphal1, S Rehberg1, A Morelli2, M Lange1, H Van Aken1, C Ertmer1
1University Hospital of Münster, Germany; 2University of Rome ‘La Sapienza’, Rome, Italy

Introduction Terlipressin (TP) is increasingly used in catecholamine-dependent septic shock. Whereas recent data suggest advantages of continuous infusion over repetitive bolus infusion, the optimal time of TP initiation remains unclear. The present study was designed as a prospective laboratory experiment to compare the impact of early versus delayed TP infusion on key hemodynamic variables, as well as fluid and catecholamine requirements in ovine septic shock.

Methods Twenty-three healthy female sheep were anesthetized and instrumented for hemodynamic monitoring. A median laparotomy was performed and 1.5 g/kg feces were taken from a cecal incision. After gut suture and insertion of peritoneal drains, the abdomen was closed. Following baseline measurements, autologous feces were injected into the abdominal cavity via a drain. When septic shock had established (MAP <60 mmHg and arterial lactate >1.8 mmol/l), causal therapy (meropenem infusion and peritoneal lavage every 8 hours) and supportive treatment (volume therapy guided by stroke volume) were increased to maintain MAP >60 mmHg and arterial lactate <1.8 mmol/l. Terlipressin (2 μg/kg/hour) started when NE requirements exceeded 0.3 μg/kg/minute (delayed TP; n = 8), or to continuous TP infusion (2 μg/kg/hour) started when NE requirements exceeded 0.3 μg/kg/minute (delayed TP; n = 8). After 24 hours of therapy, the surviving sheep were killed in deep anesthesia. A second inotropic drug infusion was added when AHF persisted with average CI of 2.1 ± 0.15 l/minute/m² and left ventricular ejection fraction of 0.40 ± 0.09. See Figure 2.

Conclusions No significant effect of vasopressin/terlipressin therapy on all-cause mortality was demonstrated. Overall, there is no evidence to support the routine use of vasopressin or terlipressin in the management of patients with vasodilatory shock. There was, however, a reduction in the dose of norepinephrine used for those patients receiving vasopressin/terlipressin.

P95
Treatment of calcium channel blocker overdose with levosimendan

A Sencan, T Adanır, G Terzi, A Atay, N Karahan
Izmir Ataturk Educational and Research Hospital, Izmir, Turkey

Introduction We report a case in which cardiovascular collapse after suicidal calcium channel blocker (CCB) overdose was successfully treated with levosimendan with traditional treatment.

Methods A 20-year-old male who had taken 250 mg amlodipin besilate was admitted to the ICU from the Emergency Department. His blood pressure was 70/52 mmHg, heart rate 95 bpm and oxygen saturation was 99%. An arterial catheter was inserted and arterial blood pressure (ABP) of 52/20 mmHg was measured. He was tracheally intubated and dopamine infusion of 10 μg/kg/minute, dobutamine infusion of 5 μg/kg/minute was initiated. Dopamine and dobutamine infusions were increased to 20 μg/kg/minute and 15 μg/kg/minute, respectively. Despite very high doses of vasopressors, his ABP tended to decrease below 50 mmHg and frequent epinephrine boluses were given. Upon arrival 8 hours later, levosimendan was initiated without an initial loading dose infusion of 0.2 μg/kg/minute. In 4 hours from initiation of levosimendan treatment, dopamine and dopamine infusions were stopped respectively. After full recovery the patient was discharged 72 hours after arrival.

Results CCB overdose causes intractable hypotension, bradycardia, cardiac conduction abnormalities and depression of myocardial contractility, leading to central nervous system, respiratory and metabolic disorders that are often refractory to standard resuscitation methods. Therapy of intoxication includes measures to inhibit further ingestion and absorption with gastric lavage and activated charcoal, to maintain adequate blood pressure with high doses of catecholamine and fluid replacement and to reverse negative inotropic effects by β-adrenergic agonists, phosphodiesterase inhibitors, glucagon, insulin with dextrose and calcium salt. Well-known inotropic agents show their effects via increasing intracellular calcium level. In CCB overdose patients, the efficiency of these drugs was limited because...
the calcium channels have already been blocked. A new inotropic drug, levosimendan, acts as a calcium sensitizer and increases the association rate of myosin actin cross-bridges and slows down their dissociation rate by binding to troponin C. It also exhibits systemic and coronary vasodilatation via ATP-sensitive potassium channels in vascular smooth muscle cells and on mitochondria.

Conclusions We suggest that levosimendan can be considered an additional treatment option in patients with cardiovascular collapse due to CCB intoxication that is refractory to standard management.

P96
Effect of different antioxidants in ischemia–reperfusion syndrome
W Hoyos, L Alfaro, B Garcia-Prieto, G Lopez, P Flores
Universidad, Santa Tecla, La Libertad, El Salvador

Introduction The ischemia–reperfusion syndrome commonly seen in different clinical scenarios leads to acute renal failure and it is known that the free oxygen radicals play an important role in the pathophysiology of this injury. Recent studies suggest that the use of antioxidants can provide renal protection, reducing parenchymal lesions and expression of inflammatory mediators, improving renal function, resulting in a better outcome.

Methods We studied the effect of DMSO, DMSO–ascorbic acid and DMSO–N-acetylcysteine administration on renal injury induced by I/R. Thirty minutes renal ischemia was induced in 50 male, New Zealand rabbits. The subjects were divided into five groups: (A) Sham, unilateral nephrectomy, no ischemia induced. (B) Control group. (C) DMSO, unilateral nephrectomy, I/R treated with DMSO 3.8 mg/kg. (D) DMSO–ascorbic acid, unilateral nephrectomy, I/R treated with ascorbic acid 150 mg/kg and DMSO 3.8 mg/kg. (E) DMSO–N-acetylcysteine unilateral nephrectomy, I/R treated with N-acetylcysteine 20 mg/kg and DMSO 3.8 mg/kg. All subjects were given 8 hours of reperfusion. Two blood samples were taken at baseline and after the reperfusion phase. Each sample was tested for serum creatinine. After reperfusion left nephrectomy was performed on each subject before euthanasia. A pathological analysis evaluated tubular and basement membrane changes. The level of injury was scaled in three stages: mild, moderate and severe.

Results The histological analysis showed a total damage in 59% of the control group, compared with DMSO 33%, DMSO–AA 51%, and DMSO–NAC 44% (Figure 1). Also, inflammatory properties were absent or to a lesser extent in those groups who used antioxidants. Serum creatinine analysis in the control group showed higher values compared with the association of DMSO–AA, DMSO–NAC where the increases were lower (Figure 2).

Conclusions The findings imply that reactive oxygen species play a causal role in I/R-induced renal injury, and that antioxidants exert renoprotective effects, probably by radical scavenging and antioxidant activities, in this way diminishing renal function deterioration.

Searching for mechanisms that matter in septic acute kidney injury: an experimental study
J Benes1, J Chvojka1, R Sykora2, J Radej1, A Krouzecky1, J Novak1, M Matejovic1
1Charles University Teaching Hospital, Plzen, Czech Republic; 2District Hospital, Karlovy Vary, Czech Republic

Introduction Both hemodynamic and nonhemodynamic factors are implicated in the pathogenesis of sepsis-induced acute kidney injury (SAKI). However, despite similar septic insult, not all patients develop SAKI. The reasons for the difference in sensitivity to AKI are unknown. Therefore, we sought to analyze dynamic changes in renal hemodynamic and non-hemodynamic responses to sepsis in animals who developed AKI and those who did not.

Methods Thirty-six pigs were anesthetized, mechanically ventilated and instrumented. After a recovery period, progressive sepsis was induced either by peritonitis (n = 13) or by i.v. infusion of Pseudomonas aeruginosa (n = 15). Eight sham-operated animals served as time-matched controls. All animals received standard ICU care including goal-directed hemodynamic management. Before and at 12, 18 and 24 hours of sepsis systemic and renal hemodynamic, microcirculatory and inflammatory variables were measured. AKI development was defined using AKIN criteria.

Results Fourteen pigs (50%) developed AKI (62% in peritonitis model, 40% in bacteria infusion model) with a significant increase in serum creatinine observed already at 18 hours of sepsis. There were no differences in the systemic hemodynamics and vasopressor support between AKI and non-AKI groups. Although time-dependent reduction in cortical microvascular perfusion was comparable in both groups, only AKI animals developed a progressive increase in renal vascular resistance. This intrarenal vasoconstriction was preceded by a marked overproduction of serum cytokines (TNFa, IL-6) and markers of oxidative stress (TBARS), observed already at 12 hours of sepsis. This induction of proinflammatory response was delayed in non-AKI animals.

Conclusions The observed variability in susceptibility to SAKI in our models replicates that of human disease. This heterogeneity allowed us to isolate and study factors discriminating AKI from non-AKI. Early systemic inflammation coupled with late intrarenal vasoconstriction appears to be major determinant of the initiation of SAKI. Genetic and proteomic analyses underlying the observed differences are being analyzed.

Raised serum creatinine at admission to critical care is independently associated with mortality in patients with decompensated alcoholic liver disease
A Whiteside1, P Whiting1
1Sheffield Teaching Hospitals NHS Trust, York, UK; 2Northern General Hospital, Sheffield, UK

Introduction Patients with decompensated alcoholic liver disease have a high mortality if they require critical care. Previous studies have indicated that patients who required renal replacement therapy have high mortality, but there is little research on the mortality rate of those with renal impairment not requiring support.

Methods A retrospective cohort study of patients with a diagnosis of decompensated alcoholic liver disease admitted to the critical care department of two hospitals over a 3-year period was conducted (n = 51).

Results There was no significant difference in the ages (50.8 and 50.3, P = 0.9) or sexes of those who survived and those who died during hospital stay. Hospital, 6-month and 1-year mortality rates were 45%, 49% and 51%, respectively. There was no significant difference in the number of patients requiring advanced respiratory support (60% vs. 74%, P = 0.76). Ninety-four per cent of patients who had a serum creatinine of 150 mmol/l or greater at admission to critical care died during their hospital stay.

Conclusions The futility of admitting patients with decompensated alcoholic liver disease with serum creatinine of 150 mmol/l or greater should be considered at the time of referral to critical care, as they have a 94% mortality.

Contrast-induced nephropathy in ITU patients: outcomes of a university hospital re-audit
K Lam, T Chan, R Lovelby, J Walker
Royal Liverpool University Hospital, Liverpool, UK

Introduction Contrast-induced nephropathy (CIN) is a significant and preventable cause of renal failure associated with increased mortality, hospital stay and long-term haemodialysis. Critically ill patients have increased risks of developing CIN due to pre-existing disease and sepsis. A university hospital audit in 2007 found that 22.2% of ITU patients had significant rises in creatinine following intravenous contrast medium (IVCM). In 2008, IVCM guidelines were implemented trust-wide to detect patients with pre-existing renal impairment and provide guidance for pre-optimisation and prophylactic measures.

Methods A retrospective cohort study of ITU patients since the introduction of the IVCM guidelines. In 2008, IVCM guidelines were implemented trust-wide to detect patients with pre-existing renal impairment and provide guidance for pre-optimisation and prophylactic measures. In 2008, IVCM guidelines were implemented trust-wide to detect patients with pre-existing renal impairment and provide guidance for pre-optimisation and prophylactic measures depending on CKD stage, including early renal team involvement.

Results The incidence of CIN has decreased to 17.5% in medical and surgical ITU patients since the introduction of the IVCM guidelines.

Evaluation of acute kidney injury with pediatric-modified RIFLE criteria after pediatric cardiac surgery
P Zeyneloglu, A Pirat, E Baskin, C Araz, M Ozkan, N Bayraktar, G Arslan
Baskent University Hospital, Ankara, Turkey

Introduction Acute kidney injury (AKI) is a serious complication associated with increased morbidity and mortality in pediatric patients undergoing surgery for congenital heart disease. The aim of this study was to evaluate children with AKI after pediatric cardiac surgery using pediatric-modified RIFLE (prRIFLE) criteria and to investigate the value of serum cystatin C in patients with AKI.

Methods Eighty-one children undergoing cardiopulmonary bypass (CPB) for surgical correction of acyanotic congenital heart disease were prospectively enrolled in the study. Serial blood samples were collected to measure serum cystatin C and creatinine levels. The primary outcome measure was AKI, defined as ≥50% increase in serum creatinine from baseline.

Results Twenty-one children (26%) developed AKI, in which risk occurred in 12 (15%), injury in three (4%) and failure in six (7%) of the patients diagnosed with serum creatinine. Patients with AKI were significantly younger than patients without AKI (P = 0.002). No differences were noted with respect to CPB and aortic cross-clamp durations in those with and without AKI (P >0.05). Postoperative 24-hour inotrope scores were significantly higher in children who developed AKI (P = 0.003). Serum cystatin C concentrations were significantly increased in AKI patients at 2 hours after CPB (P = 0.029) and remained elevated at 24 hours (P <0.001) and 48 hours (P = 0.001). There was a significant positive correlation between presence of AKI and serum cystatin C levels (P <0.05). A significant negative correlation was found between age and AKI (r = -0.344, P = 0.002).

Conclusions AKI develops in 26% of patients after pediatric cardiac surgery. Our results suggest that patients with AKI were younger and had postoperative higher serum cystatin C levels and higher inotrope scores when compared with patients without AKI.

Acute kidney injury after coronary artery bypass grafting surgery
P Zeyneloglu, A Pirat, N Vezipoglu, A Sezgin, G Arslan
Baskent University Hospital, Ankara, Turkey

Introduction Acute kidney injury (AKI) after coronary artery bypass grafting (CABG) surgery is associated with increased postoperative morbidity and mortality. The aim of this study was to apply the RIFLE (risk (R), injury (I), failure (F), loss (L) and end-stage kidney disease (E)) criteria in patients after CABG surgery, to identify intraoperative risk factors for occurrence of AKI and to analyze the impact of AKI on mortality.

Methods Five hundred consecutive patients who underwent CABG surgery between December 2004 and December 2007 were retrospectively studied. Those who had combined valve and coronary surgery, off-pump surgery and those receiving renal replacement therapy preoperatively were excluded from the study. The primary outcome measure was AKI, defined as ≥50% increase in serum creatinine from baseline.

Results The mean age of the patients (74% male) was 60.9 ± 9.8 years. The incidence of AKI was 4%, in which risk occurred in 2%, injury in 1% and failure in 1% of the patients. The cardiopulmonary bypass (CPB) time and duration of the surgery was significantly longer in patients who developed AKI (P = 0.024, P = 0.002). The amounts of fluid and blood administered and vasopressor requirements during surgeries were similar between patients who developed AKI and those without AKI (P >0.05). The need for intraoperative cardiopulmonary resuscitation (CPR), the use of intra-aortic balloon pump (IABP) and total circulatory arrest (TCA) was significantly higher in AKI patients (P = 0.002, P = 0.001 and P = 0.036, respectively). When compared with non-AKI patients, postoperative mortality for patients experiencing AKI was significantly
high ($P = 0.001$). There was a significant positive correlation between presence of postoperative mortality and AKI ($r = 0.232$, $P < 0.001$).

**Conclusions** The results suggest that AKI develops in 4% of patients after CABG surgery. Intraoperative risk factors for occurrence of AKI include longer duration of surgery, CPB time and requirements of CPR, IABP and TCA usage. In addition, postoperative development of AKI is associated with mortality.

**Increased severity of acute kidney injury does not increase long-term mortality**

MB Pereira¹, DMT Zanetta², RCRM Abdulkader³
¹University of São Paulo, Brazil; ²School of Medicine, São Paulo, Brazil

**Introduction** Acute kidney injury (AKI) increases either in-hospital mortality or long-term mortality. The severity of AKI has been associated with early mortality; however, studies on its role in long-term mortality have shown contradictory results.

**Methods** We studied 300 critically ill patients who had survived an AKI episode defined by AKIN creatinine criteria. All patients were attended by nephrologists in 2005 to 2006 and studied in May 2008. Exclusion criteria: age $<18$ years, presumed etiology other than acute tubular necrosis, baseline creatinine $>3.5$ mg/dl, nephrology follow-up $<2$ days and renal transplant. Analyzed variables: age; gender; type of admission; AKI etiology (ischemia, nephrotoxicity, sepsis or multifactorial); baseline and hospital discharge GFR (evaluated by MDRD equation); AKIN classification (1, 2, 3); need for dialysis, mechanical ventilation or vasoactive drugs; presence of comorbidities (hypertension, diabetes, heart failure, cancer or chronic liver disease); and functional recovery at hospital discharge (discharge GFR $<1.1$ baseline GFR). Survivors and nonsurvivors were compared by t test, Mann–Whitney test, Fischer’s test or chi-square test, as appropriate. Causes of death were identified by death certificate. Data are presented as median (25 to 75 IQ) or percentage.

**Results** At the end of the study 105 patients had died (35%). Death occurred 194 days (69 to 444) after hospital discharge. The main cause of death was cardiovascular diseases (39%). The comparison between survivors and nonsurvivors showed that survivors had higher percentage of males (67 and 52%, $P = 0.01$), were younger (63 (49 to 72) and 70 years (56 to 79), $P < 0.0001$), had more multifactorial AKI etiology (26 and 41%, $P = 0.01$) and less heart failure as comorbidity (17 and 32%, $P = 0.006$). Unexpectedly, more survivors had needed mechanical ventilation (57 and 32%, $P = 0.006$) but neither vasoactive drugs (60 and 61%, $P > 0.05$) nor dialysis (38 and 39%, $P > 0.05$). See Table 1.

**Conclusions** Long-term survival after AKI is not associated with the AKI severity but with baseline renal function.

### P103

**Any level of acute kidney injury may be associated with mortality in critically ill patients**

AP Rucks, AF Menegalli, DA Becker, JM Andrade, G Friedman
Complexo Hospitalar Santa Casa, Porto Alegre, Brazil

**Introduction** Acute kidney injury (AKI) is a common condition in critically ill patients [1]. It is an independent risk factor for in-hospital mortality in this population [2]. The goal of this research is to classify critically ill patients within RIFLE criteria [3] and assess its impact on 30-day in-hospital mortality.

**Methods** From September 2009 to July 2010, all patients admitted to the two ICUs of Santa Casa Hospital were included in this study. Age, gender, SOFA and APACHE scores, origin, serum creatinine, whether they were clinical or surgical, and outcome were noted. Then patients were classified as ‘no AKI’, ‘risk’, ‘injury’, or ‘failure’ according to RIFLE criteria. The 30-day in-hospital mortality was also evaluated. A multivariate analysis model was created from potentially confusing variables that were statistically significant in an unvaried analysis. $P < 0.05$ was considered statistically significant.

**Results** Two hundred and six patients were included. Most of them were women (54%), with an average age of 62 years. The mean APACHE score was 17 and the mean SOFA score was 5.8. The proportion, according to the RIFLE criteria, for patients at ‘risk’ was 17%, at ‘injury’ was 14%, ‘failure’ was 26% and ‘no AKI’ was 42%. The relative risk for 30-day in-hospital mortality for the group ‘no AKI’ was 0.5 (95% CI = 0.39 to 0.63; $P < 0.001$); for the ‘risk’ group was 1.7 (95% CI = 1.03 to 3.06; $P = 0.037$); for the ‘injury’ group was 1.66 (95% CI = 0.97 to 2.85; $P = 0.062$); and for the ‘failure’ group was 2.03 (95% CI = 1.22 to 3.37; $P = 0.006$).

**Conclusions** AKI incidence, according to RIFLE classification, is high in critically ill patients. There is an association between AKI severity and mortality. It is noticeable that patients in the ‘risk’ group have increased mortality.

**A comparison of four methods to define timing of acute kidney injury**

KA Wlodzimirow, A Abu-Hanna, C Bouman
Academic Medical Center, Amsterdam, the Netherlands

**Introduction** RIFLE provides standardized criteria for defining acute kidney injury (AKI) [1]. It is based on changes in serum creatinine (sCr), in relation to a premorbid sCr, and on urine output. When premorbid sCr is unknown, baseline sCr is estimated. Often only sCr is used (RIFLEcreat). Thus there are four methods for defining AKI: actual RIFLE, calculated RIFLEcreat, estimated RIFLE and estimated RIFLEcreat. There is much interest for biomarkers predicting early AKI [2]. Critical for determining a biomarker’s performance of AKI is the diagnosis of the first day of AKI (AKI-0). We compared the impact of four AKI definitions on determining AKI-0.

**Methods** An observational study for 6 months in ICU patients admitted ≥48 hours. For the first 7 days we calculated daily the number of AKI patients. The results suggest that AKI develops in 4% of patients with early mortality; however, studies on its role in long-term mortality have shown contradictory results.

**Results** The early diagnosis of AKI is significantly reduced when urine output criteria are neglected in the RIFLE definition, and also when baseline sCr is estimated. This may significantly impact the assessment of biomarker performance.

**Validation of the AKIN criteria definition using high-resolution ICU data from the MIMIC-II database**

T Mandelbaum, DJ Scott, J Lee, MD Howell, A Malhotra

1Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA; 2MIT-HST, Cambridge, MA, USA; 3Brigham and Women's Hospital

**Introduction** Recently the Acute Kidney Injury (AKI) Network proposed criteria for the definition of AKI in the critically ill. The minimum hourly urine output rate used to define oliguria (<0.5 ml/kg/hour) is based exclusively on clinical experience and animal models, not on clinical investigation. Moreover, the minimum duration of oliguria (6 hours) is based on clinical experience and was never experimentally determined. We used a massive database of ICU patients (MIMIC) to continuously vary the observation period and threshold of urine output measurements to determine optimal AKI definitions for improved in-hospital mortality prediction.

**Methods** After excluding end-stage renal disease, 14,536 adult patients were included. Various AKI thresholds corresponding to different observation periods and urine output measurement thresholds were analyzed using a multivariate logistic regression model for each choice of thresholds. A total of 470 regression models were plotted. We controlled for sex, age, SOFA and co-morbidities (ICD-9 codes).

To visualize dependence of adjusted mortality rate and mortality predictive power on AKI definition, we generated 3D and contour plots.

**Results** The UO versus mortality plot demonstrates that when UO <0.5 the mortality rate increases rapidly as urine output decreases. Mortality increases sharply for observation periods up to 5 hours and then the rate of increase is reduced until a plateau is reached at approximately 24 hours. Cross-sections at 6, 12 and 24 hours of the UO mortality plot shows that the mortality rate of AKI 1 and AKI 2 are similar but differ significantly from AKI 3. See Figure 1.

**Conclusions** The current AKIN recommendation that uses a urine output of 0.5 ml/kg/hour is valid. Since AKIN’s stages 1 and 2 were found to exhibit similar mortality rates, we propose a reduction in the AKI 2 threshold to 0.4 ml/kg/hour to better delineate among the three stages. We demonstrated that the mortality rate increases sharply during the first 5 hours of oliguria. Hence, the current used observation period (6 hours) seems to be valid.

---

**Figure 1 (abstract P104).** Distribution of AKI-0.

---

**Figure 1 (abstract P105).** (a) Urine output mortality plot. (b) Cross-section at 6, 12, 24 hours.
Conclusions Higher sCr levels correspond with higher urinary excretion of all biomarkers, especially after GM use. In addition, the urinary biomarker GSTP1-1 might be useful for early detection of AKI in the neonatal ICU.

P107

Neutrophil gelatinase-associated lipocalin in ICU patients developing oliguria

A Romanò1, M Mijl1, V Piersel1, T El Mahi1, C Hanciq, E Stevens2.

CHU Saint-Pierre, Brussels, Belgium

Introduction Plasma neutrophil gelatinase-associated lipocalin (pNGAL) is an early biomarker of acute kidney injury (AKI) [1].

Methods A prospective observational study enrolling adult ICU patients developing a first episode of oliguria defined as urinary output lower than 0.5 ml/kg/hour for at least only 2 consecutive hours despite conventional treatment and appropriate fluid resuscitation. pNGAL ( Biosite, Inverness, San Diego, CA, USA), plasma cystatin C, plasma and urinary sodium and creatinine, were measured to determine on 1 hour the fraction of excretion of the filtered sodium (FeNa) and the glomerular filtration rate (GFR). The SOFA score and RI score (2) were calculated. Hospital mortality was recorded.

Results Ninety-three patients were enrolled: 52 presented with 0, 15 with R, 13 with I and 10 with F RIFLE score. The median SOFA score was 3 (minimum: 0 to maximum: 17). Sepsis was the main diagnostic in 38 patients, 27 were cardiac surgery patients who underwent cardiopulmonary bypass (CBP) and 28 were miscellaneous other category patients (hemorrhagic shock, hypotensive surgery, trauma with crush, and so on). In-hospital mortality of the studied cohort was 20%. Eighty-five percent of FeNa were less than 1%, suggesting active antidiuresis and sodium reabsorption. The distribution of pNGAL between survivors (median 61 ng/ml; 95% CI = 59 to 91 ng/ml) and nonsurvivors (median 182 ng/ml; 95% CI = 86 to 594 ng/ml) was statistically significant (P = 0.006, Wilcoxon rank test). Distribution of pNGAL in patients post CPB (median 59 ng/ml; 95% CI = 59 to 59), was statistically different from patients with sepsis (median 180 ng/ml; 95% CI = 92 to 276) and the last group (median 85 ng/ml; 95% CI = 59 to 166) with respectively P <0.0001 and 0.024 after Bonferroni’s correction.

No correlation between pNGAL and FeNa was found (Spearman’s rho = 0.309; 95% CI = 0.11 to 0.48), nor between pNGAL and 1-hour GFR (Spearman’s rho = –0.55; 95% CI = –0.68 to –0.38), nor between pNGAL and plasma cystatin C (Spearman’s rho = 0.62; 95% CI = 0.47 to 0.73).

Conclusions pNGAL rises in early oliguria independently while kidney function markers such as GFR, FeNa and cystatin C may have remained unaffected at this stage. Sepsis is a stronger trigger for pNGAL elevation.

Use of Doppler ultrasound renal resistive index and neutrophil gelatinase-associated lipocalin in prediction of acute kidney injury in patients with septic shock

 CW Ngai1, MF Lam1, SH Loa, CW Cheung1, WM Chan1.

‘Adult Intensive Care Unit, ‘Department of Medicine, and ‘Department of Surgery, Queen Mary Hospital, Pokfulam, Hong Kong, ‘Department of Anaesthesiology, The University of Hong Kong, Pokfulam, Hong Kong

Introduction Acute kidney injury (AKI) is common in septic shock and there is no good marker to predict it. Neutrophil gelatinase-associated lipocalin (NGAL) is a novel renal biomarker showing promising results in prediction of AKI in patients across different clinical settings. Another potential marker is the resistive index (RI) of renal interlobar artery (calculated as (peak systolic velocity – end diastolic velocity) / peak systolic velocity), which has been shown to be useful in identifying those who will develop AKI in patients with septic shock. The aim of this study is to evaluate the usefulness of RI and NGAL in the early detection of AKI.

Methods A prospective, observational study in a 20-bed medical/surgical ICU of a university teaching hospital. All patients with septic shock were recruited, excluding those with chronic renal failure (serum creatinine >120 μmol/l). Within the first 24 hours after the introduction of vasoressor, urine and serum were collected for NGAL measurement and RI was determined by two independent operators. The occurrence of AKI was measured at day 3, according to RIFLE criteria. RI and NGAL were compared between patients with (RIFLE-F) and without (RIFLE-0/R) AKI.

Results During the period from August to November 2010, 20 patients (age 58 ± 16) with septic shock were recruited. Eleven patients were classified as having AKI. No significant difference in baseline characteristics such as APACHE II score and baseline creatinine was shown at enrollment. RI, serum-NGAL and urine-NGAL were all higher in patients with AKI (RI: 0.749 ± 0.0679 (mean ± SD) vs. 0.585 ± 0.0983, P <0.001; serum-NGAL: 2,182 ± 838 ng/ml (mean ± SD) vs. 1,075 ± 1,006, P = 0.015; urine-NGAL: 2,099 ± 3,370 vs. 993 ± 1,789 (median ± IQR), P = 0.025). Area under the ROC curve for RI and serum-NGAL was the 0.909 (±0.088, P = 0.002) and 0.808 (±0.113, P = 0.02), respectively. For RI, using 0.65 as the cut-off, sensitivity and specificity was 1 and 0.89, respectively. For serum-NGAL, using a cut-off of 1,200 ng/ml, it had a sensitivity of 1 and specificity of 0.67. Inter-observer difference of RI was low (0.0015 ± 0.0074 (mean ± SD)).

Conclusions Doppler ultrasound renal RI is non-invasive, rapidly available and easily reproducible, and is at least as good as NGAL as a predictor of AKI in patients with septic shock.

Removal of drug delivered via a central venous catheter by a dual-lumen haemodiafiltration catheter inserted at the same site: a quantitative flow model

R Kam1, JM Mari2, TJ Wigmore3.

1 Imperial College London, UK; 2 INSERM, Lyon, France; 3 Royal Marsden Hospital, London, UK

Introduction The objectives of this study were to model and visualise flow in a central vein during continuous venovenous haemodiafiltration (HDF), to measure drug removal when an HDF catheter is co-located with a central venous catheter (CVC) infusion medication. Dual lumen HDF catheters are commonly used to deliver continuous venovenous renal replacement therapy in critical care. These catheters are often co-located with a CVC used to infuse drugs, with the tips lying in close approximation in a great vein. The effect of this co-location on drug delivery to the patient due to aspiration by the HDF machine may be of serious import, with the elimination of important vasoactive drugs or minimally protein-bound antibiotics just two possibilities. This effect has never been studied.

Methods A model of a human central vein was constructed using transparent polyvinyl chloride piping. A CVC and an HDF catheter were inserted into this and water flow in the central vein and extracorporeal circuit was generated by centrifugal pumps at physiological volume flow rates. Ink was used as a visual tracer and creatinine solution as a quantifiable tracer to determine the extent of removal of CVC infusate via the HDF catheter. The longitudinal distance of the CVC infusion point from the arterial port of the HDF catheter was altered to quantify its effect on tracer removal.

Results Volume flow rates of 1.45 l/minute and 200 ml/minute were achieved in the central vein model and the HDF circuit model, respectively, with laminar flow in the central vein confirmed by Duplex imaging and ink flow analysis. All visible ink and 100% of creatinine tracer infused via the CVC were aspirated by the HDF catheter unless the point of infusion was ≥ 1 cm downstream of the proximal aspect of the arterial port. No measurable tracer was aspirated when the infusion was ≥2 cm downstream. Orientation of side ports did not significantly affect tracer removal.

Conclusions This initial study suggests that drugs infused via a CVC co-located with an in-use HDF catheter may be completely and immediately
aspirated into the extracorporeal circuit. This phenomenon could lead to significant drug underdosing with potentially severely deleterious consequences for patients. When co-location cannot be avoided, drugs with important immediate effects or high membrane clearance should be infused sufficiently distal to the inlet of an adjacent HDF catheter.

Methods

Consecutive patients on chronic intermittent hemodialysis for ESKD were eligible for our study. SV and heart rate were measured continuously and non-invasively using NICOM, a technique based on chest bioelectrical impedance. Blood pressure was measured intermittently with a sphygmomanometer. Peripheral and microcirculatory perfusion were measured intermittently with sidestream dark-field (SDF) imaging (sublingual area), and continuously with forearm-to-finger temperature gradient (△Tskin-diff) and photoplethysmography (PPG) (finger). All parameters were assessed before (baseline) and after 4 hours at the end of UF.

Results

Data are presented as median (IQR). Twenty-one patients (13 males, median age 59 (51 to 66) years) were included in our study. A median volume of 2,200 (1,850 to 2,850) ml was removed. SV and mean arterial pressure decreased during UF from 75 (58 to 84) ml to 51 (37 to 67) ml (P <0.01) and from 102 (88 to 109) mmHg to 85 (75 to 95) mmHg (P <0.001), respectively, while heart rate did not change. At baseline all parameters of peripheral and microcirculatory perfusion were undisturbed. During UF, Tskин-diff and the PPG of the finger did not change. Sublingual microvascular flow index and vessel density measured with SDF slightly decreased from 3.0 (3.0 to 3.0) to 2.8 (2.7 to 2.9) (P <0.001) and from 10.6 (9.9 to 11.1) n/mm to 9.9 (9.2 to 10.5) n/mm (P <0.05), respectively.

Conclusions

UF leads to a significant and uniform decrease in volume status in patients with ESKD but surprisingly this was not associated with large decreases in peripheral and microcirculatory perfusion. Therefore caution is warranted when interpreting systemic hemodynamic parameters in terms of hypovolemia and hypoperfusion when peripheral perfusion is not evidently impaired.

P110 Effect of total parenteral nutrition on the duration of haemofilter circuit

S Saha, P Shah, J Gibbs, J Collins

Broomfield Hospital, Chelmsford, UK

Introduction

An effective haemofilter circuit is essential for performing continuous renal replacement therapy (CRRT) efficiently and without interruption. Premature clotting is a major problem in the daily practice of CRRT associated with blood loss [1], increased workload and cost implications. Early clotting is related to various factors ranging from bio-incompatibility of the CRRT circuit material, the modality used, ineffective anticoagulation, to site of catheter placement. Shortened haemofilter circuit survival time due to high lipid content in total parenteral nutrition (TPN) has also been described in a case report [2]. We wish to determine whether TPN infusion led to shortening of haemofilter circuit duration.

Methods

We conducted a retrospective analysis of notes of patients who had undergone CRRT in an adult general ICU over 2 years. Demographic (age, sex) and clinical (platelet count, INR, APTT, anticoagulant used and duration of infusion of anticoagulant); data that are known to influence the duration of CRRT circuit were compared. Cycles terminated because of high Pin pressure or documented failure of the circuit were included in the study and the duration of the circuit was determined. Note was made if the patient was on TPN during CRRT. They were divided in two groups: CRRT with TPN, and CRRT without TPN. All patients had the similar make vasvacth (14Fr, polyurethane catheter; Logitech) and the same CRRT machine and circuit.

Results

One hundred and twenty-one patients had undergone CRRT in the unit in the past 2 years. In total, 246 CRRT circuits were used. A linear regression model was fitted to the duration of filtration with TPN as a categorical predictor, along with other covariates. The mean duration of haemofilter circuit was 24.51 (24.08 to 29.08) hours without TPN and 17.22 (14.98 to 23.59) hours on TPN. With the maximal model, TPN use was significantly (P <0.002) associated with a decrease in duration of filtration, but none of the other factors were significant. There was a trend for platelet count to be significant.

Conclusions

So considering the effect sizes, both TPN and increase in platelet count were associated with significant reduction in the duration of haemofilter circuit by 7 hours. The effect of TPN was found to be independent of the platelet count.

P111 Effects of ultrafiltration on systemic hemodynamics and microcirculatory perfusion in patients with end-stage kidney disease

E Klijn, M Van Genderen, M Betjes, J Bakker, J Van Bommel

Erasmus MC University Medical Center, Rotterdam, the Netherlands

Introduction

The relationship between systemic hemodynamic parameters and microcirculatory perfusion remains unclear. This is especially apparent in the context of fluid responsiveness, where stroke volume (SV) can fluctuate strongly without being paralleled by changes in microcirculatory perfusion. Therefore, we hypothesized that large decreases in volume status due to ultrafiltration (UF) with intermittent hemodialysis in patients with end-stage kidney disease (ESKD) would decrease systemic hemodynamics but would not affect parameters of microcirculatory perfusion.

Methods

Consecutive patients on chronic intermittent hemodialysis for ESKD were eligible for our study. SV and heart rate were measured continuously and non-invasively using NICOM, a technique based on chest bioelectrical impedance. Blood pressure was measured intermittently with a sphygmomanometer. Peripheral and microcirculatory perfusion were measured intermittently with sidestream dark-field (SDF) imaging (sublingual area), and continuously with forearm-to-finger temperature gradient (△Tskin-diff) and photoplethysmography (PPG) (finger). All parameters were assessed before (baseline) and after 4 hours at the end of UF.

Results

Data are presented as median (IQR). Twenty-one patients (13 males, median age 59 (51 to 66) years) were included in our study. A median volume of 2,200 (1,850 to 2,850) ml was removed. SV and mean arterial pressure decreased during UF from 75 (58 to 84) mmHg to 51 (37 to 67) mmHg (P <0.01) and from 102 (88 to 109) mmHg to 85 (75 to 95) mmHg (P <0.001), respectively, while heart rate did not change. At baseline all parameters of peripheral and microcirculatory perfusion were undisturbed. During UF, Tskın-diff and the PPG of the finger did not change. Sublingual microvascular flow index and vessel density measured with SDF slightly decreased from 3.0 (3.0 to 3.0) to 2.8 (2.7 to 2.9) (P <0.001) and from 10.6 (9.9 to 11.1) n/mm to 9.9 (9.2 to 10.5) n/mm (P <0.05), respectively.

Conclusions

UF leads to a significant and uniform decrease in volume status in patients with ESKD but surprisingly this was not associated with large decreases in peripheral and microcirculatory perfusion. Therefore caution is warranted when interpreting systemic hemodynamic parameters in terms of hypovolemia and hypoperfusion when peripheral perfusion is not evidently impaired.
The median change in serum creatinine was +6% (IQR –24% to +17%) during the first 6 days after surgery. AKI developed in 32 (3.4%) and in 19 (2.0%) patients classified as Risk and Injury, respectively. AKI-D developed in 13 (1.7%) patients. Table 1 shows the AUC-ROC curve value for each model (P <0.001 for all data) for the prediction of AKI and AKI-D.

Conclusions The model of Thakar is the best predictor of AKI and AKI-D in our population.

Hypercalcemia during renal replacement therapy after liver transplantation

J Matsumi, H Morimatsu, K Morita
Okayama University Hospital, Okayama, Japan

Introduction Patients who suffer from acute kidney injury (AKI) show electrolyte abnormalities that can be corrected using renal replacement therapy (RRT). But some reports showed hypercalcemia during RRT and they reasoned this as the effect of citrate used for anticoagulant. We report eight post-liver transplantation (LT) recipients who suffered from AKI requiring RRT without citrate, but showed abnormal increase of ionized calcium (iCa) levels.

Methods We retrospectively identified the recipients who suffered from AKI requiring RRT after LT. Then we picked up those who had increased iCa over 1.25 mmol/l as hypercalcemia (group H). We compared these recipients with those who matched in graft–recipient weight ratio (G/R) and intraoperative transfusion (units/kg) as controls (group N). Data were expressed as means with standard deviations. Analyses were made using Student’s t test. We considered P <0.05 statistically significant.

Results Among 250 recipients who had undergone LT in our hospital, 12 recipients received RRT. All RRT patients received nafamostat mesilate for anticoagulation. Eight patients had increased iCa (group H). All recipients in group H died during their index hospitalization. Compared with group N, group H had a higher iCa (1.3 ± 0.1 vs. 1.1 ± 0.0 mmol/l) and total bilirubin (T.Bil; 17 ± 9 vs. 4 ± 0 mg/dl). See Table 1.

Conclusions We reported eight LT recipients who suffered from AKI and required RRT and had abnormally increased iCa levels without using citrate as anticoagulant. Only T.Bil was higher in the hypercalcemic group compared with the matched control. Because all of the eight hypercalcemic patients with CRRT died, this abnormality would be important for patient outcome.

References
for sepsis treatment. Here we describe the effectiveness of SHEDD-fA, which makes the best use of three principles for solute removal, in the treatment of severe sepsis.

**Methods.** Twenty-nine septic shock patients were analyzed retrospectively. SHEDD-fA was initiated after adequate fluid resuscitation and catecholamine support. Operation conditions were QF = 150 ml/minute, QF = 1,500 ml/hour (post-dilution) and QD = 300 to 500 ml/minute using an HD machine over 8 to 12 hours daily. For the purpose of maximizing cytokine adsorption efficiency, we used a large-size (2.1 m²) PMMA dialyzer.

**Results.** *Decrease in blood IL-6 level.* SHEDD-fA was performed for 3 days. The percentage of IL-6 removed from the blood was 84.4 ± 25.8% (mean ± SD; P <0.01; n = 25; Figure 1). In addition, we simultaneously assayed both inlet and outlet IL-6 and found a 21.0 ± 13.4% (P <0.01; n = 25) removal ratio, showing that IL-6 is effectively removed after one pass through the hemofilter. Moreover, depressed mononcytic HLA-DR ratio was improved from 40.6 to 51.9% in one typical case. *Hemodynamics and Pro/PLA/FO/IMPROVEMENT.* In 22 out of the 29 septic shock patients, significant decreases in the catecholamine index/mean blood pressure were observed 3 hours after the initiation of SHEDD-fA (P <0.01). In septic ARDS patients, Pro/PLA/FO was significantly improved at 1 hour (P <0.01). The improvement of the abovementioned parameters continued afterwards for 72 hours. As a result, 13 of 16 patients survived.

**Conclusions.** We propose the use of a large-size, cytokine-adsorbing hemofilter (PMMA or AN69 based membrane) and the selection of a suitable duration modality in the treatment of severe sepsis.

Model-based cardiovascular monitoring of large pore hemofiltration during endotonic shock in pigs

JA Revie¹, DJ Stevenson¹, JG Chase¹, LE Hann¹, GM Shaw², A Le Compte³, BC Lambermont¹, A Ghysen¹, P Kohi¹, T Desaive¹

¹University of Canterbury, Christchurch, New Zealand; ²Christchurch Hospital, Christchurch, New Zealand; ³University of Liège, Belgium

Critical Care 2011, Volume 15 Suppl 1

**Introduction.** The aim of this research is to test the ability of a model-based method to track disease-dependent hemodynamic changes in sepsis. Thus, subject-specific models of the cardiovascular system (CVS) are identified using measurements from a porcine model of septic shock with hemofiltration [1].

**Methods.** Hemodynamic measurements were recorded every 30 minutes in four (porcine model) trials of 4 hours. Animals received a 0.5 mg/kg endotoxin infusion over the first 30 minutes and underwent zero-balance continuous venovenous filtration with 0.7 m² large pore substrate (80 kDa cut-off) from 60 minutes onwards [1]. Subject-specific CVS models were fitted to 34 sets of data from the four trials. Each dataset represents a minimal set of measurements available in an ICU. Identified physiological model parameters and model outputs were compared with experimentally derived indices and measurements for validation.

**Results.** The model predicted the left and right ventricular end-diastolic volumes and maximum left and right ventricular pressures to mean absolute errors of 7.1% and 6.7%. Changes in the modelled right ventricular end systolic elastance and pulmonary vascular resistance compared well ($R = 0.68$ and $0.73$) with the same metrics derived experimentally (via caval occlusion manoeuvre and four-element Windkessel model) from an earlier study on right ventricular–vascular coupling [1]. Clinically, the systemic vascular resistance (SVR) model parameter decreased initially in all four pigs and stabilised to a level 26% (on average) below baseline during hemofiltration. Hyperdynamic states were observed in two pigs, where increases in left ventricular contractility were unable to counteract the loss in SVR, resulting in decreased mean arterial pressure (MAP) and increased cardiac output (CO) in the model, consistent with the experimental measurements. In contrast, for the other two pigs, increases in SVR after hemofiltration helped maintain MAP, with CO remaining relatively constant over the duration of these trials.

**Conclusions.** Subject-specific CVS models are capable of accurately capturing acute disease-dependent hemodynamic changes due to endotoxic shock in pigs using a minimal set of measurements that are available in a typical ICU setting.

Different effect of CVVHDF and coupled plasma filtration and adsorption on IL-6 and procalcitonin in sepsis

F Turani¹, M Falco¹, R Barchetta¹, F Candidi¹, A Marinelli¹, C Di Corato²

European Aurelia Hospital, Rome, Italy

**Introduction.** A decrease of IL-6 and procalcitonin (PCT) correlates with survival during sepsis [1]. Coupled plasma filtration and adsorption (CPFA) supports the renal function and removes proinflammatory mediators, but few clinical studies compare the effects of CPFA and CVVHDF, the standard of care in septic patients with renal failure [2]. The aim of this study is to evaluate whether CPFA and CVVHDF have a different effect on IL-6 and PCT in septic patients.

**Methods.** Seventy septic patients have been enrolled in this study. Fifty-five patients were submitted to CPFA. Every patient had four CPFA treatments (LINDA; Bellco-Mirandola, Italy) for 8 hours with Qb = 200 ml/minute, Q ultrafiltration = 30 ml/kg/hour and Q plasma = 20% of Qb. Fifteen septic patients submitted to CVVHDF were used as the control group. At T0 (basal), T1 (after 24 hours), T2 (after 72 hours), plasma IL-6 and plasma PCT was evaluated. ANOVA was used to compare changes during times study. P <0.05 was considered statistically significant.

**Results.** Tables 1 and 2 present the main results of this study. In the CPFA group at T2 IL-6 and PCT decreased to lower levels than T0, whereas in CVVHDF no significant change was observed. Hemodynamic data and adrenergic support improved more in the CPFA group than in the CVVHDF group.

**Conclusions.** CPFA seems more efficient then CVVHDF to remove either IL-6 or PCT and to improve hemodynamic status. Further studies are warranted to show whether these data may translate into a better clinical outcome.

Effectiveness of continuous venovenous hemofiltration using a polymethylmethacrylate membrane hemofilter judging from a multiplex suspension array system in septic shock patients

Y Sakamoto1, T Miyashiro, N Kurukata1, Tito2, T Inamura, A Nakashima1, M Yahata1, K Mashiko2, H Yokota1, T Oba2

1Saga University Hospital, Saga City, Japan; 2Rakuno Gakuen University, Sapporo, Japan; 1Chiba Kokusai Hospital, Nippon Medical School, Inzai, Japan; 2Microbial Chemistry Research Foundation, Tokyo, Japan

Introduction

Septic shock is a condition associated with diffuse coagulopathy and multiple organ failure, and frequently ends in death. The effectiveness of continuous venovenous hemofiltration using a polymethylmethacrylate membrane hemofilter (CVVHDF using PMMA) for critically ill patients has also been reported. This treatment was showed as cytokine adsorption therapy, but there are not so many reports in the world.

Methods

We treated 16 septic shock patients by CVVHDF using PMMA. The patients were checked for 17 kinds of cytokines (IL-1, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-17, TNFα, G-CSF, GM-CSF, IFNγ, MIP-1, MIP-1A/MCAF) using a multiplex suspension array system. We also checked the PMMA column.

Results

The average APACHE II score and the average sepsis-related organ failure assessment (SOFA) score were 25.8 ± 12.5 and 10.1 ± 3.3 (Bio-Plex™). The survival rate was 83.3%. One day after treatment by CVVHDF using PMMA, IL-1β (P = 0.0473), IL-6 (P = 0.0306), IL-5 (P = 0.0436), IL-7 (P = 0.0061), IL-12 (P = 0.0049), IL-13 (P = 0.0150), IL-17 (P = 0.00036), IFNγ (P = 0.00038) and TNFs (P = 0.0208) were significantly decreased. And 3 days after this treatment, IL-6 (P = 0.0498), GC-SF (P = 0.0144) and MCP (P = 0.0134) were significantly decreased.

Conclusions

Therapies aimed at blood purification, such as CVVHDF, continuous hemofiltration (CVVHF) and plasma exchange, have been reported to be effective for the removal of inflammatory cytokines and various mediators. Few reports have shown the influence of the column used for CVVHDF on the removal efficiency of the above-mentioned factors, although several columns have been used in CVVHDF. CVVHDF using PMMA has been reported to be effective for cytokine removal. Our findings suggest that many cytokines were decreased after CVVHDF using PMMA treatment. On the other hand, we checked adsorption of many sepsis-related factors on a PMMA column.

Catecholamine index is a simple and useful marker for bacteremic patients treated by polymyxin B hemoperfusion therapy

University of Occupational and Environmental Health, Japan, Kitakyushu City, Fukuoka, Japan

Introduction

Polyoxymycin B hemoperfusion therapy has been used for the treatment of sepsis to reduce blood endotoxin levels and a variety of inflammatory mediators. There are many reports that polymyxin B hemoperfusion therapy potentially improves circulatory dynamics and reduces mortality [1,2]. However, it is still controversial what is an important predictive factor to define the mortality. We analyzed a relationship between circulatory dynamics and mortality in our cases of polymyxin B hemoperfusion therapy.

Methods

From January 2007 to June 2010, 69 patients who received polymyxin B hemoperfusion therapy were retrospectively reviewed. Two child cases, six cases of 24-hour death and the seven cases in whom bacteremia was not detected by blood culture test were excluded. In total, for 54 patients information including characteristics, etiological microorganisms, circulatory dynamics (catecholamine index (CAI) and mean arterial pressure (MAP)), lactate concentration and mortality was investigated. We divided the patients into survivor and nonsurvivor groups and compared these two groups. The statistical analyses were performed by unpaired t test.

Results

Thirty-four patients (63.0%) survived and 20 patients (37.0%) died. Before polymyxin B hemoperfusion therapy, there were no significant differences in CAI, MAP and lactate concentration (CAI: 23.6 ± 26.5 (mean ± SD) vs. 34.0 ± 25.3, MAP: 69.7 ± 16.7 vs. 62.0 ± 16.7 mmHg, lactate: 4.0 ± 2.6 vs. 4.8 ± 3.6 mmol/l). But 2 hours after polymyxin B hemoperfusion therapy, only the CAI of the survivor group was significantly lower than in the nonsurvivor group (14.2 ± 14.1 vs. 30.4 ± 25.5; P < 0.01). However, MAP and lactate concentration did not show significant differences between the two groups (MAP: 80.1 ± 13.0 vs. 78.0 ± 15.4, lactate: 2.5 ± 1.3 vs. 3.6 ± 3.2). At 24 hours after polymyxin B hemoperfusion therapy, the CAI difference between the two groups was became more remarkable (6.09 ± 9.02 vs. 27.18 ± 29.31; P < 0.01).

Conclusions

The CAI after polymyxin B hemoperfusion therapy was highly related to mortality, although the CAI before that therapy was not. Polymyxin B hemoperfusion therapy improve the circulatory dynamics of most sepsis patients, but the efficacy of that therapy to decreasing catecholamine is one of the important prognosis predictors for bacteremic patients.

Re-evaluation of direct hemoperfusion with polymyxin-B immobilized fiber for severe sepsis and septic shock

NM Matsuo, T Ikeda, N Ikeda

Tokyo Medical University, Hachioji Medical Center, Tokyo, Japan

Introduction

The equivalency of continuous venovenous hemofiltration and intermittent hemodialysis (28) was described as a key recommendation of the Surviving Sepsis Campaign guidelines in 2008. However, there are some discrepancies associated with the evaluation of blood purification in severe sepsis and septic shock in Japan. Direct hemoperfusion with polymyxin-B immobilized fiber (PMX-DHP), developed and currently in use in Japan, has not yet been evaluated abroad. We performed a retrospective study to re-evaluate PMX-DHP for severe sepsis or septic shock patients in our ICU.

Methods

We enrolled 302 patients (survival (S) group: 201, nonsurvival (NS) group: 101) in whom PMX-DHP had been performed for severe sepsis and septic shock from 1994 to 2010. These patients were allocated into two groups: those who survived for at least 28 days after the start of PMX-DHP therapy (S group: 201 patients) and those who did not (NS group: 101 patients). Background factors (age, gender, APACHE II scores, sepsis-related organ failure assessment score, Goris multiple organ failure (MOF) score), hemodynamics (blood pressure, PaO2/FIO2 ratio, catecholamine requirement), inflammatory mediators (IL-6, IL-8, IL-1ra), endothelial-related markers (PAI-1, ELAM-1) and procalcitonin levels were examined in each group.

Results

On background factors, only the Goris MOF score showed a statistically significant difference among the groups. Blood pressure and the PaO2/FIO2 ratio both improved markedly immediately after PMX-DHP. Also, the average required amount of catecholamine decreased after PMX-DHP. IL-6 and IL-1ra levels decreased immediately after PMX-DHP in both groups, but these values before PMX-DHP did not show any statistically significant difference between the groups. PAI-1 levels showed a significant decrease after PMX-DHP in both groups.
Conclusions We confirmed an improvement in pulmonary oxygenation and hemodynamic parameters using PMX-DHP for severe sepsis and septic shock patients. The levels of various inflammatory mediators decreased using PMX-DHP, but we did not find any correlation between these changes and outcome.

Extended duration of direct hemoperfusion with polymyxin B-immobilized fiber column improves hemodynamics in patients with septic shock
C Yamashita, Y Takasaki
1Uwajima Social Insurance Hospital, Uwajima, Japan; 2Uwajima Municipal Hospital, Uwajima, Japan

Introduction Endotoxin adsorption therapy by direct hemoperfusion with a polymyxin B-immobilized fiber column (PMX-DHP) has been widely used in patients with septic shock in Japan. Many Japanese doctors use each PMX cartridge only for 2 hours; however, the mechanisms and optimal duration of PMX treatment remain unclear. We have performed PMX-DHP for longer than 2 hours to confirm that an extended duration of PMX-DHP for patients with septic shock would give significant improvements of hemodynamics.

Methods We performed an extended PMX-DHP on 13 patients whose hemodynamics did not achieve the target of mean arterial pressure (MAP) >65 mmHg and inotropic score <5.0 at the time point of 2 hours after PMX-DHP. Hemodynamic parameters such as MAP, heart rate and the dose of vasoactive agents were assessed before treatment, 2 hours after the start of PMX-DHP, immediately and 24 hours after completion of PMX-DHP. The following were also recorded during the study: microbiological data, the APACHE II score, the Sequential Organ Failure Assessment (SOFA) score and 28-day mortality.

Results APACHE II and SOFA scores were 26.0 ± 9.0 and 10.4 ± 3.0, respectively. The 28-day mortality rate was 15.4%. The average duration of PMX-DHP was 14.9 ± 7.5 hours. PMX-DHP was well tolerated and showed no side effect over extended duration in treatment. MAP was increased: 64.2 ± 8.8 mmHg (baseline), 79.7 ± 10.5 mmHg (2 hours after the start of PMX-DHP), 88.4 ± 13.8 mmHg (immediately after completion) and 89.8 ± 12.8 mmHg (24 hours after completion). The inotropic score was also decreased: 16.4 ± 9.2 (baseline), 13.5 ± 7.2 (2 hours after the start of PMX-DHP), 5.7 ± 6.8 (immediately after completion) and 2.8 ± 3.6 (24 hours after completion). These improvements for 2 hours were statistically significant (P < 0.01).

Conclusions The hemodynamics kept improving during extended duration of DHP with one PMX cartridge. And we could use these cartridges safely. Thus we suggest that an extended duration of PMX treatment affords beneficial effects and may contribute to improve the mortality of patients with septic shock.

Use of activated clotting time to monitor anticoagulation in patients receiving unfractionated heparin on renal replacement therapy
A Bidwai1, R Sundaram2
1RLUH, Liverpool, UK; 2RAH, Glasgow, UK

Introduction The aim of our study was to determine the correlation between activated clotting time (ACT) and APTT values in patients receiving unfractionated heparin (UFH) for renal replacement therapy (RRT).

Methods A retrospective analysis was made of case notes and laboratory data of 39 critically ill patients who were on UFH for RRT over a 1-year period. There were 183 paired APTT and ACT measurements done at the same time (29 patients). APTT was done at the laboratory and ACT was done at the bedside using an ACTALYKE monitor (Array Medical). Target APTT and ACT ranges for UFH during RRT were 45 to 55 seconds (control 27 to 32 seconds) and 250 to 270 seconds (control 180 to 220 seconds). Datasets were divided into three groups and the correlation coefficient (Pearson’s) was calculated using SPSS software.

Results Mean APTT was 129.5 ± 68.29 (range 25.6 to 360) seconds and mean ACT was 234.6 ± 47.02 (range 125 to 387) seconds. APTT and ACT values were divided into three datasets in a 3 x 3 table. There was no correlation between APTT and ACT values (kappa score being 0.12). There were more above-range APTT values (140/183) against above-range ACT values (36/183). See Table 1 and Figure 1.

Conclusions Our data demonstrate that monitoring of anticoagulation with UFH using ACT cannot be recommended.

Single-dose application of antithrombin III as alternative anticoagulation during extracorporeal therapy in critically ill patients with advanced liver cirrhosis: a retrospective data analysis
R Brunner, C Madl, W Druml, U Holzinger
Medical University of Vienna, Austria

Introduction Adequate anticoagulation is essential to achieve efficient and cost-effective renal and liver replacement therapy. However, critically ill patients with advanced liver cirrhosis are associated with low antithrombin III (ATIII) serum levels and increased tendency to both coagulation and bleeding disorder. Thus, we hypothesized that single-dose application of antithrombin III prolongs filter lifetime during renal and liver replacement therapy in critically ill patients with advanced liver cirrhosis without causing additional bleeding problems.

Methods In this retrospective study, data of 33 extracorporeal therapies in nine critically ill patients with advanced liver cirrhosis admitted to a medical ICU in 2007 and 2008 were analyzed. Included patients underwent either continuous renal replacement therapy (CRRT), intermittent hemodialysis (IHD) or liver replacement using the molecular adsorbents recirculation system (MARS) with single doses of ATIII as sole anticoagulant. Bleeding complications and filter lifetimes were used as outcome parameters.

Results Data were available for 13 CRRT, 14 IHD, and six MARS filters with total filter lifetimes of 661 (CRRT), 66 (IHD), and 42 hours (MARS), respectively. Mean filter lifetimes were 44.0 ± 27.9 (CRRT), 4.7 ± 1.6 (IHD), or 4.6 ± 12.6 hours (MARS). Fifteen percent (two out of 13) of CRRT filters, 7% (one out of 14) of IHD filters and 0% (zero out of six) of MARS filters were lost due to clotting of the dialysis circuit. New onset of bleeding was not observed during IHD, MARS and CRRT.

Safety of drotrecogin alfa (activated) treatment in patients with severe sepsis on renal replacement therapy without additional anticoagulation
L. Mirea, I. Luca Vasiliiu, R. Ungureanu, A. Balanescu, I. Grintescu
Clinical Emergency Hospital, Bucharest, Romania

Introduction Patients with sepsis-induced acute renal failure on continuous renal replacement therapy (CRRT), who receive heparin, may be at higher risk of bleeding when drotrecogin alfa activated (DAA) is administered in addition to standard anticoagulation, especially surgical patients. There are some previous observations that no additional anticoagulation is necessary during simultaneous DAA infusion and CRRT. The aim of this study was to evaluate the safety of CRRT during DAA infusion without additional anticoagulant therapy.

Methods An observational, prospective study was conducted in an adult ICU. Sixteen surgical patients with severe sepsis on CRRT were divided into two groups: group A (eight patients) with DAA infusion, group B (eight patients) without DAA infusion. Baseline demographics, APACHE II score, serious bleeding events, and in-hospital mortality were reported. CRRT was performed using the Multifiltrate® system, heparin-free continuous venovenous hemodialysis mode in group A. After the completion of the DAA infusion, intravenous standard heparin was administered for the remaining time on hemofiltration. In group B concomitant heparin was administered as necessary to achieve an aPTT of approximately 60 seconds.

Results The mean filter survival time (defined as the time until the circuit clotted) was 30 hours on DAA infusion versus 22 hours after DAA infusion in group A and 19.6 hours in group B. All survivors had recovery of dialysis-free renal function. The mean APACHE II score was 31.25 in group A and 22.12 in group B. Hospital mortality was 50% in group A (4/8) and 37.5% in group B (3/8); no mortality was attributed to bleeding. One case of severe thrombocytopenia was recorded with premature interruption of DAA infusion. The need for transfusion of blood and blood products infusion was compared (61% during DAA infusion vs. 52% after DAA infusion; 55% in group B); no serious bleeding event in both groups.

Conclusions The use of DAA in patients with severe sepsis requiring RRT is safe and is not associated with an increased of major bleeding events. No additional anticoagulation is necessary during simultaneous DAA infusion and CRRT.

Association between type of anticoagulation and blood transfusion requirements during renal replacement therapy in the ICU
A. Iyer, J. Ever, L. Tovey, H. Dickie, M. Ostermann
Guy’s & St Thomas’ Foundation Hospital, London, UK

Introduction Renal replacement therapy (RRT) is an essential component of modern critical care. Anticoagulation is necessary to prevent premature clotting of the extracorporeal circuit. We aimed to determine whether regional anticoagulation with citrate is associated with the reported reduced need for blood transfusions compared with heparin or epoprostenol.

Methods We retrospectively analysed all of the adult patients who received RRT in the general ICU at Guy’s & St Thomas’ Hospital, London between October 2008 and March 2009. Our first-line anticoagulation was heparin delivered via the circuit. It was clinical practice to maintain patients’ haemoglobin (Hb) at 8 g/dl. We calculated the number of units of red blood cells (RBC) transfused during the course of RRT and for 24 hours after.

Results In total, 156 patients were treated with RRT during the 6-month period. One hundred and forty-two patients received a single type of anticoagulation throughout the whole course of RRT (heparin via the circuit or systemically, n = 85; citrate, n = 12; epoprostenol, n = 45). Among patients without overt clinical bleeding episodes, the number of RBCs needed per day of RRT to maintain Hb at 8 g/dl was 0.5 units on citrate, 0.6 units on heparin and 0.6 units on epoprostenol (P = NS). Among 14 patients who had clinically recognized bleeding problems and did not change their anticoagulation, the requirements for RBC transfusion were 4.8 units/day in patients on heparin, 2.8 units/day on epoprostenol and 1.7 units on citrate (P = NS). In 11 patients, anticoagulation was changed during the course of RRT because of bleeding problems. Of the seven patients started on heparin, three were changed to citrate and four to epoprostenol. Four patients had a change from epoprostenol to citrate. Change from heparin to citrate resulted in reduced transfusion requirements from 0.8 units RBC per RRT day to 0.6 units per day (P = NS). Changing from heparin to epoprostenol was associated with a reduction from 8.1 to 0.73 units RBC per day on RRT (P = NS).

Conclusions Citrate-based anticoagulation for RRT in patients with contraindications to heparin was not associated with lower transfusion requirements.

P126
Economic argument for citrate haemofiltration
J. Patterson, D. Laia, M. Blunt
Queen Elizabeth Hospital, King’s Lynn, UK

Introduction Regional citrate anticoagulation is associated with increased mean filter life and greater completion of scheduled filter life compared with heparin [1]. Studies report mean filter lifespans of 44 hours [2] and that 80% of patients reach 72 hours [3]. The potential cost saving from this reduced filter kit purchase is only realised if the treatment is stopped due to filter clotting and needs to be recommenced. In order to identify this we set out to evaluate the filter life and stopping reason for CVVHf treatment in general critically ill patients.

Methods One hundred sequential patients receiving CVVHf were identified. For each patient, the number of treatments, filter life and reason for stopping treatment were recorded. A subset of treatments in which stopping was due to filter clotting and therapy resumed was identified. These were then analysed to see how many filtration sets could be saved if the filter life was 44 hours [2]. Sensitivity analysis was performed based on a 50% change in filter life improvement.

Results A total of 304 filter sets were used in 100 patients (one to 14 per patient) – median duration 18.3 hours (IQR 8.5 to 38.3) (Table 1). Cost analysis demonstrated 75 filters could be saved if filter lives were prolonged to 44 hours, equivalent to £4.01/treatment-hour (£3.26 to £5.03).

Multicenter prospective observational study on safety and efficacy of regional citrate anticoagulation in CVVHD in the presence of liver failure: the Liver Citrate Anticoagulation Threshold Study (L-CAT)
R Kalb1, J Ammann1, T Slowinski2, S Morgera2, D Kindgen-Milles1
1University Hospital, Düsseldorf, Germany; 2Charité, Berlin, Germany

Introduction Regional citrate anticoagulation in continuous venovenous hemodialysis (citrato-CVVHD) has become a widely used technique in the ICU, which decreases risk of bleeding. However, concern exists about safety of citrate in liver failure patients. The aim of our study was to evaluate safety and efficacy of regional citrate anticoagulation in ICU patients with normal and impaired liver function.

Methods One hundred and thirty-three ICU patients were prospectively observed for 72 hours of citrate-CVVHD. Patients were stratified into three groups according to their serum bilirubin (mg/dl) (normal: ≤2, mild: >2 to ≤7, severe: >7, n = 42). Citrate-CVVHD was performed with variable treatment dose using the multiFiltrate device (Fresenius Medical Care, Germany). End-points for safety were: severe acidosis or alkalosis (pH ≤7.2; ≥7.55) and severe hypocalcemia or hypercalcemia (≤0.9; ≥1.5 mmol/l) of any cause. End-point for efficacy was the filter lifetime.

Results Main types of ICU admission were: 56% medical and 38% post-surgery. Liver failure was predominantly due to ischemia (39%) or multiple organ dysfunction syndrome (27%). The frequency of safety end-points of any cause did not differ between the three patient strata: severe alkalosis (normal: 2%, mild: 0%, severe: 5%; P = 0.41); severe acidosis (normal: 13%, mild: 16%, severe: 14%; P = 0.95); severe hypocalcemia (normal: 8%, mild: 16%, severe: 12%; P = 0.57); severe hypercalcemia (0% in all strata). Only in three patients was an increased ratio of total to ionized calcium (≥2.5) detected (2%). Overall filter lifetime was 49% after 72 hours; however, after censoring for discontinuation due to non-clotting causes (for example, renal recovery, death) 96% of all filters were running after 72 hours.

Conclusions Our data demonstrate that citrate-CVVHD can be safely used in patients with liver dysfunction. Furthermore, it yields excellent filter patency and avoids bleeding, and thus can be recommended also in patients with liver dysfunction.

P128
Regional citrate anticoagulation in high-volume continuous venovenous hemodialysis
R Kalb1, J Ammann1, T Slowinski1, S Morgera1, D Kindgen-Milles1
1University Hospital, Düsseldorf, Germany; 2Charité, Berlin, Germany

Introduction Regional citrate anticoagulation (RCA) is a new anti-coagulation mode for continuous renal replacement therapy (CRRT). Compared with heparin anticoagulation, RCA prolongs filter lifetime, decreases transfusion requirements, and yields good metabolic control [1,2]. However, RCA was not investigated in patients requiring dialysis doses of >3 l/hour because of severe metabolic derangements or obesity. We investigated whether RCA for CVVHD is safe and effective also in patients in need of such intensified treatment. We focused on the filter lifetime, delivered dialysis dose, and control of acid–base balance.

Methods In a prospective observational study we enrolled 75 patients with acute kidney failure (AKF) following extended surgery. High-volume CVVHD was applied using RCA for at least 72 hours. Minimum dialysis dose was targeted at 45 ml/kg/hour. According to the protocol, for effective anticoagulation, a citrate dose of 4 mmol/l blood and a calcium infusion of 1.7 mmol/l/hour was required. We measured arterial blood gases and levels of ionized calcium pre-filter and post-filter every 4 hours. Blood flow, dialysis dose and doses of citrate and calcium were registered as well as filter lifetime and the reason for downtime.

Results The mean dialysis dose during the first 72 hours of treatment was 49 ± 14 ml/kg/hour, corresponding to a dialysate flow of 3,736 ± 88 ml/hour. Mean blood flow was 177 ± 4 ml/minute. The mean citrate dose applied during the first 72 hours was 3.83 ± 0.07 mmol/l. The mean calcium dose was 1.85 ± 0.06 mmol/l. Severe hypercalcemia/hypercalciemia did not occur. In one case an increasing demand for calcium substitution occurred after 84 hours that was indicative of citrate accumulation but the total/ionized calcium index was never higher than 2.5. After 72 hours of CVVHD, acidosis (pH <7.35) occurred in 7% (5/75) of all patients, an alkalosis (pH >7.45) in 22% (16/73) while 71% (52/73) showed a normal pH. Mean filter lifetime was 78 ± 2 hours. Thirteen treatments were stopped because of filter clotting, in all the remaining 87 filters stopping of treatment was caused by other reasons (surgery, diagnostic procedures, restored diuresis, death). There were no bleeding complications related to renal replacement therapy. In-hospital mortality was 57% (43/75).

Conclusions Regional citrate anticoagulation for CVVHD is safe and effective to deliver a high dialysis dose, to control acid–base status, and to yield excellent filter lifetimes in postoperative AKF.

Systemic citrate load during continuous renal replacement therapy is not negligible and can be predicted using indirect methods
M Zakharchenko1, M Balik1, M Othali1, J Hruby1, J Vavrov1, A Jabour1
1First Faculty of Medicine Charles University and General University Hospital, Prague, Czech Republic; 2University Hospital, Hradec Kralove, Czech Republic; 3KEM, Prague, Czech Republic

Introduction Data on significance of systemic gain of citrate during continuous renal replacement therapy (CRRT) are missing. Direct citrate measurements are scarcely available. The quantification using a difference of unmeasured anions (UA) on the filter and the method using correlation between concentration of citrate (Cf) in effluent to the proportion of citrate flow to blood flow (Qc/Qb) were compared with the control exact methods.

Methods A prospective controlled observational study was performed in a 20-bed general ICU. Patients on 2.2% acid-citrate-dextrose (ACD), n = 36 were compared with controls on unfractioned heparin (n = 17). All were treated with an Aquarius Baxter device on 1.9 m² polysulfone filters. Samples were taken from a central venous catheter, ports pre-filter and post-filter and from dialysate/effluent 24 hours after commencing with CRRT and 60 minutes later.

Results There were no significant differences (P >0.05) between CVVH (n = 18) and CVVHDF (n = 23) in measured citratemias nor in systemic gain of citrate. The difference between post-filter and pre-filter UA correlated with difference of citrate concentrations (r² = 0.66). Citrate gain was calculated as 31.5 ± 10.5 mmol/hour utilizing this relationship. Cf showed tight correlation with the Qc/Qb ratio (r² = 0.72). Gain of citrate calculated as citrate input minus citrate removal (effluent flow x Cf) where the regression equation replaces Cf was 29.4 ± 7.2 mmol/hour. The first exact method used post-filter and pre-filter citrate concentrations multiplied by matching blood flows. Gain of citrate obtained by this method was 29.3 ± 11.0 mmol/hour. The second exact method deducted citrate removal (15.7 ± 5.9 mmol/hour) in effluent from citrate input (45.1 ± 8.8 mmol/hour) and produced a citrate gain of 29.3 ± 7.2 mmol/hour. Comparing two studied methods of citrate gain estimation with exact methods showed no significant differences (P = 0.5, Kruskal–Wallis ANOVA). Bland–Altman analysis showed no systematic bias in results.

Conclusions Systemic load of citrate is not negligible and can be predicted without taking direct citrate levels. Proposed indirect methods showed reasonable accuracy in systemic citrate load estimation.

Use of 2-hourly creatinine clearance to inform renal replacement therapy
D Solyomo1; S Frohlich2; N Conlon1
1St Vincent’s University Hospital, Dublin, Ireland; 2St James’s Hospital, Dublin, Ireland

Introduction Acute kidney injury (AKI) is a common problem in critically ill patients, with a reported incidence of 1 to 25% and a poor prognosis. Although optimal dosing of renal replacement therapy (RRT) is relatively well understood, appropriate timing of commencing and ceasing RRT in patients with AKI has been under debate for a long time. From the viewpoint of an early renal support strategy, the goal of early RRT is to maintain solute clearance and fluid balance to prevent subsequent multiorgan damage, while waiting for the recovery of renal function. It has previously been noted that 2-hourly creatinine clearance accurately reflects the more cumbersome 24-hour value.

Methods Twenty-one patients diagnosed with ARDS were included in our study. ARDS was defined according to the NHBLI ARDS Network Treatment Protocol. Creatinine clearance was calculated daily on most patients of RRT in our ICU. If CrCl is greater than 20 ml/minute, CRRT is ceased. Our retrospective chart review examined records for all patients admitted to our ICU in 2008 and determined whether a CrCl greater than 20 ml/minute accurately predicted remaining dialysis-free 5 days later.

Results Forty-one patients were suitable for analysis. Of these, 12 (30%) never reached CrCl >20 ml/minute and remained on dialysis leaving the ICU. Of the remaining 29 patients, in 23 (79%) having a CrCl >20 ml/minute meant they remained dialysis-free for at least the following 5 days. Six patients (21%), despite having a CrCl >20 ml/minute, resumed dialysis within 5 days for metabolic or fluid-removal reasons.

Conclusions Although this is a small retrospective study it suggests that 2-hourly creatinine clearance values may accurately predict when CRRT should be discontinued. These pilot results should be used to inform a larger prospective study.

NT-proBNP, troponin I and troponin T are elevated in ARDS patients without structural heart disease: a single initial reading of cardiac markers is sufficient from serial daily readings
Y Nassar, D Monsel, S Abdelshafy, G Hamed
Cairo University, Cairo, Egypt

Introduction Myocardial injury and cardiac marker elevation may occur in ARDS patients without a structural heart disease, which might affect cardiac markers [1,2].

Methods The study was conducted in Cairo University Hospital between 1 June 2008 and 1 April 2009. The inclusion criterion was any adult patient diagnosed to have ARDS according to the criteria of the American-European Consensus Conference of 1994. Exclusion criteria were any pre-existing structural heart disease, pulmonary embolism, atrial fibrillation, renal insufficiency, age <18. Plasma levels of cardiac markers NT-proBNP, troponin I and troponin T were measured on day 0 and on day 2 and day 7 of ARDS diagnosis. All patients benefited from mechanical ventilation with a lung-protective ventilation strategy according to the NHBLI ARDS Network Treatment Protocol.

Results The study comprised a total of 20 patients with mean age of 58.9 ± 20.69 years, 11 men versus nine women (P > 0.05). The ARDS aetiology was five (25%) patients due to sepsis, four (20%) due to pneumonia, three (15%) aspiration, three (15%) lung contusions due to road traffic accidents (RTA), two (10%) drug overdose, one (5%) burns, one (5%) pancreatitis, one (5%) drowning. NT-proBNP mean values were 8,903.3 ± 12,852.8 versus 6,083.6 ± 8,467.9 versus 9,914.8 ± 12,574.1 on day 0, day 2 and day 7, respectively (P > 0.05). Troponin I mean values were 3.0 ± 7.7 versus 2.2 ± 6.6 versus 1.5 ± 4.4 on day 0, day 2 and day 7, respectively (P > 0.05). Troponin T mean values were 0.3 ± 0.6 versus 0.3 ± 1.5 versus 0.5 ± 1.1 on day 0, day 2 and day 7, respectively (P > 0.05).

Conclusions ARDS patients with structurally normal hearts show persistent elevated levels of cardiac markers NT-proBNP, troponin I and troponin T over the first week with no significant change between levels of day 0, day 2 and day 7. A single reading of cardiac markers on any day of the first week of ARDS may not be different from serial daily readings.

References
this audit was therefore to assess whether the implementation of the blood investigation order chart reduced the number of blood tests performed and the associated costs.

Methods Data on the numbers and types of blood investigations were collated for all patients with a length of stay greater than 24 hours in our six-bed critical care unit. The audit period covered 100 days prior to implementation of the order chart and 100 days post implementation. The blood tests assessed were: full blood picture (FBP), urea and electrolytes (U&E), coagulation screen, liver function tests (LFT), magnesium, bone profile (Ca, PO, and albumin), and C-reactive protein (CRP). A comparative analysis of the numbers, types and costs of blood testing pre and post implementation was conducted. The study did not seek to assess patient outcomes mainly due to the small number of patients involved.

Results The implementation of the ordering chart resulted in a reduction in the number of blood investigations ordered, from a total of 2,209 pre implementation to 1,477 post implementation; that is, a 33% net reduction. The tests that showed the largest reductions were coagulation screens, LFT and bone profiles, with reductions of 52%, 54% and 53%, respectively. A moderate reduction was observed in magnesium and CRP tests, at 43% and 21% respectively. Only a very small reduction in the number of FBP and U&E tests was found. When the financial costs of these reductions were assessed, the analysis showed an overall saving for the ICU of £17,914 per annum, or £2,986 per bed.

Conclusions The results of this audit suggest that the implementation of simple low-cost measures, such as a blood investigation order chart to specify and customise blood testing in the ICU, can significantly reduce the costs associated with patient stay in the ICU.

Contribution of red blood cells to the compensation for hypocapnic alkalosis through plasmatic strong ion difference variations

T Langer, L Zani, E Carlesso, A Protti, P Caironi, M Chierichetti, ML Caspani, T Langer, L Zani, E Carlesso, A Protti, P Caironi, M Chierichetti, ML Caspani, L Gattinoni
Università degli Studi di Milano, Milan, Italy

Introduction Chloride shift is the movement of chloride between red blood cells (RBC) and plasma (and vice versa) caused by variations in pCO₂. The aim of our study was to investigate changes in plasmatic strong ion difference (SID) during acute variations in pCO₂, and their possible role in the compensation for hypocapnic alkalosis.

Methods Patients admitted in this year to our ICU requiring extracorporeal CO₂ removal were enrolled. Couples of measurements of gases and electrolytes on blood entering (v) and leaving (a) the respiratory membrane were analyzed. SID was calculated as [Na⁺] + [K⁺] + [2(Ca²⁺) – [Cl⁻] – [Lac⁻]]. Percentage variations in SID (SID%) were calculated as (SID v – SID a) x 100 / SID v. The same calculation was performed for pCO₂ (pCO₂%). Comparison between v and a values was performed by paired t test or the signed-rank test, as appropriate.

Results Analysis was conducted on 205 sample-couples of six enrolled patients. A significant difference (P <0.001) between mean values of v–a samples was observed for pH (7.41 ± 0.05 vs. 7.51 ± 0.06), pCO₂ (48 ± 6 vs. 35 ± 7 mmHg), [Na⁺] (136.3 ± 4.0 vs. 135.2 ± 4.0 mEq/l), [Cl⁻] (101.5 ± 3.5 vs. 102.8 ± 5.2 mEq/l) and therefore SID (39.5 ± 4.0 vs. 36.9 ± 4.1 mEq/l), pCO₂% and SID% significantly correlated (r² = 0.28, P <0.001). Graphical representation by quartiles of pCO₂% is shown in Figure 1.

Conclusions As a reduction in SID decreases pH, the observed movement of anions and cations probably limited the alkalization caused by hypocapnia. In this model, the only source of electrolytes are blood cells (that is, no interstitium and no influence of the kidney is present); it is therefore conceivable to consider the observed phenomenon as the contribution of RBC for the compensation of acute hypocapnic alkalosis.

Interactive visual analysis of a large ICU database: a novel approach to data analysis

H Gan¹, K Matkovic², A Ammer³, W Purgathofer⁴, D Bennett⁵, M Terblanche⁶
¹Guy’s & St Thomas’ Hospital, London, UK; ²VRVIS Research Centre, Vienna, Austria; ³King’s College London, London, UK

Introduction ICUs generate vast amounts of valuable data. The size and complexity of the data make analysis technically demanding and time-consuming. We used interactive visual analysis (IVA) to analyse a large ICU database using the association between sodium and mortality as a case study.

Methods We analysed routinely collected longitudinal clinical ICU data using ComVis⁶, an IVA tool developed for research in nonmedical fields. Coordinated multiple views enable the simultaneous visualisation of multiple variables of any data type (including time series). Individual variables and relationships between multiple variables are displayed in multiple linked views using user-selected box plots, histograms, scatter-plots, time series, parallel coordinates, and so forth. Visually selecting data by brushing with the cursor simultaneously highlights corresponding data in all other views. Multiple brushes are combined using Boolean logic, and the new selection is automatically updated across all views. We used IVA to analyse the univariate effect of sodium (Na) longitudinal trends (and rate of change) on mortality in 1,447 ICU patients. We defined high sodium as >150 mmol/l, low Na as <130 mmol/l, and a rapid rise and fall as a change >3 mmol/l/hour at any time. Trends of interest were identified using IVA while OR and P values were calculated using standard statistical techniques.

Results Overall ICU mortality was 22.5% (95% CI = 0.20.3 to 24.7%). Mean Na was 140 mmol/l (SD 4.3, within-patient minimum and maximum 123 and 166). Mortality was associated with: high Na versus Na <150 (28.6% vs. 20.9%, OR = 1.5, P = 0.004); rapid Na fall versus no rapid fall (27.6% vs. 17.7%, OR = 1.8, P <0.001); and rapid Na rise versus no rapid rise (27.6% vs. 17.7%, OR = 1.8, P <0.001). In contrast, low Na versus Na >130 (24.8% vs. 21.9%, OR = 1.2, P = 0.3); low Na with a rapid rise versus low Na with no rapid rise (26.3% vs. 20.7%, OR = 1.4, P = 0.3) and high Na with a rapid fall versus high Na with no rapid fall (30.6% vs. 24.2%, OR = 1.4, P = 0.3) were not associated with mortality.

Conclusions IVA facilitates a visual approach to data analysis that is both intuitive and efficient. This hypothesis can first be explored visually before further analysis using conventional statistical methods. Advanced statistical modeling can be used to confirm any potential hypothesis identified by visual analyses.

Università degli Studi di Milano, Milan, Italy

Introduction Chloride shift is the movement of chloride between red blood cells (RBC) and plasma (and vice versa) caused by variations in pCO₂. The aim of our study was to investigate changes in plasmatic strong ion difference (SID) during acute variations in pCO₂, and their possible role in the compensation for hypocapnic alkalosis.

Methods Patients admitted in this year to our ICU requiring extracorporeal CO₂ removal were enrolled. Couples of measurements of gases and electrolytes on blood entering (v) and leaving (a) the respiratory membrane were analyzed. SID was calculated as [Na⁺] + [K⁺] + [2(Ca²⁺) – [Cl⁻] – [Lac⁻]]. Percentage variations in SID (SID%) were calculated as (SID v – SID a) x 100 / SID v. The same calculation was performed for pCO₂ (pCO₂%). Comparison between v and a values was performed by paired t test or the signed-rank test, as appropriate.

Results Analysis was conducted on 205 sample-couples of six enrolled patients. A significant difference (P <0.001) between mean values of v–a samples was observed for pH (7.41 ± 0.05 vs. 7.51 ± 0.06), pCO₂ (48 ± 6 vs. 35 ± 7 mmHg), [Na⁺] (136.3 ± 4.0 vs. 135.2 ± 4.0 mEq/l), [Cl⁻] (101.5 ± 3.5 vs. 102.8 ± 5.2 mEq/l) and therefore SID (39.5 ± 4.0 vs. 36.9 ± 4.1 mEq/l), pCO₂% and SID% significantly correlated (r² = 0.28, P <0.001). Graphical representation by quartiles of pCO₂% is shown in Figure 1.

Conclusions As a reduction in SID decreases pH, the observed movement of anions and cations probably limited the alkalization caused by hypocapnia. In this model, the only source of electrolytes are blood cells (that is, no interstitium and no influence of the kidney is present); it is therefore conceivable to consider the observed phenomenon as the contribution of RBC for the compensation of acute hypocapnic alkalosis.
Base excess can be misleading in acute respiratory acidosis
S Koci, K Kiss, B Szendahelyi, M Demeter, Z Molnar
University of Szeged, Hungary

Introduction Base excess (BE) is the measure of nonrespiratory change of acid–base status in the body. It is calculated after correcting the blood sample’s pH to 7.4, temperature to 37°C and pCO2 to 40 mmHg. Actual HCO3 level is a metabolic parameter derived directly from the Henderson–Hasselbalch equation. There is some evidence that the relationship between BE and HCO3 is critically ill patients immediately after admission to the ICU.

Methods The first arterial blood gas samples (within 1 hour of admission) of patients admitted to our ICU were retrospectively evaluated and pH, HCO3, pCO2, and BE were registered and analysed. After testing the data distribution, correlation was determined with Pearson’s correlation.

Results Arterial blood gas samples from 88 patients were analysed. There was a strong, significant correlation between BE and HCO3 (r² = 0.93, P < 0.001) in the whole sample. In blood samples with pCO2 >45 mmHg, in 26 cases the pH was >7.3, and in 15 cases pH was <7.3 (that is, acute respiratory acidosis). In these cases with a cut-off BE <0 mmol/l, the BE had sensitivity = 73% and specificity = 85% for predicting acidosis. With a cut-off for HCO3 >24 mmol/l, the HCO3 had sensitivity = 27% and specificity = 100% for acidosis. Choosing a cut-off for BE <–2 mmol/l, sensitivity = 47%, specificity = 100%; for HCO3 <22 mmol/l, sensitivity = 13%, specificity = 100%.

Conclusions Although BE and HCO3 had very good correlation in the whole sample, in acute respiratory acidosis BE indicated metabolic acidosis with high sensitivity, while the high specificity and low sensitivity of HCO3 showed that there was no metabolic component of the acid–base imbalance. Therefore, in accord with previous studies, our preliminary results give further evidence that HCO3 is a more reliable parameter to analyse acid–base balance in acute circumstances, especially in acute respiratory acidosis, than BE.

Prescription and clinical impact of chest radiographs in 104 French ICUs: the RadioDay Study
MS Serveaux-Delouis1, K Lakhal1, X Capdevi1a, JY Lefrant1, S Jaber1
RadioDay Study Group1
1CHU Lapeyronie, Montpellier, France; 2CHU Caremeau, Nimes, France; 3CHU Saint Eloi, Montpellier, France

Introduction Prescribing daily routine chest radiographs (CXRs) in ICU patients is a matter for debate. We aimed at describing current strategies of CXR prescriptions and their diagnostic and therapeutic impacts in a large panel of French ICUs.

Methods We performed a postal survey recording ICU habits of CXR prescription and a snapshot single-day (called RadioDay) observational study analyzing all of the prescribed CXRs.

Results Survey (n = 104 ICUs) CXR prescription was made on a daily routine basis for every patient and only in mechanically ventilated patients in 7% and 37% of the 104 ICUs, respectively. Depending on the ICUs, ICU admission (55% of the ICUs), endotracheal intubation (87%), tracheostomy (87%), superior vena cava device (96%), nasogastric tube (48%), chest tube insertion (98%) and chest tube removal (60%) were systematically followed by a CXR. A written procedure for CXR prescription was available in 12% ICUs. Snapshot study On RadioDay, 854 CXRs were performed (8.2 ± 4.6 per center) in 804 patients: 36.5% were prescribed on a daily routine basis. The most frequent indications for on-demand CXR were: follow-up of pleuropulmonary pathology (32%), control after invasive device placement (20%), search for an etiology of respiratory or circulatory failure (13%) and ICU admission (11%). On-demand CXRs were mostly (62%) performed during the morning round. On-demand CXR showed more frequently a tissue abnormality than daily routine CXR (69% vs. 48%, P < 0.001) and this radiographic finding was unexpected in 20 and 15%, respectively (P = 0.22). On-demand CXR was more frequently associated with treatment modification (which would not have occurred without the CXR) than daily routine CXR (38% vs. 19%, P < 0.001): placement/ modification/or removal of an invasive device (18 vs. 9%, P < 0.001), prescription of another paraclinical investigation (15 vs. 3%, P < 0.001), initiation/continuation/or discontinuation of medications (25 vs. 11%, P < 0.001). CXR findings were expected and had no impact on management in 56 and 77% (P < 0.001) of the on-demand and daily routine CXR, respectively.

Conclusions There is an obvious lack of consensus for CXR prescription in French ICUs. The clinical impact of on-demand CXR is higher than that associated with a daily routine prescription.

Intraosseous blood aspirates analysed by a portable cartridge-based device
G Strangberg1, A Larsson1, M Lipscey1, M Eriksson1
1Anesthesia & Intensive Care, Uppsala University, Sweden; 2Clinical Chemistry, Uppsala University, Sweden

Introduction Intraosseous (IO) needles play an important role in medical emergencies, when venous access is difficult to establish. IO needles are suitable for infusion, but their use for blood sampling has been questioned, since aggregates of marrow substances may block analysers [1]. However, portable laboratory instruments have been developed, where the blood may be analysed within a separate cartridge. We decided to evaluate whether such a portable device is suitable for analysis of blood gases and electrolytes in aspirates obtained from IO needles during a 6-hour period. A second aim of this study was to compare such IO aspirates with arterial blood samples, both of them analysed by a handheld laboratory analysis system.

Methods IO needles (Im-Medico) were inserted bilaterally in the proximal tibiae of five anaesthetised healthy pigs. Blood gases and electrolytes (Na, K, Ca) were taken hourly. IO aspirates and arterial blood samples were immediately analysed by an i-STAT handheld (Abbott Point of Care) equipped with EG+ and CG+ cartridges. A coefficient of variance (CV) >20%, was regarded as the upper limit of quantification [2]. Bland–Altman curves were used to assess agreement between the two methods [3].

Results Repeated IO aspirates were easily obtained during the entire 6-hour period. There were excellent consistencies in blood gases and electrolytes, between IO aspirates from the left and right tibiae, except for BE, where CV >20%. IO aspirates were compared with arterial samples. There were compliant values between these sources regarding electrolytes, Hb, pH, pCO2 and SBC. This was in contrast to BE, lactate, PO2 and SO2, which all exhibited CV >20%. Although both SO2 and PO2 were higher in arterial samples as compared with IO samples, there were high correlations between these two variables in arterial blood and IO aspirates (R² = 0.9; P < 0.001 and R² = 0.7; P < 0.001, respectively). There were only minor changes over time in any of these variables during the entire experimental period.

Conclusions Blood gases and electrolytes in IO blood aspirates are easily analysed by a handheld device during a 6-hour period. The development of this cartridge-based laboratory analysis system strengthens the concept of using IO needles as a valuable tool in medical emergency situations. If blood gases are to be evaluated in IO aspirates, SBC seems to reflect arterial conditions better than BE does.

Capnography activation is improved by better ventilator interface ergonomics

E Hodge, M Blunt, P Young

Queen Elizabeth Hospital, King’s Lynn, UK

**Introduction**

In critical care, capnography is recommended [1]. Upon intubation this is important to rapidly confirm endotracheal tube position. Often capnography is built into critical care ventilators, but as these are frequently used for non-invasive ventilation it is necessary that this monitoring may be switched off and on. We postulated that the ease with which this could be done would relate to the ergonomic design of the ventilation interface and compared the Drager Evita 4 and Drager V500. The Evita 4 has a button hidden within the alarm limits section, whereas on the V500, which has locally configurable interface, this had been placed on the main screen.

**Methods**

Thirty-one nursing and medical ICU staff were studied. The ventilator was set up in a controlled mode with the default front screen visible with capnography disabled. The time to successful activation of capnography was recorded. Each subject performed the same test on both ventilators in a randomized crossover design.

**Results**

More subjects failed to activate capnography within 120 seconds with the Evita 4 compared with the V500 (14 vs. 1) and survival analysis identified significantly faster time to successful activation in the V500 (see Figure 1). Analysis identified no period effect due to the crossover design.

**Conclusions**

Despite the extensive experience and training on the Evita 4, many subjects were not able to activate capnography within 2 minutes; however, by configuring the screen of the V500 this was almost eliminated in staff even without specific training. Immediate availability of capnography is an important safety issue and manufacturers should consider this in the ergonomic design of their equipment interfaces.

Impact of cardiac arrest duration on extravascular lung water and pulmonary vascular permeability index in patients with postcardiac arrest syndrome: a prospective observational study

T Tagami¹, R Tosa¹, M Omura¹, J Hagiwara¹, N Kido¹, H Hirama¹, H Yokota²

¹Aidu Chuo Hospital, Aizuwakamatsu, Fukushima, Japan; ²Nippon Medical University, Bunkyo, Japan

**Introduction**

Pulmonary dysfunction after cardiac arrest is a common phenomenon. Evidence appears to support the usefulness of quantitative assessment of pulmonary dysfunction using extravascular lung water (EVLW) and the pulmonary vascular permeability index (PVPI).

We hypothesized that the duration of cardiac arrest (CPA TIME) would impact the pulmonary dysfunction in patients with postcardiac arrest syndrome. The aim of the present study was to investigate the lung dysfunction quantitatively using EVLW and PVPI in successfully resuscitated patients after cardiac arrest (CPA).

**Methods**

This was a prospective observational study of 106 (59 male, 47 female) postcardiac arrest syndrome patients. Eligible patients included all who were in CPA on arrival at the hospital and experienced effective resuscitation resulting in resumption of spontaneous circulation. All patients were resuscitated per therapeutic protocol in our hospital. The CPA TIME from the scene was recorded. The patients were divided into two groups by the cause of CPA: cardiogenic (CG) or noncardiogenic (NCG). Thermodilutional EVLW and PVPI measurements were performed using the PICCO monitoring system (Pulsion Medical Systems, Munich, Germany) as soon as the patients were admitted to the ICU.

**Results**

A moderate positive correlation was documented between the CPA TIME, EVLW ($r = 0.36$, $P < 0.001$) and PVPI ($r = 0.43$, $P < 0.001$) in all 106 patients. In the CG group, we found a very close positive correlation between the CPA TIME, EVLW ($r = 0.52$, $P < 0.001$) and PVPI ($r = 0.75$, $P < 0.001$). No correlations were documented between the CPA TIME, EVLW ($r = 0.25$, $P = 0.05$) and PVPI ($r = 0.24$, $P = 0.06$) in the NCG group.

**Conclusions**

The duration of cardiac arrest impacts on the increase in the EVLW and PVPI, especially in patients with CG postcardiac arrest syndrome.

Indexed extravascular lung water to predicted body weight increases the correlation with lung injury score in patients with acute lung injury/acute respiratory distress syndrome: a prospective, multicenter study conducted in a Japanese population
H Fukushima, T Seki, Y Urizono, M Hata, K Nishio, K Okuchi
Nara Medical University Hopital, Kashihara City, Japan

Introduction
Since predicted body weight derived from height and gender reflects lung size better than actual body weight, it is suggested that extravascular lung water indexed to the predicted body weight (EVLWIp) is more closely related to severity of illness and mortality than EVLWI indexed to the actual body weight (EVLWIa). However, the usefulness of EVLWIp has not been evaluated in a multicenter study or in the Asian population.

Methods
We conducted a prospective, multicenter observational study in Japan with the following inclusion criteria: adult (≥18 years) patients needing mechanical ventilation, PaO2/FiO2 ratio below 300, and acute bilateral infiltrates in both lung fields on chest X-ray. The diagnosis of acute lung injury/acute respiratory distress syndrome (ALI/ARDS) was based on the usual criteria. Predicted body weight was calculated as 20 (for male) or 45.5 (for female) kg + 0.91(height in centimeter) – 12.24. BMI was defined as 18.5 to 22.9. Obesity was defined as BMI ≥ 25. Data are presented as medians and interquartile ranges (IQR). A Wilcoxon’s rank sum test and the Mann–Whitney test were used to compare the values, and correlations were analyzed using Spearman’s rank correlation coefficient. Statistical significance was tested at a level of 0.05.

Results
Seventy-eight patients with ALI/ARDS were enrolled. The values of EVLWIp (17.1 ml/kg; IQR 12.9 to 21.4) were not different from EVLWIa (16.6 ml/kg; IQR 12.3 to 21.7). Although the overall correlation with APACHE II score, SOFA score, or mortality was not stronger for EVLWIp compared with EVLWIa, patients weighing under or over the normal range (BMI < 18.5 or BMI ≥ 23, 41 patients), EVLWIp was more closely correlated with Lung Injury Score (LIS) than EVLWIa (EVLWIp: r = 0.228, P = 0.152 vs. EVLWIa: r = 0.333, P = 0.033). Furthermore, in patients with BMI ≥ 25 (19 cases), the correlation of EVLWIp with LIS was much higher (r = 0.611, P = 0.005) compared with EVLWIa (r = 0.283, P = 0.240).

Conclusions
Even in the Japanese population, EVLWIp is more highly correlated to the LIS, especially in obese patients.

Feasibility of continuous exhaled breath analysis in intubated and mechanically ventilated critically ill patients
LD Bos, PJ Sterk, MJ Schultz
Academic Medical Center, Amsterdam, the Netherlands

Introduction
Pulmonary elimination of volatile molecules (so-called volatile organic compounds (VOCs)) is altered in a variety of pulmonary and nonpulmonary diseases [1]. Because breath of intubated and mechanically ventilated critically ill patients is continuously available, detection of changes in VOC patterns could be used to monitor these patients. We hypothesized that an electronic nose (eNose) provides a reliable and continuous read-out of changes in patterns of exhaled VOCs (so-called breathprints).

Methods
An observational pilot study of six intubated and mechanically ventilated critically ill patients. Breathprints were collected by means of an eNose every 10 seconds for ±7 hours. The patient sample size is too small for statistical analysis between patients, but varying fluctuations could be analysed within each patient.

Results
Breathprints fluctuated considerably over time (SEM 1.18). However, typical changes could be detected: for example, salbutamol inhalation, decreased static compliance and increased minute volumes all caused a rapid change in the breathprints (illustrated in Figure 1).

Conclusions
Continuous monitoring of exhaled breath using an eNose is feasible in intubated and mechanically ventilated patients. Our data suggest that changes of breathprints within patients could be used to assess the clinical course of the patients.

Pattern of cytokines and chemokines in exhaled breath condensate is related to the characteristics of mechanical ventilation
LD Bos, E Van Waltenshuis, J Van Houte, G Rijksen, H Van Velzen-Bladt, H Endeman
1 Diaconessenhuis, Utrecht, the Netherlands; 2 St Antonius Hospital, Nieuwegein, the Netherlands

Introduction
Ventilator-associated lung injury (VALI) is an inflammatory response of the lung caused by mechanical ventilation (MV) and is related to tidal volumes (TV), positive end-expiratory pressure (PEEP) and peak pressures (Ppeak) [1]. In experimental settings, VALI is characterized by a local inflammatory response measured in tissue or lavage. It is difficult to obtain this material in the critically ill [2]. Exhaled breath condensate (EBC) is obtained in patients on MV using an easy non-invasive technique. In this pilot study we examined the relation...
between levels of inflammatory proteins in EBC of patients on MV and characteristics of MV. 

**Methods** A prospective study was performed in 13 patients on MV. EBC was obtained from the connection-swiffle between ventilator and tube. IL-1β, IL-4, IL-6, IL-8, IL-10, IL-12, IL-17, IFNγ, MCP-1 and MIP-1β were determined by multiplex immunoassay. Levels of inflammatory mediators were correlated with parameters of MV.

**Results** In 13 (seven males) patients, 29 samples were obtained. Median age of the patients was 69 years, median APACHE II score 25 points. Sampling was taken during MV, even during pressure control (PC) and 22 during pressure support (PS) mode. Median Ppeak was 18 cmH₂O, median PEEP 8 cmH₂O, median TV 7.22 ml/kg and median P/F ratio 33.62 kPa. Levels of all inflammatory proteins except for IL-12 were lower in patients on PC, reaching statistical significance for IL-17 (median Ppeak ≤20 cmH₂O 0.00 vs. >20 cmH₂O 6.23, P = 0.033). Signifi cant lower levels were found in patients ventilated with TV ≤8 for MCP-1 (median TV ≤8 ml/kg 0.75 vs. TV >8 ml/kg 3.41, P = 0.032) and MIP-1β (median TV ≤8 ml/kg 0.00 vs. TV >8 ml/kg 1.96, P = 0.002). Levels of cytokines were lower in case of low Ppeak (≤20 cmH₂O) reaching the level of statistical signifi cance for IFNγ (median Ppeak ≤20 cmH₂O 0.00 vs. >20 cmH₂O 6.23, P = 0.025).

**Conclusions** In a small group of patients, cytokine and chemokine patterns in EBC were related with characteristics of MV. MV with a TV ≤8 may limit infl ammatory response.

**Divergent changes in regional pulmonary fi lling characteristics during endotoxin-induced acute lung injury in pigs**

A Amerni1, S Sondergaard1, A Fagerberg3, H Einarsen2

1Liverpool Hospital, Sydney, Australia; 2Sahlgrenska University Hospital, Gothenburg, Sweden

**Introduction** Divergent regional fi lling characteristics of the lung may explain ventilator-induced lung injury. In this descriptive study, the potential of electrical impedance tomography (EIT) to determine progressive changes in regional fi lling characteristics during acute lung injury was explored.

**Methods** Endotoxin was infused during 150 minutes in 11 mechanically ventilated pigs (VC, TV 10 ml/kg, PEEP 5, RR set to normocapnia at IE 1:2). EIT (Evaluation Kit 2; Dräger Medical) was used to monitor global and regional (four equal ventrodorsal regions of interest, ROIs 1 to 4) impedance changes at the mid-thoracic level. The tidal regional versus global impedance changes were normalized and analysed by second-degree polynomial correlation [1]. A square coefficient (r²) < 0 indicates hyperinflation, > 0 indicates recruitment and a value around 0 indicates homogeneous regional to global fi lling. Statistical evaluation was by ANOVA and Kruskal–Wallis post-hoc test, signifi cance was set at P < 0.05.

**Results** Endotoxinaemia increased the A–a O₂ gradient and shunt, Qs/Qt, from 5.7 ± 3.6 to 33 ± 24 kPa and from 9.2 ± 2 to 27 ± 6%. Homogeneous fi lling in all four ROIs occurred at baseline (Figure 1) but progressively changed to hyperinflation in ROI 1 (x² = 0.36) and recruitment (x² = 0.66) in ROI 4 at 150 minutes, with ROIs 2 and 3 showing intermediate but similar changes. The x² gradient from ROIs 1 to 4 (dotted line) increased signifi cantly consistent with increased regional heterogeneity comprising hyperinfl ation as well as recruitment.

**Conclusions** EIT can identify lung areas showing hyperinflation, recruitment or homogeneous fi lling, allowing ventilator settings to be adjusted to optimize pulmonary fi lling characteristics. Monitoring by EIT may thus potentially be used to minimize ventilator-induced lung injury.

model. Sengupta and colleagues concluded that cuff volumes were fairly consistent despite varying tracheal and ETT sizes [1]. Hoffman and colleagues concluded that the volume/pressure relationships in ETT cuffs are linear and that additional air volume above that necessary to reach safe sealing pressure would not result in a precipitous increase in pressure [2].

Methods In a study approved by the Animal Care and Use Committee, excised canine tracheas with four diameters (18, 20, 23 and 26 mm) were intubated with six different 7.5 mm ETTs from different manufacturers (Hi-Lo, TaperGuard and Hi-Lo Intermediate, Tyco Healthcare, Pleasanton, CA, USA; Blue Line SACETT Portex, Smith Medical, Keene, NH, USA; Teleflex ISIS HVT, Research Triangle Park, NC, USA; MicroCuff, Kimberly Clark, Roswell, GA, USA). Cuff pressure was determined with a pressure transducer located at the same level as in pressure [2].

To reach safe sealing pressure would not result in a precipitous increase in pressure [2].

Results The volume/pressure relationship for all cuffs is initially dependent on the resting volume of the cuff. Once the cuff pressure is equal to the force of the tracheal durometer, the cuff pressure increases linearly, reflecting the compliance of the trachea. This occurs at a cuff pressure of 30 cmH2O. In high-volume low-pressure cuffs (Hi-Lo, SACETT, ISIS) the inflation volume was greater compared with low-volume low-pressure cuffs (TaperGuard, Hi-Lo Intermediate). The polyurethane cuff (PU, MicroCuff) exhibited a unique volume/pressure relationship.

Conclusions The tracheal diameter influences the volume necessary to reach a certain cuff pressure with the same-size cuff, contrary to the findings of Sengupta and colleagues [1]. The type of cuff, high-volume versus low-volume oxygen use in adult patients

A Hartopp, K Horner, C Botfield
Princess Royal University Hospital, Orpington, UK

Introduction There are many inaccurate teachings and a paucity of quality evidence about oxygen. We aimed to assess knowledge levels amongst healthcare professionals who administer oxygen with respect to basic physiology, delivery devices and the potential to cause harm in the usual practice is to decrease NIV time, but extending weaning time can lead to higher costs and NIV failure. Pinto showed in 65 COPD patients that a 3-day approach with decreasing time of NIV was feasible. All patients were discharged in 4 days without complications. In our case, a more aggressive approach was attempted. Our results suggest that rapid weaning sequence could be feasible in PE patients, although further studies are needed.

Factors associated with non-invasive ventilation response on the first day of therapy in patients with hypercapnic respiratory failure

G. Gürsel¹, M. Aydoğdu¹, S. Taşyürek¹, G. Gölbaş², S. Nazik¹, A. Demir³

¹Gazi University Medical Faculty, Ankara, Turkey; ²İnönü University Medical Faculty, Pulmonary Diseases Department, Malatya, Turkey; ³Rize University Medical Faculty, Pulmonary Diseases Department, Rize, Turkey

**Introduction**

Non-invasive ventilation (NIV) decreases the need for mechanical ventilation in the early period of acute hypercapnic respiratory failure and factors for success have been studied well. On the other hand, little is known about what kind of factors influence the NIV response in the subacute period. This study aimed to determine the factors influencing PaCO₂ reduction below 50 mmHg in the first 24 hours of therapy.

**Methods**

In this retrospective study we investigated the differences in NIV strategies and patient characteristics between the responsive group (PaCO₂ levels drop below 50 mmHg in first 24 hours) (group 2) and the nonresponsive group (group 1).

**Results**

In 34% of the patients, PaCO₂ reduced to below 50 mmHg in first 24 hours. There were no significant differences between the length of NIV application time and ICU stay, intubations and mortality rates, across the groups. Despite a significantly higher level of pressure support usage in group 1 than in group 2, PaCO₂ did not reduce below 50 mmHg in group 1 within the first 24 hours. While 91% of the responsive group had received nocturnal NIV therapy, only 74% of the nonresponsive group had received NIV therapy all night long (P = 0.036). The home ventilation usage rate was significantly higher in the nonresponsive group than the responsive group.

**Conclusions**

Results of this study showed that, although nocturnal application of NIV in the ICU is associated with a faster drop rate in PaCO₂ levels, the higher pressure support requirement and prior home ventilation usage are predictors for late and poorer response to NIV.

Formal airway assessment prior to emergency tracheal intubation: a regional survey of usual practice

A. Karmali, S. Salah, P. Patel

Imperial College Healthcare NHS Trust, Hammersmith Hospital, London, UK

**Introduction**

Formal airway assessment prior to tracheal intubation is one of the core skills taught to trainees in anaesthesia and forms part of routine perioperative practice. In the United Kingdom, anaesthetists perform 95% of the intubations and mortality rates, across the groups. Despite a significantly higher level of pressure support usage in group 1 than in group 2, PaCO₂ did not reduce below 50 mmHg in group 1 within the first 24 hours. While 91% of the responsive group had received nocturnal NIV therapy, only 74% of the nonresponsive group had received NIV therapy all night long (P = 0.036). The home ventilation usage rate was significantly higher in the nonresponsive group than the responsive group.

**Results**

In 34% of the patients, PaCO₂ reduced to below 50 mmHg in first 24 hours. There were no significant differences between the length of NIV application time and ICU stay, intubations and mortality rates, across the groups. Despite a significantly higher level of pressure support usage in group 1 than in group 2, PaCO₂ did not reduce below 50 mmHg in group 1 within the first 24 hours. While 91% of the responsive group had received nocturnal NIV therapy, only 74% of the nonresponsive group had received NIV therapy all night long (P = 0.036). The home ventilation usage rate was significantly higher in the nonresponsive group than the responsive group.

**Conclusions**

Results of this study showed that, although nocturnal application of NIV in the ICU is associated with a faster drop rate in PaCO₂ levels, the higher pressure support requirement and prior home ventilation usage are predictors for late and poorer response to NIV.

**Conclusion**

Non-invasive ventilation (NIV) decreases the need for mechanical ventilation in the early period of acute hypercapnic respiratory failure and factors for success have been studied well. On the other hand, little is known about what kind of factors influence the NIV response in the subacute period. This study aimed to determine the factors influencing PaCO₂ reduction below 50 mmHg in the first 24 hours of therapy.

**Methods**

In this retrospective study we investigated the differences in NIV strategies and patient characteristics between the responsive group (PaCO₂ levels drop below 50 mmHg in first 24 hours) (group 2) and the nonresponsive group (group 1).

**Results**

In 34% of the patients, PaCO₂ reduced to below 50 mmHg in first 24 hours. There were no significant differences between the length of NIV application time and ICU stay, intubations and mortality rates, across the groups. Despite a significantly higher level of pressure support usage in group 1 than in group 2, PaCO₂ did not reduce below 50 mmHg in group 1 within the first 24 hours. While 91% of the responsive group had received nocturnal NIV therapy, only 74% of the nonresponsive group had received NIV therapy all night long (P = 0.036). The home ventilation usage rate was significantly higher in the nonresponsive group than the responsive group.

**Conclusions**

Results of this study showed that, although nocturnal application of NIV in the ICU is associated with a faster drop rate in PaCO₂ levels, the higher pressure support requirement and prior home ventilation usage are predictors for late and poorer response to NIV.

Urgent orotracheal intubation in critically ill patients

M. Hernández Bernal, JJ Manzanares Gomez, C. Soriano Cuesta, A. Agrifoglio Rotaeba, J. Figueira, J. López, M. Jimenez Lendinez

La Paz University Hospital, Madrid, Spain

**Introduction**

The aim of this study is to analyze the incidence of difficult intubation, and likewise characteristics, complications and mortality of urgent orotracheal intubation (OTI) in critically ill patients.

**Methods**

An observational, descriptive and prospective study. We analyze the impact of difficult OTI, morbidity and mortality in urgent OTI, in the noncoronary ICU of a third-level university hospital in Madrid. We collected all OTIs during the period of 1 year. Demographic data, blood pressure and O₂ saturation with pulseoximetry, before and after OTI, indications, type of technique, medication administered, place where the technique was performed, and complications were collected.

**Results**

Patients: 277. OTIs: 305. Average attempts: 1.15 (SD: 0.41). Sex: male (M): 197 (64.6%), female (F): 108 (35.4%). Age: 56 years (15 to 87). Indications for OTI: low level of consciousness: 103 (34%), excessive work of breathing: 88 (29%), airway protection: 58 (19%), poor secretion management: 44 (14.4%), endotracheal tube change: 29 (9.5%), combative patient: 27 (8.8%), autoextubation: 6 (2.1%), glottis and laryngeal edema: 5 (1.7%), others: 6 (2%). Two or more indications agreed in 36%. Place technique was performed: ICU: 172 (56.4%), Emergency Department (ED): 85 (27.9%), hospital ward: 29 (9.5%), burn unit: 16 (5.2%), others: 3 (1%). Complications: 113 (37%): hemodynamic deterioration: 72 (23.6%), hypoxemia: 22 (7.2%), esophageal intubation: 5 (1.6%), selective bronchial intubation: 4 (1.3%), brachioaspiration: 4 (1.3%), impossible OTI: 3 (0.9%), others: 3 (0.9%). Difficult and impossible OTI: 7 (2.3%); difficult OTI: 4 (1.3%), impossible OTI: 3 (0.98%). Average age: 52 years (38 to 81). Sex: Male (M): 3 (42.8%), Female (F): 4 (57.2%). Place technique was performed: ICU: 3 (42.9%), ED: 2 (28.3%), hospitalization ward: 1 (14.3%), burn unit: 1 (14.3%). Average attempts: 4.5 (SD 0.5). Total mortality of the study: 3 (0.98%).

**Conclusions**

In our study, difficult intubation rates were lower than those reported in other series, so it is remarkable the low mortality of the series, less than 1%, which was determined by hemodynamic deterioration after the technique and not associated with the procedure. In view of the results it is advisable to carry out predictive tests, taking into account the characteristics of the critical patients who require urgent intubation, to provide technical difficulties in carrying out the process and anticipate the preparation of necessary materials before starting sequence intubation; likewise, new systems have access to the airway for risk.

Propofol is the induction agent of choice for urgent intubations with UK physicians

KD Rooney, R. Jackson, A. Binks, A. Jacques, RT IC-Severn

Bristol School of Anaesthesia, Bristol, UK

**Introduction**

We performed a multicentre, prospective, observational study across nine hospitals in the Severn Deanery (UK). Choice of
induction agents for out-of-theatre intubations was compared against historical controls.

Methods Data were collected prospectively on all out-of-theatre tracheal intubations occurring within the region during a 1-month period. We included all intubations performed outside areas normally used for elective or emergency surgery. Neonates and cardiac arrests were excluded from analysis. Data were collected locally using a standardised proforma and centrally collated. All intubations were performed according to the preference of the treating team. Results Hypnotics were used for 14% of out-of-theatre intubations. Seventy-six per cent of intubations were accomplished by the use of propofol. Propofol was more likely to cause hypotension than other hypnotics (27.4% vs. 14.3%). Use of alternatives increased with seniority of the intubator. Consultants and senior trainees were less likely to use propofol than junior trainees (73% vs. 93%). Etomidate was not used at all. Previous studies from North American and European centres demonstrate greater use of alternative induction agents, particularly etomidate and ketamine [1-4]. UK practice has also changed over time, comparing our study with historical controls [5,6].

Conclusions There is significant geographical variation in choice of induction agent for critically ill patients. There has been an increase in the use of propofol amongst UK physicians over the past 7 years. Choice (23%) of patient has a significant impact on physiological stability and out-of-theatre intubations are commonly performed in emergent circumstances on unstable patients. This study raises concerns that UK physicians choose induction agents based on familiarity rather than the pharmacodynamic profile.

P154 Frequency and significance of post-intubation hypotension during emergency airway management
A Heffner, D Swords, J Kline, A Jones
Carolina's Medical Center, Charlotte, NC, USA

Introduction Arterial hypotension is known to follow emergency intubation but the significance of this event is poorly described. We aimed to measure the incidence of post-intubation hypotension (PIH) following emergency intubation and determine its association with hospital mortality.

Methods A retrospective cohort study of endotracheal intubations performed in a large, urban emergency department over a 1-year period. Patients were included if they were >17 years old and had systolic blood pressure (SBP) >90 mmHg for 30 consecutive minutes prior to intubation. Patients were analyzed in two groups: those with PIH defined by SBP <90 mmHg within 60 minutes of intubation, and those with no PIH. The primary outcome was hospital mortality.

Results Emergency intubation was performed on 465 patients, of which 336 met inclusion criteria and were analyzed. The median patient age was 49 years, 59% of patients presented with nontraumatic illness and 92% underwent induction with etomidate. PIH occurred in 76/336 (23%) of patients. The median time to first PIH was 11 minutes (IQR 2 to 27). Intubation for acute respiratory failure was the only independent predictor of PIH (OR = 2.1, 95% CI = 1.1 to 4.0). Patients with PIH had significantly higher in-hospital mortality (33% vs. 21%; 95% CI for 12% difference = 1 to 23) and longer mean ICU length of stay (9.7 vs. 5.9 days, P <0.01) and hospital length of stay (17.0 vs. 11.4 days, P <0.01). Multivariate logistic regression analysis confirmed PIH as an independent predictor of hospital mortality (OR = 1.9, 95% CI = 1.1 to 3.6).

Conclusions PIH occurs in nearly one-quarter of normotensive patients undergoing emergency intubation. Intubation for acute respiratory failure is an independent predictor of PIH. PIH is associated with a significantly higher in-hospital mortality and longer ICU and hospital lengths of stay.

P155 Clinical experiences with a new endobronchial blocking device: the EZ-Blocker
T Végh, A Enyedi, I Takács, J Kollár, B Fülesdi
University of Debrecen, Hungary

Introduction Both elective and emergency thoracic surgical procedures may require one-lung ventilation (OLV) for lung isolation [1]. Although in the majority of the cases a double lumen endotracheal tube (DLT) is the first choice, there are situations when insertion of DLT is not feasible [2]. We therefore intended to test the applicability of a recently developed endobronchial blocker (BB), the EZ-Blocker, in clinical practice.

Methods Data were obtained from 10 patients undergoing thoracic surgery necessitating OLV. For lung isolation, a single lumen tube (SLT) and EZ-Blocker as BB were used. The time of insertion and positioning of BB, the lung deflation time with the BB cuff inflated and deflated, the minimal occlusion volume (MOV) of the BB cuff with 25 cmH₂O positive airway pressure (PAP) and intracuff pressure (ICP) at MOV were registered. Based on the CT scan the diameter of the right (RMB) and left main bronchus (LMB) at 1 cm distal apart from the bifurcation was measured (MOV was defined as 5.5 cm distance of the upper lobe from the rib cage at open chest).

Results The insertion time was 76 ± 15 seconds. The lung deflation time through the lumen with the BB cuff inflated was 700 ± 83 seconds, and with a deflated cuff through the lumen of SLT was 9.4 ± 0.7 seconds. The MOV was 6.7 ± 1 ml in LMB versus 8 ± 1 ml in RMB (P = 0.03). The ICP was 40 ± 4 mmHg in LMB versus 85 ± 5 mmHg in RMB (P <0.001). With linear regression there were strong positive relationships between the diameter of MB and MOV/ICP.

Conclusions The use of EZ-Blocker is easy and safe for infrequent users, too. The short insertion time and short lung deflation time allows use in an emergency situation or in case of a difficult airflow. Only a small fraction of ICP (10 to 20%) is transmitted to the bronchial wall and it does not cause mucosal ischemia. The diameter of the MB has great impact on the MOV and ICP. The MOV is similar but ICP is smaller than published in previous reports with other BBs [3].

P156 Rohrer's constant, k₂, as a factor for determining endotracheal tube obstruction
AG Fliavri, N Maniatis, E Dimitriadou, M Theodorakopoulou, E Paramythiotou, N Christoforidis, A Kaziani, D Koukios, F Drakopanagiotakis, A Armaganidis
Attikon University Hospital, Athens, Greece

Introduction The purpose of the study was to apply a method by which to measure Rohrer’s constant, k₂, in order to estimate endotracheal tube (ETT) resistance (RETT). The resistance drop across the ETT is expressed by the equation RETT = k₁ + k₂ V', as Rohrer described, where k₂ is the constant of laminar flow (V') and k₁ is the constant of turbulent flow. In our past study we graphed RETT over inspiratory V' for ETTs with inner diameters of 6.5 to 9.0 mm [1]. This graph provided us with k₁ and k₂ constant values, for each ETT size.

Methods Ten intubated patients with ETTs with difficulty in patency were included in the study. Patients were all fully sedated and mechanically ventilated, by a Siemens Servo 300 ventilator, under constant flow. Pressure data were obtained: at the proximal end of the ETT (Ppeak), reflecting the impedance distally to the proximal end of the ETT; and at the distal end of the ETT (Pdist), reflecting the resistance distally to the distal end of the ETT. Pdist was recorded by an intratracheal catheter, placed 2 cm above the carinal end of the ETT. Each resistance was calculated by dividing ΔP (Ppeak – Pdist) by V'; at every point of interest (either proximal or distal sites), using the rapid end-inspiratory occlusion method. RETT resulted from the difference:
Conclusions

INTRODUCTION

The purpose of the study was to record the incidence, etiology, and management of acute desaturation (AD) in intubated critically ill ICU patients.

METHODS

We collected demographics of the patients developing AD as a documented fall in SaO2 (>3%) in combination with clinical signs of respiratory distress requiring medical intervention. Etiology of AD was investigated by clinical evaluation, ABG analysis and chest X-ray. Numerical data are presented as mean (SEM) or median.

RESULTS

We included 57 patients (37 men) admitted to our ICU within 6 months of mean age 54.4 (2.7) and mean ICU stay of 25.9 (5.7) days. We recorded 42 episodes of AD in 19 patients (33%). Mean age was 51.4 (3.8), mean ICU stay 51.1 (15.3) days and illness severity APACHE II 20.8 (1.6), SAPS II 52.2 (3.3) and SOFA 9.2 (0.8). The incidence was one episode per 30 ventilator-days or one every 4.3 days, corresponding to 2.3 (1.1) episodes per patient. Mean fall in SaO2 was 5%, in PaO2 44 mmHg and in PaO2/FiO2 113. Eight episodes developed while on T-piece due to atelectasis/secreetion retention (6) or respiratory muscle fatigue (2). The remaining episodes developed in patients under sedation: atelectasis/secreetion retention (10), pulmonary edema (6), fever/SIRS (5), occlusion/displacement of endotracheal tube (5), patient–ventilator asynchrony (4), bronchospasm (2), patient transfer (1) and pneumothorax (1). Management included FiO2 increase (53.5%), physiotherapy/bronchial toilet/patient poisoning (39.5%), change in ventilator mode (23.3%), PEEP increase (23.3%), drugs (sedation, diuretics, bronchodilators, 16.2%), change in respiratory rate (11.6%), use of Ambu bag (4.6%), reintubation (2.3%), insertion of chest tube (2.3%) and other measures (11.6%). Most patients required at least two interventions. Patients developing AD had significantly higher (P < 0.05) SAPS II (median 54 vs. 42), SOFA (9 vs. 6) scores and ICU stay (41 vs. 8). None of the episodes had fatal outcome. Most common hours for developing AD were 07.00, 14.00 and 23.00.

CONCLUSIONS

AD is a common medical emergency condition requiring prompt interventions. One over three patients developed at least two episodes of AD corresponding to one episode per 4.3 days. The most common etiology is atelectasis and secretion retention.

P158

Continuous control of tracheal cuff pressure and microaspiration of gastric contents: a randomized controlled study

S Nseir, F Zerimech, C Fournier, R Lubret, P Ramon, A Durocher, M Baldyuck

University Hospital, Lille, France

INTRODUCTION

Underinflation of a tracheal cuff frequently occurs in critically ill patients, and results in microaspiration of contaminated oropharyngeal secretions and gastric contents that plays a major role in the pathogenesis of VAP. The aim of this study was to determine the impact of continuous control of cuff pressure (P cuff) on microaspiration of gastric contents.

METHODS

Patients requiring mechanical ventilation through a PVC-cuffed tracheal tube >48 hours were eligible. Patients were randomly allocated to control of P cuff using a pneumatic device (Nosten®) (intervention group, n = 61) or routine care of P cuff (control group, n = 61). Target P cuff = 25 cmH2O in the two groups. The primary outcome was microaspiration of gastric contents as defined by the presence of pepesin at a significant level (>200 ng/ml) in tracheal secretions. Secondary outcomes included incidence of microbiologically confirmed VAP (tracheal aspirate >105 cfu/ml), incidence of tracheobronchial colonization, and tracheal ischemic lesions as defined by a macroscopic score. Pepsin was quantitatively measured in all tracheal aspirates during the 48 hours following randomization. A patient was considered as having abundant microaspiration when >65% of tracheal aspirates were pepesin positive. Patients remained in a semirecumbent position in bed, and a written enteral nutrition protocol was used. All analyses were performed on an intention-to-treat basis.

RESULTS

Patient characteristics were similar in the two groups. The pneumatic device was efficient in controlling P cuff. Pepsin was measured in 1,205 tracheal aspirates. The percentage of patients with abundant microaspiration (18% vs. 46%, P = 0.002, OR (95% CI) 0.25 (0.11 to 0.59)), pepesin level (median (IQR) 195 (95 to 250) vs. 251 (130 to 390), P = 0.043), and VAP rate (9.8% vs. 26.2%, P = 0.032, 0.30 (0.11 to 0.84)) were significantly lower in the intervention group compared with control group. However, no significant difference was found in rate of patients with tracheobronchial colonization (34% vs. 39%, P = 0.7) or in tracheal ischemia score (4.5 (1 to 6) vs. 4.3 (1 to 7), P = 0.9) between the two groups.

CONCLUSIONS

Continuous control of P cuff is associated with significantly decreased microaspiration of gastric contents in critically ill patients.
for those patients undergoing tracheostomy <4 days into critical care admission (early group) and >4 days into critical care admission (late group). Continuous data when expressed as mean (SD) were analysed using t-test and when expressed as median (IQR) were analysed using the Mann–Whitney U test. Binary outcome data were analysed using the chi-square test. P < 0.05 was considered statistically significant.

**Results**

The early group (n = 32) had a mean LOS of 19 days (SD = 16.57), median weaning interval of 9 days (IQR = 9.5) and a mortality of 12.5% (n = 4). The late group (n = 43) had a mean LOS of 21.6 days (SD = 12.62), median weaning interval of 6 days (IQR = 13) and a mortality of 27.9% (n = 12). More tracheostomies were performed late at our institution, but despite this there was no significant difference in LOS (P = 0.481, t test), weaning interval (P = 0.852, Mann–Whitney U test) or 28-day mortality (P = 0.107, chi-square test) between the two groups.

**Conclusions**

Many clinicians believe that early tracheostomy insertion may benefit critically ill patients requiring mechanical ventilation. This benefit does not seem to extend to 28-day survival, critical care LOS or weaning from mechanical ventilation.

**Duration of mechanical ventilation on the result of diaphragmatic function in weaning**

HB Qiu, W Guo, Y Yang

Zhongda Hospital, Southeast University, Nanjing, China

**Introduction** To investigate the influence of duration of mechanical ventilation on the diaphragmatic function.

**Methods**

Patients included in this study were those mechanically ventilated for at least 24 hours and were preparing to wean from December 2006 to December 2009 in the ICU of Nanjing Zhong-Da Hospital. Patients, according to the duration of mechanical ventilation, were divided into group A (ventilated less than 3 days) and group B (ventilated more than 3 days). A 30-minute spontaneous breathing test (SBT) was carried out on the patients satisfying the weaning permission. Indices of diaphragm function such as electrical activity of diaphragm (Edi), neuromuscular strength index (NMS), neuromechanical coupling (NMC) and neuroventilatory coupling (NVC) at 0, 5 and 30 minutes of SBT were monitored.

**Results**

Forty-four patients were included finally, of whom 19 patients (43.2%) were ventilated more than 3 days (group B), while the average duration of mechanical ventilation was 6.2 ± 3.9 days. Twenty-five patients were ventilated less than 3 days (group A), whom had an average duration of mechanical ventilation for 2.2 ± 0.7 days. There was no significant difference in Edi, NMS, NMC or NVC at 0 minutes of SBT between the two groups. Edi and NMS in group B were 20 ± 11 μV and 571 ± 338 μV·cpm at 5 minutes of SBT, which were both largely more than group A (16 ± 8 μV and 387 ± 208 μV·cpm, P <0.05). Then, NMC and NVC had no significant difference. At SBT 30 minutes, Edi and NMS in group B appeared to be significantly higher than those in group A (23 ± 11 μV vs. 15 ± 8 μV, 598 ± 309 μV·cpm vs. 362 ± 224 μV·cpm, P <0.05). Whereas NVC in group B (20 ± 12 ml/μV) was lower than group A (35 ± 21 ml/μV, P <0.05).

**Conclusions**

The contractility and endurance of diaphragm decreased in patients whom were ventilated more than 3 days at 30 minutes of SBT. It seemed that an increment duration of mechanical ventilation could exacerbate diaphragm dysfunction, which might be one of the important factors leading to failed weaning.

**Hand-grip test is a good predictor of extubation success in adult ICU patients**

D De Bels1, J Devriendt1, P Gottignies1, D Chochrad2, S Theunissen3, T Snoeck1, C Balestra3, U Pilard3, S Roques1

1 Brugmann University Hospital, Brussels, Belgium; 2Hôpitaux IRRIS Sud, Brussels, Belgium; 3ISEK Environmental Physiology Laboratory, Brussels, Belgium

**Introduction** Ventilator weaning protocols have been published during the past 20 years. Although patients fulfill weaning criteria, they may still experience extubation failure. Risk factors include respiratory muscle weakness. This is accompanied by peripheral muscle weakness. The aim of the study is to evaluate the possible relation between peripheral (hand) muscle strength and extubation success in ICU patients.

**Methods**

Fifty-four consecutive patients (62 ± 14 years) extubated in the ICUs of the Brugmann University Hospital and the Etterbeek-Ixelles General Hospital were included in the study. Extubation failure was defined as reintubation within 48 hours after extubation. Hand muscle strength is measured by a grip test method.

**Results**

Maximal hand grip strength is statistically (14.8 ± 7.7 vs. 5.3 ± 3.8 kg, P <0.001) higher in patients successfully undergoing extubation compared with patients failing extubation, See Figure 1.

**Conclusions**

Hand grip strength testing is a good predictor of successful extubation in ICU patients. The positive predictive value of 100% is obtained if maximal strength is >13 kg. Further studies are needed before grip testing could be routinely used as a decision-making test for extubation in ICU patients.

**Use of NT-proBNP in weaning from mechanical ventilation**

A Martini, B Benedetti, N Menestrina, E Polati, E Bresadola, L Gotti

University Hospital, Verona, Italy

**Introduction** Our objective is to evaluate the role of the levels of B-type natriuretic peptide (BNP), released in response to increased wall tension, as a predictor of weaning failure.

**Methods**

We enrolled 98 patients, admitted to the ICU for acute respiratory failure, who underwent mechanical ventilation and were considered ready for a weaning trial. Patients were divided by means of echocardiographic criteria into four groups according to the severity of heart dysfunction: Group 1: normal left and right ventricular function and absence of relevant valvulopathy; Group 2: mild left systolic ventricular dysfunction, ejection fraction >40%; mild valvulopathy, diastolic dysfunction >II; Group 3: moderate to severe left systolic ventricular dysfunction, ejection fraction <40%; and Group 4: severe right ventricular dysfunction: ventricular volumes R/L >0.6, arterial pulmonary pressure >30 mmHg. Plasma NT-proBNP was measured just before (BNP 1) and at the end (BNP 2) of the weaning trial in all patients. Patients who passed the weaning test were finally extubated.

Extubation was considered failed if the patient required reintubation within 48 hours. We compared plasma BNP concentrations in the different groups with Mann–Whitney or chi-square tests and we considered also ΔBNP (BNP 2 – BNP 1) and %Variation (Δ / BNP 1).

**Results**

In the whole sample NT-proBNP levels were not significantly different in patients who had a positive weaning and in those who failed it. ΔBNP and %Variation were higher (P <0.001) in patients who failed the test than in patients who passed the test. In Group 1
a higher ΔBNP, and in Group 2 a higher ΔBNP and %Variation, were correlated with weaning failure. In Group 4, instead, the plasma BNP concentration decreased during the weaning test. ROC curve analysis was performed to assess ΔBNP and %Variation’s ability to discriminate between patients who had a positive weaning and those who failed. In Group 1 the area under the ROC curve values were 0.88 for ΔBNP and 0.94 for %Variation. In Group 2 the area under the ROC curve values were 0.64 for ΔBNP and 0.86 for %Variation.

Conclusions Recent papers evaluated the role of BNP in patients who had undergone mechanical ventilation. In our population ΔBNP and %Variation before and after the weaning test are more reliable than NT-proBNP levels to detect extubation failure in patients with mild cardiopathy or without relevant cardiopathy. In patients with severe cardiopathy because of the complexity of clinical pattern, NT-pro-BNP cannot be used as a predictive marker of extubation failure.

Efficacy of implementation strategies of an evidenced-based awakening and breathing protocol
O Almuslim, M Rezk, N Hassan
King Fahad Specialist Hospital – Dammam, Saudi Arabia

Introduction A protocol that paired spontaneous awakening trials (SAT) and spontaneous breathing trials (SBT) decreased duration of mechanical ventilation (DMV), ICU length of stay (LOS) and mortality [1]. We studied the efficacy of multifaceted implementation strategies (MIS) of an evidenced-based protocol at a tertiary academic center.

Methods This was a prospective observational cohort study with historical control. The cohort consisted of consecutive patients who were extubated at least once during the ICU stay. The intervention was MIS of a quality improvement (QI) protocol pairing SAT and SBT. These strategies included: preprinted daily order sheets, structured daily multidisciplinary rounds, QI monitoring and regular feedback to the ICU staff. The outcomes: DMV, ICU LOS, reintubation and hospital mortality. Chi-square and t tests, adjusted logistic and Cox regressions were used.

</table>

Results Total patients n = 120 (2009, n = 40; 2010, n = 80). The baseline characteristics were imbalance for age and APACHE II. The 2010 group (after QI) had less DMV, ICU LOS and hospital mortality (Table 1). The adjusted hazard ratio in reducing time to extubation = 0.57 (95% CI = 0.37 to 0.88) and adjusted odds ratio for hospital mortality = 0.27 (95% CI = 0.12 to 0.67) in the 2010 group. See Figure 1.

Conclusions MIS of a paired SAT and SBT protocol reduced duration of MV, ICU LOS and hospital mortality.

Can we predict left ventricular dysfunction-induced weaning failure? Invasive and echocardiographic evaluation
A Abdelbary, W Ayoub, Y Nassar, K Hussein
Faculty of Medicine, Cairo University, Cairo, Egypt

Introduction The aim was to study the relation of weaning failure to development of diastolic dysfunction using echocardiography and PA catheter.

Methods Thirty invasively mechanically ventilated patients fulfilling criteria of weaning from mechanical ventilation were shifted to SBT (using low PSV (8 cmH2O)) for 30 minutes. Two sets of variables were measured at the beginning and end of the SBT. Weaning failure was defined as: failed SBT, reintubation and/or ventilation or death within 48 hours following extubation. A Swan–Ganz catheter was used to obtain the right atrial (RAP), pulmonary artery (PA), pulmonary artery occlusion (PAOP) pressures, and cardiac index (CI). Echocardiography: the LV internal diameter at end diastole (LVIDd) and end systole (LVIDs), ejection fraction (LVEF), E/A ratio, deceleration time (DT) (ms), isovolumetric relaxation time (IVRT), and E/A ratio.

Results Mean age was 56.6 ± 15.9 years, 53% were males. The outcome of weaning was successful in 76.6% of patients. The patients were subdivided into two groups according to weaning outcome: Group I, 23 patients (successful weaning); Group II, seven patients (failed weaning). RAP, PAOP and SVO2 were similar at the start of SBT (6.3 ± 1.9 vs. 7.6 ± 2.3, P = 0.1; 12 ± 3.7 vs. 14.6 ± 3, P = 0.4; 72.2 ± 24 vs. 71 ± 3.1, P = 0.1) between Groups I and II yet significantly different at the end (6.2 ± 2.4 vs.10.3 ± 3.5, P = 0.01; 12.8 ± 3.5 vs.19 ± 5.4, P = 0.004; 73 ± 2.8 vs. 66.6 ± 7, P = 0.009), respectively. CI was similar between Groups I and II at both ends of the SBT, P = 0.5 and P = 0.9. Groups I and II had similar LVdIs and EF at the beginning of SBT (3 ± 0.7 vs. 3.3 ± 0.5, P = 0.2; 68 ± 8 vs. 62 ± 6, P = 0.08) yet different at the end (3.5 ± 0.6 vs. 3.5 ± 0.5, P = 0.046; 66 ± 8 vs. 58 ± 7, P = 0.03), respectively. There was no significant differences in E/A, IVRT, DT yet a significant difference in CI between Group I and Group II at both ends of the trial (1.04 ± 0.4 vs. 0.97 ± 0.3, P = 0.78; 1.02 ± 0.4 vs. 1.07 ± 0.4, P = 0.78; 94 ± 26 vs. 99.6 ± 18, P = 0.02; 97 ± 22 vs. 91 ± 24, P = 0.57; 194 ± 31 vs. 196 ± 30, P = 0.98; 197 ± 27 vs. 189 ± 33, P = 0.6; 8.9 ± 2 vs. 12.2 ± 4, P = 0.02; 9.4 ± 2.3 vs. 13 ± 5, P = 0.02), respectively.

Conclusions LV dysfunction may have an impact on weaning outcome. Invasive monitoring as well as echocardiography and tissue Doppler indices may be reliable in monitoring and detection of LV dysfunction, and subsequently may be possibly useful in improving weaning outcome. RAP may be a particularly reliable and easy method to monitor during the period of weaning.

High-flow oxygen therapy through nasal cannulae versus low-flow oxygen therapy via Venturi mask after extubation in adult, critically ill patients
F Antonicelli, A Cataldo, R Festa, F Iodone, A Moccaldo, M Antonelli, SM Maggiore
‘A. Gemelli’ University Hospital, Rome, Italy

Introduction Oxygen therapy, usually delivered with the Venturi mask, is frequently used in critically ill patients after extubation. This device delivers low-flow oxygen with cold humidification. Recently available is
a new device for oxygen therapy through nasal cannulae (NHF). Such a device delivers up to 60 l/minute oxygen, with heated humidification. The aim of this study was to compare the effects of these two devices for oxygen therapy on arterial blood gases, discomfort and adverse events in critically ill patients after extubation.

**Methods** Inclusion criteria were mechanical ventilation for more than 24 hours and a successful spontaneous breathing trial with PaO2/ FiO2 < 300 at the end of the trial. Exclusion criteria were tracheostomy, age < 18 and anticipated need for non-invasive ventilation after extubation. Patients were randomized to receive oxygen therapy with NHF or Venturi mask after extubation. With both devices, nominal FiO2 was set to obtain SpO2 between 92 and 98% (between 88 and 95% in hypercapnic patients). Arterial blood gas, respiratory rate, and discomfort were recorded at 1, 3, 6, 12, 24, 36, and 48 hours from inclusion. Discomfort was assessed by asking patients to rate their discomfort related to the interface and to the upper airway dryness (mouth, throat, and nose dryness, difficulty to swallow and throat pain), using a numerical scale from 0 (no discomfort) to 10 (maximum discomfort).

**Results** Seventy-five patients were enrolled (40 NHF, 35 Venturi mask). No difference was observed in the baseline characteristics at inclusion. P02/FiO2 was higher in the NHF group, being statistically significant (1.3 ± 1.1 of 2.0 ± 0.7, P < 0.01). PaCO2 was similar in the two groups. Nominal FiO2 and the respiratory rate were always lower with NHF than with Venturi mask (30 ± 6 vs. 37 ± 10%, P = 0.01, and 21 ± 4 vs. 27 ± 4 breaths/minute at 24 hours, P < 0.01, respectively). Discomfort due to the interface was higher with the Venturi mask at 12, 24, 36, and 48 hours (4 ± 3 ± 6 ± 3 at 24 hours, P < 0.01). Discomfort related to dryness of the upper airways was also higher with the Venturi mask than with NHF at all time steps (2 ± 2 vs. 4 ± 2 at 24 hours, P < 0.01). Oxygen desaturations and interface displacements were more frequent with the Venturi mask than with NHF (94 vs. 40% patients, P < 0.01, and 71 vs. 30% patients, P < 0.01, respectively).

**Conclusions** NHF is an effective method for delivering oxygen therapy after extubation, allowing better oxygenation with less patient discomfort and adverse events than the Venturi mask.

**P166** Post-intubation tracheal stenosis in the ICU: diagnosis and treatment

N Makholu1, E Altman1, S Croitoru1, S Ivy1, A Gurevich1, S Krimerman1, M Croitoru2

1Western Galilee Hospital, Naharya, Israel; 2Western Galilee Hospital Naharia, Israel; 3Bnai Zion Medical Center, Haifa, Israel

**Introduction** Prolonged mechanical ventilation of critically ill patients may be complicated by formation of post-intubation tracheal stenosis (PITS) with respiratory disorders of different grades. Critical post-intubation tracheal stenosis (CPISTs) may create life-threatening conditions. However, organized teamwork on the ground in the ICU may give positive results.

**Methods** We reviewed retrospectively the medical records of 17 patients admitted to our ICU with PITS and CPISTs during 2003 to 2010. Ten of them were males with mean age 68 years old and seven females with mean age 72. In relatively stable patients, computed tomography (CT) and virtual tracheoscopy (VT) were used, followed by rigid (RB) or fiberoptic (FOB) bronchoscopy. In emergency cases we used RB for diagnosis and treatment. All procedures in the operating room were done under general anesthesia, the majority with high-frequency jet ventilation (HFJV).

**Results** In 13 patients PITS had diameter of about 5 to 6 mm and produced dyspnea. Four of 13 patients had soft PITS that were dilated with boogie; in another five patients with hard stenosis, balloon dilation was used. In the remaining four patients with severe respiratory distress, CPIST was diagnosed as having diameter of 3 to 4 mm. Emergency tracheostomy was performed in two patients; excision of large granulations in one case, and intubation with small endotracheal tube after partial dilation in one case.

**Conclusions** Management of PITS in the ICU was beneficial for some of our patients and especially those with CPISTs. VT allowed precise measurements of PITS; HFJV created stable conditions for work.

Decannulation: in the ICU or in the ward? Does it really matter?
O Milercy, J Lopez, J Piguena, J Manzanares, M Hernandez
La Paz Hospital, Madrid, Spain

Introduction The aim of our study was to evaluate the in-hospital mortality of patients who underwent tracheostomy during their ICU admission, and were discharged to different areas of the hospital prior to decannulation.

Methods A prospective observational study of a group of patients who underwent tracheostomy in our ICU from January 2001 to December 2007 and were discharged to different areas of the hospital prior to decannulation. The mortality of patients decannulated or not in the wards was reviewed.

Results Between January 2001 and December 2007, 6,333 patients were admitted to our unit. A total of 1,528 needed mechanical ventilation (MV) for more than 48 hours. Four hundred and forty-three patients were admitted to our unit. A total of 1,528 needed mechanical ventilation (MV) for more than 48 hours. Four hundred and forty-three patients were discharged to different wards. Of these 351, 161 (45.8%) could be decannulated in the ICU and 109 (31%) in the wards. Eighty-one patients (23%) could not be decannulated. The ward mortality in patients decannulated in the ICU was 5.6% (9/161), for those decannulated in the wards was 10% (11/109). In patients not decannulated the mortality reached 37% (30/81). There were no differences of statistical significance in mortality between patients decannulated in the ICU and patients decannulated in the wards (5.6% vs. 10%; OR = 1.9 CI = 0.8 to 4.2). The main diagnoses in the patients who died on the wards were: 31 residual encephalopathy (post-anoxic, post-traumatic, others), five severe chronic respiratory failure, three spinal cord injury, two neuromuscular diseases.

Conclusions Mortality was not related to whether decannulation was done in the ICU or on the ward. Although mortality was higher in the group of patients that could not be decannulated in either setting due to their poor neurological or functional status. Several authors suggest tracheostomy in these patients only delays their death without improving overall in-hospital survival due to their poor vital prognosis.

Assessment of the impact of unplanned extubation on ICU patient outcome
Hospital Santa Luzia, Brasilia, Brazil

Introduction The objective of this study is to investigate and analyze the events of unplanned extubation (UE) in the ICU of Santa Luzia Hospital, Brasilia, Brazil. Incidence rates of unplanned extubation vary; reported rates range from 3% to 14%. This phenomenon occurs during procedures performed by healthcare workers, or in self-extubation if the patient removes the endotracheal tube. Unplanned extubations are considered an indicator of healthcare quality in the ICU. Reintubation may be temporary and is associated with complications, including emergency cricothyrotomy, cardiac arrest, and death.

Methods A retrospective cohort study, analysing the cases of UE reported between January 2009 and June 2010 in Santa Luzia Hospital’s ICU. In this period 3,302 patients were admitted, and 551 were submitted to mechanical ventilation (MV). The cases of UE are notified through proper form by the physiotherapy. The incidence rate of unplanned is calculated by the relationship between the number of patients extubated accidentally and the number of patients intubated/day, multiplied by 100.

Results The incidence rate of UE was 0.21% (nine patients in 4,232 days of MV). Only two extubations (22.22%) occurred accidentally while seven cases (77.78%) were self-extubation. Patients were predominantly female (55.56%; n = 5), mean age was 59.86 ± 27.28 years, mean SAPS II score of 35.33 ± 12.50 (RISK: 21.56 ± 18.32%), mean APACHE II score of 10.44 ± 6.27 (RISK: 17.11 ± 15.35%), mean duration of MV ≤ 9.81 days, mean length of stay in ICU 15.89 ± 8.75 days. Two patients (22.22%) needed reintubation. In only one patient (11.11%) urgent cricothyrotomy was required due to difficulty on reintubation. Most patients had already started the weaning process (77.78%). The leading cause of accidental extubation was failure of restraint (88.89%) associated with psychomotor agitation (55.56%). We had three (33.33%) cases of death in the group, but not associated with the UE. The Extracorporeal Life Support Organization: Registry Report, International Summary, January 2009.

Outcome and complications in infants with respiratory failure: venovenous two-site versus double-lumen ECMO
M Hermon, G Mostafa, J Golej, J Figueira, J Manzanares, M Hernandez
Medical University of Vienna, Austria

Introduction Extracorporeal membrane oxygenation (ECMO) provides temporary life support for children with severe respiratory or cardiac failure. Since 1990, more than 27,000 children have received ECMO and an overall survival rate of 76% [1] has been observed. The objective of this study was to compare outcomes and complications of the two-site venovenous versus the double-lumen ECMO in infants with respiratory failure.

Methods The Extracorporeal Life Support Organization (ELSO, Ann Arbor, MI, USA) registry database collected between 1999 and 2009 was provided for research. A total of 9,086 children ≤7 kg BW were treated with ECMO. From these children, those who were older than 32 days and received VV ECMO were excluded for analysis. A total of 270 children met the inclusion criteria. Two hundred and thirty-six children were treated with VVDL ECMO and 34 children received VV two-site ECMO. ELSO registry records were reviewed for the following information: demographic data, type of ventilation, ventilator days and settings during an ECMO run, complications during an ECMO run and outcome.

Results In this study 87% (n = 236) of the children were cannulated with VVDL and 13% (n = 34) using the VV two-site technique. APGAR scores were significantly lower in the VV two-site group. Twenty-four hours after ECMO onset, ventilator settings were significantly higher in the VV two-site group. ECMO duration was significantly shorter in the VV two-site group (137 hours vs. 203 hours, P < 0.001). The total complication rate, however, did not differ between the groups. Survival rates (71% in the VVDL group and 56% in the VV group) were not significantly different either.

Conclusions The total complication rate was found to be similar in both groups. The ECMO duration period was significantly shorter in the VV two-site group. No difference was found in survival rates between the two groups. Neither of the two-cannulation methods – venovenous two-site or venovenous double-lumen ECMO – has shown any significant superiority. The decision about which technique to use for infants depends mainly on the best practice experience of each individual ECMO centre and their routinely-used technical equipment.

Weaning-induced alterations in cardiac function: invasive and echocardiographic assessment
A Abdelbary, W Ayoub, Y Nassar, K Hussein
Faculty of Medicine, Cairo University, Cairo, Egypt

Introduction The aim was to study LV dysfunction during weaning from mechanical ventilation (MV).

Methods Thirty invasively MV patients fulfilling the criteria of weaning were shifted to SBT (using low PSV (8 cmH2O)) for 30 minutes. Two sets of variables were measured at the beginning and end of the SBT: respiratory rate (F), tidal volume (VT), minute ventilation (VE), peak inspiratory pressure (PIP), PaO2/FIO2 ratio (P/F ratio); and one reading at the start of the SBT of: airway resistance (Raw), static respiratory compliance (Cst), maximum negative inspiratory pressure (NIP), (F/VT), arterial blood gases. Weaning failure was defined as: failed SBT, reintubation and/or reventilation or death within 48 hours. Swan–Ganz catheterization was used to obtain the right atrial (RAP), pulmonary artery (PAP), pulmonary artery occlusion (PAOP) pressures, and cardiac index (CI). Echocardiography was used to obtain the LV internal diameter at end diastole (LVIDd) and end systole (LVIDs), ejection fraction (LVEF), the ratio of the deceleration time (DT) (ms), isovolumetric relaxation time (IVRT), Doppler tissue imaging (DTI) and E/E’.

Results Mean age 56.6 ± 15.9 years, 53% were male. Weaning was successful in 76.6% of patients. There was reduction in VT with increase in F and VE (0.53 ± 0.06 vs. 0.45 ± 0.1, P = 0.0003; 12.5 ± 20 vs. 20.3 ± 7.5, P < 0.0001; 6.6 ± 1.5 vs. 8.8 ± 2.4, P < 0.0001, respectively). P/F_1 was higher than P/F_2 (278 ± 86 vs. 252 ± 74, P < 0.0001; 6.6 ± 1.5 vs. 8.8 ± 2.4 l, P < 0.0001, respectively). There was no difference in Hb, Hct and PAOP at the beginning of SBT, there was significant correlation E/E’ = 0.8; 194.6 ± 30 vs. 195 ± 28 ms, P < 0.01; 3.2 ± 0.6 vs. 3.2 ± 0.5, P = 0.4, respectively. There was a reduction in LVEF, the ratio of the deceleration time (DT) (ms), isovolumetric relaxation time (IVRT), Doppler tissue imaging (DTI) and E/E’. Baseline PaO2, PaCO2, and Hct were similar. There was a reduction in PaO2 (126 ± 32 vs. 115 ± 29, P < 0.0001; 278 ± 86 vs. 252 ± 74, P < 0.0001; 6.6 ± 1.5 vs. 8.8 ± 2.4 l, P < 0.0001, respectively). There was no difference between E/A, IVRT, and PAOP at the beginning of SBT, there was significant correlation between them at the end of SBT (r = 0.6, P = 0.001).

Conclusions LV dysfunction during weaning is mainly diastolic. Changes in E/E’ and RAP and/or PAOP may be the most convenient methods for monitoring diastolic function during weaning from MV.

P172
Impact of open lung ventilation on right ventricular outflow impedance assessed by transoesophageal echocardiography
S Salah, H El-Akabawy
Cairo University, Cairo, Egypt

Introduction Open lung concept ventilation is a method of ventilation intended to maintain end-expiratory lung volume by increased airway pressure [1]. Since this could increase right ventricular (RV) afterload, we investigated the effect of this method on RV outflow impedance during inspiration and expiration using transoesophageal echo-Doppler in a trial to differentiate the RV consequence of increasing lung volume from those secondary to increasing airway pressure during mechanical ventilation.

Methods Thirty stable patients on MV because of different causes were enrolled prospectively in this single center, cross-sectional clinical study. Each patient was firstly subjected to conventional ventilation (CV) with volume-controlled ventilation, followed by OLC ventilation by switching to a pressure-controlled mode, then a recruitment maneuver applied until PaO2/FIO2 >375 torr. Hemodynamic (MAP, CVP and HR) and respiratory (peak, plateau and mean airway pressure and total and dynamic lung compliance) measurements were recorded before, 20 minutes after a steady state of both CV and 20 OLC ventilation. Also, transoesophageal ECHO Doppler was performed at the end of inspiration and end of expiration to calculate the mean acceleration (ACmean), as a marker of the RV outflow impedance, 20 minutes after a steady state of both CV and OLC ventilation.

Results During inspiration, ACmean was significantly lower during CV compared with OLC ventilation (P < 0.001). Inspiration did not cause a significant decrease in ACmean, compared with expiration during OLV (P < 0.001) but did so during CV. In comparison with baseline and CV, OLC ventilation was associated with a statistically significant higher CVP (P < 0.001 for both), higher total quasi-static lung compliance (P < 0.001 for both) and dynamic lung compliance (P = 0.001 for both). Moreover, the PaO2/FIO2 ratio of OLV was significantly higher than in baseline and CV (P < 0.001 for both).

Conclusions OLC ventilation does not change RV afterload during inspiration and expiration as RV afterload appears primarily mediated through the tidal volume. Moreover, OLC ventilation provides a more stable hemodynamic condition and better oxygenation and lung dynamics.

Lung sound amplitude measured by vibration response imaging is influenced by the presence of secretions
S Lev1, AS Stern-Cohen1, MS Shapiro1, JC Cohen1, YG Glickman2, PS Singer1
1Rabin Medical Center, Beilinson Campus, Petach Tika, Israel; 2DeepBreeze Ltd, Or-Akiva, Israel

Introduction There is no valid estimation of the presence of airway secretions in mechanically ventilated patients. Secretions may amplify breath sounds by increasing turbulence in the airways or alternatively decrease breath sounds by obstructing air flow. Vibration response imaging (VRI) was recently suggested as a tool to assess secretion removal following physiotherapy [1]. The objective of our analysis was to describe the acoustic effects of secretion removal by measuring the lung sound amplitudes pre and post airway suction in both lungs.

Methods Twenty-two recordings pre-suction and 22 recordings post-suction (19 patients) were performed with VRI while the mode of ventilation remained constant. The sound amplitude measurements before and after the suction procedure were compared.

Results After suction a decrease in total lung sound amplitude was detected in all of the recordings. The lung sound amplitude of the right lung decreased significantly by 3.3-fold from 52.05 ± 16.11 to 15.54 ± 5.36 arbitrary units (AU) (mean ± SEM) (n = 22, P < 0.01). The left lung sound amplitude decreased by 2.4-fold from 28.42 ± 11.28 to 11.69 ± 3.15 AU (mean ± SEM) (n = 22, P < 0.01). The flow rate (measured by the VRI D-lite flow meter) of both lungs increased significantly after secretion removal (n = 22, P < 0.01). See Figure 1.

Conclusions The finding that the VRI signal amplitude decreased after a suction procedure in ventilated patients suggests that secretions are usually noisy. This effect was more pronounced on the right side.

Figure 1 (abstract P173). Lung sound amplitude of secretion removal (mean ± SEM).
probably due to expected more efficient secretion removal. We suggest that effective removal of secretions may be inferred by a combination of a decrease in VRI signal coupled with an increase in air flow rate.

Continuous elevation of lung sound amplitudes, recorded at fixed flow rate, may indicate an increase in lung water content

S Lev1, P Singer1, K Robinson1, K Højnowski2, L Wolloch3, L Gatto4, GF Nieman5

1 Rabin Medical Center, Beilinson Campus, Petach Tikva, Israel; 2SUNY Upstate Medical University, Syracuse, NY, USA; 3Deep Breeze Ltd, Or-Akiva, Israel; 4SUNY Cortland, Cortland, NY, USA

**Critical Care** 2011, Volume 15 Suppl 1

Introduction Vibration response imaging (VRI) is a bedside lung sound monitoring system. We previously reported that vibration intensity can be significantly elevated in patients with congestion, as opposed to pleural effusion, atelectasis, or normal lung [1]. We hypothesized that changes in lung water content (that is, pulmonary edema) may influence breath sound amplitude and explored the possibility of using continuous digitalized lung sound monitoring as a means to track changes in extravascular lung water (EVLW).

**Methods** EVLW was increased in three pigs: in two animals by installation of saline into the endotracheal tube, and in one animal with sepsis-induced edema. In both models the increase in extravascular lung water index (EVLWI) was evaluated by the PICCO system, and lung sound amplitude was monitored with the VRI. Animals were ventilated at a fixed flow rate.

**Results** In both the saline installation and sepsis animal models, significant elevation in lung sound amplitude was measured. In the saline installation animals, sound amplitude increased from 2.21 x 10^4 au to 9.49 x 10^5 au (average ± SEM), concomitant with an increase in EVLWI from 10 ml/kg to 14 ml/kg. Similarly, sound amplitudes changed in correspondence with elevation of EVLWI in the septic animal (see Figure 1).

**Conclusions** These preliminary results suggest that continuous elevation of lung sound amplitudes, recorded at fixed flow rate, may indicate an increase in lung water content.

**Reference**
degrees of PVA. The Edi peak (16.8 ± 7.6 mV) and Edi min (0.1 ± 1.3 mV) values were used to adjust the level of sedation. The analgesosedation quality was 97%.

Conclusions NAVA has been a real monitoring tool that provided a continuous dynamic lung overview. Monitoring NAVA avoided the more serious complications of the PVA: prolonged mechanical ventilation, barotrauma, and inadequate or excessive sedation. It was the only mode able to determine the asynchrony, allowing us to administer a tailored analgesosedation, until the suspension. Moreover this protocol permitted us to save valuable resources. The measurement of PVA is a priority for the optimal sedation and NAVA can become an indicator for rating of analgesosedation scales.

Early prognostic indices for weaning after long-term mechanical ventilation
A Temelkov, R Marinova, M Lazarov
Alexandrovskas University Hospital, Sofia, Bulgaria

Introduction A large number of predictive indices are used for evaluation of the capability for transition to spontaneous breathing in critically ill, mechanically ventilated patients. The great number of these indices and the difficulties in the interpretation causes significant obstacles and unclear points during the early attempts for transition to spontaneous breathing. In our study we investigated the role of predictive indices that are significant for weaning after long-term mechanical ventilation. The purpose is to determine predictive indices, which have early and significant predictive value concerning successful transition to spontaneous breathing.

Methods The study covers 45 critically ill patients who were mechanically ventilated for more than 7 days in our ICU. The weaning efforts were made through a T-circuit for spontaneous breathing according to the local protocol. The patients were allocated into two groups – group A (38 patients with successful 2-hour spontaneous breathing through a T-circuit) and group B (seven patients with unsuccessful 2-hour test of weaning with a T-circuit system). The monitored parameters in this period were: respiratory rate/tidal volume ratio (f/Vt), occlusive pressure (P0.1), inspiratory time/tidal time ratio (Ti/Ttot), pressure time index, pressure time product and work of breathing (WOBp) together with SAPS II score and clinical and paraclinical parameters, concerning successful weaning.

Results Clinical research of f/Vt and WOBp between the two groups gives a reliable index in transition to spontaneous breathing. Changes in P0.1, Ti/Ttot, pressure time index and pressure time product are later and thus less important in the early assessment of withdrawal after long-term mechanical ventilation.

Conclusions Respiratory rate/tidal volume ratio (f/Vt) and work of breathing (WOBp) are the earliest predictive indices for the possible outcome in the process of weaning after long-term mechanical ventilation.

Alveolar morphology depends on ventilator settings: lessons from in vivo alveolar microscopy under static and dynamic conditions
D Schwenninger, S Schumann, J Guttmann
University Medical Center Freiburg, Germany

Introduction In the context of lung-protective mechanical ventilation, knowledge about the global respiratory mechanics (for example, lung resistance and compliance) can be essential to guide the ventilatory therapy. From recent work it is known that the lung shows a significantly different mechanical behaviour when examined under static conditions (continuous ventilation interrupted by zero-fl ow or low-fl ow respiratory manoeuvres) compared with dynamic conditions (no interruption). However, the significance of this difference at the anatomical level of the alveoli has not yet been fully examined. This study aims to determine changes in morphology of subpleural alveoli under static and dynamic conditions in an animal model.

Methods A method for endoscopic intravital microscopy of lung tissue [1] was used to record videos of subpleural alveolar structures in vivo. The model. This specialized method allowed the continuously focused recording of the lung surface during any kind of respiratory manoeuvre, including continuous mechanical ventilation. Videos of alveolar structures were recorded during continuous mechanical ventilation (dynamic) at different levels of positive end-expiratory pressure (PEEP) and during low-fl ow manoeuvres (static) where the lung was slowly inflated up to an airway pressure of 40 mbar. Alveolar morphology was analysed using a dedicated semiautomatic image processing algorithm by tracking the change of area-size of the visible subpleural alveoli in the videos. The simultaneous change of area-size of different alveoli was averaged to get the mean alveolar area-size depending on the respective airway pressure. Comparison was done by calculating the difference of relative area-size increase in identical ranges of airway pressure under dynamic and static conditions.

Results Data from five animals mechanically ventilated at PEEP levels of 6 and 15 mbar showed a significantly smaller increase in area-size under dynamic compared with static conditions: 12% smaller at 6 mbar; 40% smaller at 15 mbar.

Conclusions Under dynamic conditions, the pressure-dependent change in alveolar morphology is significantly different compared with static conditions. We conclude that, to guide mechanical ventilation therapy, it is essential to determine respiratory mechanics under dynamic conditions.

Ventilatory ratio: validation in an ex vivo model and analysis in ARDS/ALI patients
P Sinha1, K Carrie1, A Bersten1, JG Hardman1, N Soni2
1Chelsea and Westminster NHS Foundation Trust, London, UK; 2Queen’s Medical Centre, Nottingham, UK; 3Flinders Medical Center, Adelaide, Australia; 4ANZICS CTG, Flinders Medical Center, Adelaide, Australia

Introduction Several indices exist to monitor adequate oxygenation, but no such index exists for ventilatory efficiency. The ventilatory ratio (VR) is a simple tool to monitor changes in ventilatory efficiency using variables commonly measured at the bedside [1]:

\[
VR = \frac{\text{V}_{\text{predicted}} \times P_{\text{O}_{2}/\text{p}}}{\text{V}_{\text{measured}} \times P_{\text{O}_{2}/\text{p}}}
\]

See Figure 1 overleaf (where predicted values are VE 100 ml/kg/minute and PaCO2 5 kPa).

Methods The Nottingham Physiology Simulator (NPS), a validated computational model of cardiopulmonary physiology [2], was used to validate the ability of VR to reflect ventilatory efficiency ex vivo. Three virtual patients were configured, representing healthy lung, ARDS and COPD. VR was calculated while minute ventilation, ventilation rate and VCO2 were each varied in isolation. The clinical uses of VR were then examined in a database comprising 122 patients with ALI and ARDS [3]. Standard respiratory data and VR values were analysed in all patients.

Results The NPS model showed significant correlation between VR and physiological deadspace fraction (Vd/Vtphys) at constant VCO2 (P < 0.001, r = 0.99). Similarly, VCO2 had a linear relationship with VR at constant Vd/Vtphys. Across the various ventilatory configurations the median values and ranges of calculated VR for the three patients were as follows: normal patient VR 0.89 (0.61 to 1.36), COPD 1.36 (0.95 to 1.89) and ARDS 1.73 (1.2 to 2.62). In the ALI/ARDS database the range
of values for VR was 0.56 to 3.93 (median 1.36). Patients with ARDS had a significantly higher VR in comparison with patients with ALI (1.44, 1.25 to 1.77 vs. 1.25, 0.94 to 1.6, P = 0.02). VR was significantly higher in nonsurvivors as compared with survivors (1.7 ± 0.64 vs. 1.45 ± 0.56, P < 0.03). There was poor correlation between PaO2/FiO2 ratio and VR in the population (r = −0.32, 95% CI = −0.47 to −0.15).

Conclusions Ex vivo modeling shows that VR can be simply and reliably used to monitor ventilatory efficiency at the bedside. VR is influenced by changing CO2 production and deadspace ventilation. As a clinical tool it is a predictor of outcome and is independent to PaO2/FiO2 ratio.

Therapy with recombinant human antithrombin, heparin and tissue plasminogen activator improves survival and reduces ventilation days in a long-term ovine model of cutaneous burn and smoke inhalation injury
S Asmussen, Y Yamamoto, DL Traber, H Ito, R Cox, H Hawkins, LD Traber, D Herndon, P Enkhbaatar
University of Texas Medical Branch, Galveston, TX, USA; 2Shriners Hospital for Children, Galveston, TX, USA

Introduction In this study we investigated the long-term effects of a combined therapy with recombinant human antithrombin (rHAT), heparin (hep) and tissue plasminogen activator (tPA) in our established model of acute lung injury, resulting from burn and smoke inhalation injury (BSII). We hypothesised that this triple therapy decreases the requirement of ventilation, reduces ventilation days and improves survival.

Methods Ten female sheep (34.4 ± 2.1 kg) were operatively prepared for chronic study, and were randomly allocated either to control or treatment groups (n = 5 each). After tracheostomy, BSII (48 breaths of cotton smoke) and third-degree burn of 40% total body surface area was performed under deep anesthesia. The sheep were mechanically ventilated and fluid resuscitated for 96 hours in an awake state. The therapy group received combined therapy of rHAT, nebulized heparin and nebulized tPA. The continuous i.v. infusion of 0.7 mg/kg/hour rHAT was started 1 hour post-injury. The nebulizations of 5,000 IE heparin every 4 hours were started 2 hours post-injury and 2 mg tPA were nebulized every 4 hours, starting 4 hours post-injury. The treatment was stopped at 48 hours. Ventilator weaning was started at 48 hours, if PaO2/FiO2 ratio ≥250. The control group received saline nebulization. Measurements were taken in intervals ranging from 3 to 12 hours. Statistical analysis: two-way ANOVA and Bonferroni post-hoc comparison. Data are expressed as mean ± SEM. Significance P < 0.05.

Results The PaO2/FiO2 ratio was significantly decreased in the control group versus baseline (BL: 530 ± 16 vs. 96 hours: 267 ± 51). The ratio showed significantly higher values in the treatment versus control sheep (96 hours: 377 ± 32). All treated sheep survived and were weaned from the ventilator. Four out of five treatment sheep could be decannulated from the tracheostomy tube at 72 hours. Only three out of five control sheep survived 96 hours and none of the control sheep could be weaned from the ventilator.

Conclusions This triple therapy with nebulization of heparin and tPA and intravenous application of rhAT may be a novel and efficient therapeutic alternative to improve the outcome of burn patients with smoke inhalation injury.

P181
Hypercapnic acidosis transiently weakens hypoxic pulmonary vasoconstriction in anesthetized pigs, without affecting the endogenous pulmonary nitric oxide production
MC Nilsson1, A Larsson1, K Hambraeus-Jonzon2
1Surgical Sciences, Uppsala, Sweden; 2Karolinska University Hospital, Stockholm, Sweden

Introduction Hypercapnic acidosis is often seen in critically ill patients and during protective mechanical ventilation. Conflicting findings regarding the effect of hypercapnic acidosis on endogenous nitric oxide (NO) production and hypoxic pulmonary vasoconstriction (HPV) have been reported. The aim of this study was to test the effects of hypercapnic acidosis on HPV, and the endogenous NO production in hypoxic and hyperoxic lung regions.

Methods Sixteen healthy anesthetized pigs were separately ventilated with hypoxic gas to the left lower lobe (LLL) and hyperoxic gas to the rest of the lung. The pigs were then randomized into two groups. Eight pigs received 10% CO2 inhalation (Hypercapnia group) to both lung regions, and eight pigs served as the Control group. The NO concentration in exhaled air (ENO), nitric oxide synthase (NOS) activity in lung tissue, and regional pulmonary blood flow were measured.

Results There were no significant differences between the Hypercapnia and Control groups for ENO, Ca2+-independent, or Ca2+-dependent NOS activity in hypoxic or hyperoxic lung regions. The relative perfusion to the hypoxic LLL (QLLL/QT) increased during the first 90 minutes of hypercapnia from 6 (1)% (mean (SD)) to 9 (2)% (P < 0.01), and then decreased to the same level as in the Control group where QLLL/QT remained unchanged over time (P > 0.05). In addition, hypercapnia increased cardiac output (QT) (P < 0.01), resulting in increased oxygen delivery (P < 0.01), despite a significant decrease in PaO2 (P < 0.01). No changes were observed in pulmonary blood flow in either of the groups.

Conclusions Hypercapnic acidosis does not affect the endogenous pulmonary NO production, nor does it potentiate HPV.

Stenotrophomonas maltophilia in the respiratory tract of medical ICU patients
B Saugel, K Eschermann, R Schmid, W Huber
Klinikum Rechts der Isar, München, Germany

Introduction Stenotrophomonas maltophilia can cause pneumonia in critically ill patients. The aim of the study was to investigate characteristics of critically ill patients with S. maltophilia isolated from the respiratory tract and to identify risk factors for S. maltophilia pneumonia and ICU mortality and to analyze antibiotic susceptibility of S. maltophilia.

Figure 1 (abstract P179). Chi-squared test for trends P = 0.0015.
Methods A retrospective analysis of medical records (November 2005 to December 2009) for three medical ICUs in a university hospital.

Results Sixty-four patients with *S. maltophilia* isolated from the respiratory tract (median age 66.0 years). Thirty-six patients fulfilled the criteria for diagnosis of pneumonia. Mechanical ventilation was needed in 51 patients. A significantly higher lung injury score was observed in patients with pneumonia compared with patients with colonization (P = 0.010). Independent risk factors for *S. maltophilia*-related pneumonia were higher Sequential Organ Failure Assessment (SOFA) score (P = 0.009) and immunosuppression (P = 0.014). Patients with *S. maltophilia* pneumonia had higher ICU mortality within a follow-up of 28 days (P = 0.040) and higher hospital mortality (P = 0.018) than patients with colonization. The highest antibiotic susceptibility rates were observed to trimethoprim-sulfamethoxazole, tigecycline, and moxifloxacin. A higher SOFA score when *S. maltophilia* was isolated (P = 0.001) and development of renal failure (P = 0.021) were independent risk factors for ICU mortality.

Conclusions Higher SOFA score and immunosuppression are independent risk factors for *S. maltophilia* pneumonia. Patients with pneumonia caused by *S. maltophilia* have a significantly higher ICU mortality within a follow-up of 28 days, hospital mortality and lung injury score compared with patients with *S. maltophilia* colonization.

P183 Hospital-acquired pneumonia is associated with deficient γc-cytokine gene expression
M White, R McMansion, T Ryan
St James Hospital, Dublin, Ireland; Trinity College, Dublin, Ireland

Introduction Lymphocyte homeostasis is dependent on the γc cytokines. We hypothesised that infection in humans is associated with differential gene expression of the γc cytokines and their associated apoptosis mediators.

Methods Sixty patients undergoing elective lung resection surgery were recruited. Nineteen patients developed postoperative pneumonia. Pneumonia was diagnosed by CDC NNIC criteria. Gene expression in peripheral blood leukocytes (PBLs) of IL-2, IL-7, IL-15 and IFNγ, Bax, Bim, Bcl-2 was determined by qRT-PCR preoperatively and again on day 1 and day 5 postoperatively. IL-2 and IL-7 serum protein levels were determined by ELISA preoperatively and again on day 1 and day 5 postoperatively.

Results In lung resection surgery patients, postoperative pneumonia was associated with a perioperative decrease in IL-2 mRNA (P < 0.0001) and IL-7 mRNA (P = 0.003). IL-15 gene expression was similar between both groups at all three points. Bcl-2 and Bax gene expressions were similar between both pneumonia and nonpneumonia groups at all three time points. Bim gene expression was greater in the pneumonia group compared with the nonpneumonia group on day 5 postoperatively (P = 0.04). IL-2 protein levels were similar in pneumonia and nonpneumonia groups. IL-7 protein levels were similar in all groups.

Conclusions Patients with postoperative pneumonia display deficient IL-2 and IL-7 gene expression in PBLs. aberrant cytokine gene expression may precede the onset of infection.

P184 Clinical aspects and predictors of mortality of *Pseudomonas aeruginosa* pneumonia in a cohort of critically ill patients
G De Pascale, F Antonicelli, R Maviglia, A Cataldo, R Festa, F Idone, EM Trecarichi, MA Pennisi, M Tumbarello, M Antonelli

Introduction *Pseudomonas aeruginosa* (PA) pneumonia (PN) represents a serious complication of long-term hospitalization [1]. The aim of our study is to analyze the clinical characteristics and predictors of mortality of PAPN in critically ill patients.

Methods All patients admitted to the 18-bed ICU of our university hospital between 1 January 2009 and 30 June 2010, affected by PAPN, were retrospectively enrolled in a cohort study.

Results Over the study period 1,109 patients were admitted and 322 bacterial PN were diagnosed. Sixty-five PAPN occurred: 52 ICU-acquired (ICUa) and 13 non-ICU-acquired (nICUa). Patients were mainly admitted because of a medical condition (71%), with a median length of ICU stay of 29.2 ± 27.6 days. The median SAPS II and SOFA scores were 40 ± 13.5 and 6.2 ± 3. A total of 35.4% of PA were isolated were multidrug-resistant (MDR), 49.2% of patients with PAPN received a >24 hour delayed adequate antimicrobial treatment (DAAT >24 hours) and 57% received an anti-pseudomonas combination therapy; 25 patients (38.5%) died in the ICU. Comparing patients with ICUaPN with those with nICUaPN, the former group were younger (P < 0.01), with a longer length of ICU stay (P < 0.01), more frequently admitted for a traumatic reason (P = 0.02) and presented less severe SAPS II (P < 0.05). The independent risk factors associated with ICU mortality are listed in Table 1.

Conclusions PA has appeared as a relevant respiratory pathogen in our cohort of critically ill patients, either in ICU or pre/ICU settings. Patients’ (baseline clinical condition), PA (MDR) and physicians’ (DAAT >24 hours) related factors can influence the outcome of PN. The knowledge of local bacterial epidemiology and the prompt use of an anti-pseudomonas empiric treatment in patients with recognized PA risk factors could improve the outcome of severe MDR PAPN.

P185 Safety and efficacy of intratracheal DNase with physiotherapy in severe status asthmatics
A Nyman, K Puppala, S Colthurst, S Parsons, S Tibby, I Murdoch, A Durward

Introduction Diffuse airway plugging with thick viscous secretions is recognised in acute severe asthma, and contributes to airflow limitation in ventilated asthmatics. Since 2004, we have used intratracheal DNase with physiotherapy as second-line therapy in mechanically ventilated children with severe status asthmatics who are refractory to conventional medical management. Our aim is to report the safety profile and efficacy of intratracheal DNase mucolytic therapy in this cohort.

Methods A retrospective cohort analysis in a 20-bed PICU. Forty-six ventilated children, median (IQR) age 74 months (45 to 141), received intratracheal DNase with physiotherapy (January 2004 to August 2010). Indication for DNase was peak inspiratory pressure (PIP) > 28 cmH2O with hypercarbic acidosis (pCO2 > 10 kPa). Eleven patients required additional doses of DNase. In 40 episodes DNase was given blindly (n = 40) or bronchoscopically (n = 17).

Results The median (IQR) time to DNase following PICU admission was 2.1 hours (1.3 to 3.8). At the time of DNase, median PIP was 34 cm (30 to 40), pH was 7.12 (7.01 to 7.22) and pCO2 was 11 kPa (7.9 to 14.1). Overall DNase produced an improvement in ventilation (see Figure 1). Salbutamol IV was constant at 1 μg/kg/minute (0.5 to 2). The therapy was well tolerated with no hypoxia or hypotensive episodes, or air leaks. Median length of ventilation was 22 hours (15 to 37). No patient required extracorporeal membrane oxygenation and there were no deaths.
Conclusions Intratracheal DNase with physiotherapy is safe and effective therapy for refractory ventilated patients with status asthmatics. A randomised control trial is warranted.

Relation between mortality rate, duration of hospitalization and levels of TNFα, IL-6 and catalase at admission of cases to the emergency department with COPD attack
A Bayır1, P Büyükünaldı2, A Kıyıcı1, A Akı1, F Kara1
1Selçuk University, Selçuklu Faculty of Medicine, Konya, Turkey; 2Selçuk University, Meram Faculty of Medicine, Konya, Turkey

Introduction The aim of the study was to investigate the relation between the mortality rate, the hospitalization period in the emergency department or ICU and the obtained levels of TNFα, IL-6 and catalase before they underwent attack treatment at admission of the cases applying to the emergency department with COPD attack.

Methods The cases diagnosed with COPD before and who applied to the emergency department with COPD attack were included in the study. Venous blood samples were obtained to evaluate the levels of TNFα, IL-6, catalase, leucocyte, sedimentation and CRP when the cases applied to the emergency department. Their hospitalization in the service or ICU, the follow-up period in mechanical ventilation and leaving hospital (dead or discharged) were followed. The mean levels of TNFα, IL-6, catalase, leucocyte, sedimentation and CRP values were compared with the average period of hospitalization in the service or ICU and with each other. The Mann–Whitney U test and chi-square test were used as nonparametric tests. P ≤0.05 values were regarded as significant.

Results All of the cases that died (n = 7) were followed in intensive care, they underwent invasive mechanical ventilation treatment and their mean hospitalization period was 25 days. The cases discharged (n = 80) were all followed in the service and their average hospitalization duration was 6.2 days. Non-invasive mechanical ventilation was applied to 12 of these cases. Of the dead cases, the mean leukocyte value was 12.665, sedimentation 29.68, CRP 49.7, TNFα 27.3, IL-6 32 and catalase was 81. Of the cases discharged, the mean leukocyte value was 10.4, sedimentation 19.0, CRP 49.7, TNFα 29.3, IL 13.6 and catalase was 62. In 85 cases, the mean value of leukocyte, sedimentation, CRP and IL-6 of the dead cases were significantly higher than those of the cases in the discharged group (P = 0.040, 0.038, 0.02, 0.017, respectively).

Conclusions A high level of leukocyte, sedimentation, CRP values and low IL-6 values at the admission of cases with COPD attack to the emergency department may indicate the requirement to follow in the ICU and treatment with mechanical ventilation, and a high mortality rate.

P187
Induced hypothermia is protective in a rat model of pneumococcal pneumonia
C Beurskens, H Aslami, M Kuijpers, M Schultz, N Juffermans
Academic Medical Centre, Amsterdam, the Netherlands

Introduction Induced hypothermia is protective in ischemia–reperfusion injury by reducing the inflammatory response and is increasingly applied in the ICU. Hypothermia may dampen host response during an infection and it is believed that induced hypothermia may carry the risk of acquiring or aggravating an infection. We investigated the effect of hypothermia on bacterial outgrowth and on the inflammatory response in a rat model of pneumococcal pneumonia.

Methods Sprague–Dawley rats (350 to 400 g) were inoculated intratracheally with ~5.5 x 10^6 cfu of Streptococcus pneumoniae, controls received saline. After 40 hours, the animals developed pneumonia and mechanical ventilation was started via a tracheotomy. Hypothermia (32°C) was induced using ice packs on the abdomen. In controls, normothermia was maintained by a thermomattress. After 4 hours, rats were sacrificed, bronchoalveolar lavage fluid (BALF) was obtained and blood and organs were collected. Data are shown in percentages or median (range).

Results Induced hypothermia reduced pulmonary inflammation during pneumonia, exemplified by a reduction in pulmonary cell influx (1.3 (0.8 to 1.6) x 10^6 vs. 3.1 (1.6 to 4.6) x 10^6 mg/ml, hypothermia vs. normothermia; P < 0.05) and BALF protein levels (0.9 (0.6 to 1.3) vs. 1.5 (1.4 to 1.6) mg/ml; P < 0.05). Hypothermia also reduced BALF levels of IL-1 (0.4 (0.1 to 0.6) vs. 0.8 (0.6 to 0.9) ng/ml; P < 0.05), but had no effect on BALF levels of CINCS and IL-6. Hypothermia, however, did not affect bacterial outgrowth in the BALF (1.4 (0.3 to 2.0) vs. 0.5 (0.2 to 5.2) x 10^6 cfu/ml; P = NS) nor in homogenized lungs (13.5 (2.0 to 69.2) vs. 0.8 (0.1 to 14.5) x 10^6 cfu/g; P = NS). Hypothermia tended to reduce bacterial dissemination to the blood (38 vs. 50%, P = NS), spleen (0 vs. 50% culture positivity, P = 0.08) and liver (38 vs. 63% culture positivity, P = NS).

Conclusions Although hypothermia reduces pulmonary cell influx and protein leakage, it does not affect local bacterial outgrowth during pneumonia and even tends to reduce bacterial dissemination in this animal model of pneumococcal pneumonia. In contrast to current belief, induced hypothermia seems protective in a model of pneumococcal pneumonia.

P188
Incidence of and risk factors for nonrespiratory acute organ failure in ICU patients receiving respiratory support: a pilot international cohort study
M Tertblanche1, A Smith2, E Recchia2, M Harward2, J Gilfeather2, D McAuley2
1King’s College London, UK; 2Royal London Hospital, London, UK; 3St Thomas’ Hospital, London, UK; 4Princess Alexandra Hospital, Brisbane, Australia; 5Altnagelvin Hospital, Londonderry, UK; 6QUB, Belfast, UK

Introduction Strategies to prevent the progression to nonrespiratory multiorgan failure (nRAOF) in patients receiving invasive or non-invasive ventilation are needed. We performed a pilot international prospective cohort study to determine the incidence of and risk for nRAOF in ICU patients receiving respiratory support.

Methods All consecutive ICU admissions to 11 ICUs (UK, Australia and Canada) were screened during the first 24 hours over a 4-week period. Patients receiving positive pressure ventilatory support for at least 1 hour during the first 24 hours were eligible. Those with nRAOF (SOFA 3 to 4), or elective post-surgical patients extubated and ready for discharge within 24 hours after admission, were excluded. Follow up lasted for the first of 14 days after enrolment or ICU discharge.

Results In total, 123/766 (16.1%) patients were enrolled. Evasive postoperative ventilation (22.1%) and type 1 respiratory failure (29.5%) were the most frequent indications for respiratory support, n = 49 (39.8%, 95% CI = 31.1 to 48.6%) developed nRAOF after an average 3.7 (SD 1.5) days. The 28-day ICU mortality was 8.1%. In univariate analysis, APACHE II > 14.5 (OR = 3.0, 95% CI = 1.2 to 7.1) and nonrespiratory SOFA score > 1 (OR = 2.3, 95% CI = 1.1 to 4.7 excluding GCS) were associated (P < 0.05) with AOF. See Table 1.

AOF, acute nonrespiratory organ failure; SOFA, excluding respiratory and GCS.

Conclusions Nearly 4/10 developed AOF, but the treatment window is relatively small. APACHE II and baseline SOFA may predict risk. These data inform future trials of preventive strategies but a study with more outcome events is needed to reduce the confidence intervals.

P189
Pharmacological randomized controlled trials in acute respiratory distress syndrome mortality
C Santoscu, C. Canascio, G. Mestica, G. Foti, A. Pesenti
1. Fondazione Azienda Ospedaliero Universitaria Careggi, Florence, Italy; 2. Hospital Valladolid, Spain; 3. Erasme Hospital, Brussels, Belgium

Introduction Acute lung injury and acute respiratory distress syndrome are common conditions encountered in the ICU. Whether mortality has decreased over time or not, they are still many unanswered questions about the impact of pharmacological treatment on ALI/ARDS mortality.

Methods The objectives were to perform a review of the literature in search of the randomized control trials that assess the pharmacological impact in ALI/ARDS on all-cause mortality. We included all RCTs of pharmacological treatments in ALI/ARDS that had an impact in mortality in adults. We excluded RCTs that included patients <18 years old and animals. We also excluded trials that tested fluid therapy, mechanical ventilation, nonpharmacological treatments, antibiotics and reviews. No date or language restriction was applied.

Results We included 37 RCTs involving 6,303 patients in different ALI/ARDS treatments modalities: steroids (n = 271), enteral nutrition (n = 411), surfactant (n = 1,754), nitric oxide (n = 1,342), APC (n = 75), muscle relaxants (n = 340), prostaglandins (n = 550), NAC (n = 127), silvestat (n = 492), rPAF-HD (n = 127) lisofylline (n = 235), rVIIa antagonist (n = 214), OTZ (n = 215) and verapamil-propacome-procaine compound (n = 150).

Conclusions Only steroid treatment (methylprednisolone) and nutritional therapy (EPA + GLA + antioxidants) showed a trend towards reduced mortality. Other treatments were associated with reduced morbidity. However, many empirical treatments are still used in day-to-day practice.

Positive end-expiratory pressure improves oxygenation inducing ventral-to-dorsal tidal ventilation redistribution: an electrical impedance tomography study
T Mauri1, G Bellani1, A Pradella1, A Grassi1, P Tagliabue2, M Bombino1, N Patroniti1, G Foti1, A Pesenti1
1.Universita degli Studi di Milano-Bicocca, Monza, Italy; 2.Intensive Care Medicine, Monza, Italy

Introduction Positive end-expiratory pressure (PEEP) improves oxygenation in acute lung injury (ALI) patients by increasing end-expiratory lung volume (EELV). Electrical impedance tomography (EIT) is a relatively new non-invasive bedside method to monitor regional distribution of tidal ventilation and EELV changes, validated in preclinical studies. We tested EIT as a monitor of PEEP-induced tidal redistribution and EELV changes in ALI patients, and the relationship between EIT parameters and oxygenation.

Methods We enrolled 14 consecutive ALI patients admitted to our ICU, intubated and undergoing mechanical ventilation. We monitored the regional tidal ventilation distribution by means of a new EIT system (PulmoVista 500® Dräger Medical GmbH, Lübeck, Germany) dividing the lung imaging field into four contiguous same-size regions of interest (ROIs): ventral right (ROI 1) and left (ROI 2) and dorsal right (ROI 3) and left (ROI 4). EIT allowed us to measure changes in EELV at different PEEP levels by measuring differences in end-expiratory total lung electrical impedance. We randomly performed the following two steps for 15 minutes, leaving tidal volume and FiO2 unchanged: PEEPlow (clinical) and PEEPhigh (PEEPlow + 5 cmH2O). At the end of each step, we recorded: ventilation parameters, arterial blood gas analysis, percentage of tidal ventilation distribution in the four ROIs and EELV change. Analyses were performed by paired t-test and linear regression.

Results Patients were 55 ± 12 years old and seven were women. ALI etiology was: trauma (14%), septic shock (21%), pneumonia (37%) and postoperative respiratory failure (28%). PEEPlow was 7 ± 2 cmH2O and PEEPhigh was 12 ± 3 cmH2O. At PEEPlow PaO2/FiO2 significantly ameliorated (266 ± 98 vs. 287 ± 102 mmHg, P = 0.0003), the proportional distribution of tidal ventilation changed in all four ROIs (ROI 1 to ROI 4: 34 ± 14 vs. 30 ± 14, P = 0.03; 33 ± 13 vs. 30 ± 11, P = 0.12; 16 ± 9 vs. 20 ± 10, P = 0.002; 17 ± 7 vs. 21 ± 6%, P = 0.002), moving from ventral to dorsal, and EELV increased by 349 ± 121 ml. Changes in PaO2/FiO2 correlated better with ventral-to-dorsal shifts of tidal ventilation than with EELV changes (r = 0.499, P = 0.08; r = −0.399, P = 0.18).

Conclusions EIT allowed us to detect ventral-to-dorsal tidal ventilation redistribution at higher PEEP levels. This mechanism may be a key determinant of PEEP-induced oxygenation improvement.

P191
Neurally adjusted ventilatory assist reduces asynchrony and patient effort in severe acute respiratory distress syndrome patients undergoing extracorporeal membrane oxygenation
T Mauri1, G Bellani1, A Confalonieri1, F Magni1, G Grasselli2, N Patroniti1, A Pesenti1
1.Universita degli Studi di Milano-Bicocca, Monza, Italy; 2.San Gerardo Hospital, Monza, Italy

Introduction Assisted ventilation may prevent muscle atrophy and reduce sedation needs in severe acute respiratory distress syndrome (ARDS) patients undergoing extracorporeal membrane oxygenation (ECMO). However, pressure support (PS) is difficult to implement in these patients: inspiratory flow peaks and drops rapidly and the ventilator expiratory phase may overlap patient inspiration causing asynchrony and barotrauma. Neurally adjusted ventilatory assist (NVA) is an assisted ventilation mode driven by diaphragmatic electrical activity (EAdi) and should adapt better to patients’ respiratory pattern. We measured whether NVA could reduce asynchrony in severe ARDS patients undergoing ECMO.

Methods We enrolled seven consecutive adult patients undergoing ECMO for severe ARDS. Twenty-four hours after their ventilation mode was switched from controlled to assisted, we randomly tested the following strategies for 30 minutes each, leaving positive end-expiratory pressure (PEEP), FiO2, and ECMO settings unchanged: (1) PS with expiratory trigger at 30% of flow peak value (PS30); (2) PS with expiratory trigger at 1% (PS1); (3) NVA. The PS level and NAVA gain were chosen to obtain a similar tidal volume (VT). From continuous recordings of airway pressure, flow, volumes and EAdi we calculated the average VT, respiratory rate (RR) and asynchrony index (AI: number of asynchrony events / ventilator cycles + wasted efforts) x 100) of each step and, at the end, we measured arterial blood gases and pO2. Data are the median (IQR) and were compared by nonparametric Friedman test and linear regression.

Results At enrolment, patients were 44 (42 to 56) years old. Respiratory system compliance (Crs) was 12 (9 to 23) ml/cmH2O, PEEP 10 (7 to 12) cmH2O, FiO2 0.5 (0.4 to 0.5) and Vt 2.9 (2.8 to 4) ml/kg. Patients were on 3.2 (2.9 to 3.6) l/minute venovenous ECMO since 22 (16 to 29) days. Switching from PS30 to PS1 to NAVA, PaO2/FiO2 did not change
(P = 0.817), P1 was reduced (3.1 (2.6 to 5.7) vs. 2.1 (1.8 to 3.2) vs. 1.6 (0.9 to 2.3) cmH2O, P = 0.003) together with RR (P = 0.129) and AI (55 (29 to 66) vs. 46 (26 to 56) vs. 16 (8 to 18)), P = 0.004). The difference between AI during PS30 and NAVA was significantly correlated with Crs (R² = 0.87, P = 0.02).

Conclusions Implementation of NAVA in severe ARDS patients undergoing ECMO may decrease patient effort and asynchrony events. The advantage of NAVA over PS is more evident in patients with lower Crs.

P192
Danger signal uric acid is involved in ventilator-induced lung injury pathogenesis
M Kuipers, H Aslami, T Van der Poll, M Schultz, C Wieland
Academic Medical Centre, Amsterdam, the Netherlands

Introduction Endogenous molecules released during tissue injury can trigger an innate immune response and are termed damage-associated molecular patterns (DAMPs). Uric acid is considered an important DAMP and causes acute lung inflammation when administered locally. The exact role of the innate immune response in ventilator-induced lung injury (VILI) is not yet completely understood. We hypothesized that uric acid is released during VILI and that reduction of uric acid levels attenuates lung injury induced by short-term mechanical ventilation (MV).

Methods Uric acid levels in bronchoalveolar lavage fluid (BALF) of wildtype C57BL/6 mice ventilated for 5 hours with low tidal volume (LVT ~7.5 ml/kg) or high tidal volume (HVT ~15 ml/kg) and spontaneously breathing mice were determined. In addition, mice were treated with allopurinol (25 mg/kg; inhibits uric acid synthesis) or uricase (0.2 mg/kg; degrades uric acid) or vehicle (10% DMSO), 1 hour before start of HVT MV. Endpoints of VILI were lung wet/dry ratio, total protein, IgM and sRAGE concentrations in BALF as well as neutrophil influx and pulmonary cytokine and chemokine levels.

Results Injured MV leads to uric acid release in BALF of previously healthy mice. HVT ventilation significantly increased all endpoints of VILI as compared with the ventilated control group. Allopurinol and uricase treatment significantly decreased the wet/dry ratio and alveolar protein leak as compared with the HVT ventilated vehicle-treated group. IgM levels were also significantly lower in the allopurinol-treated group indicating protection of alveolar barrier function. Reduction of lung injury by allopurinol and uricase treatment was also demonstrated by the reduction of sRAGE concentrations, a marker of alveolar type I cell injury. Interestingly, treatment in the HVT group with allopurinol or uricase did not significantly reduce neutrophil influx or cytokine and chemokine levels.

Conclusions The danger signal uric acid is released due to injurious mechanical ventilation. Reduction of uric acid concentrations with allopurinol or uricase decreased VILI and specifically epithelial injury and alveolar barrier dysfunction.

High-frequency oscillatory ventilation in adults: experience in Chile
SU Ugarte, CR Rojas, CH Herrera
Clinica INDISA, Santiago, Chile

Introduction The aim was to describe the epidemiological profile of adult patients who were treated with HFOV like a rescue method after conventional mechanical ventilation failure, during 2009 in our ICU, in Santiago, Chile, and to describe patient characteristics, HFOV strategies and outcomes.

Methods A descriptive study. We evaluated the medical record of all adult patients treated with HFOV during 2009 at Clinica INDISA. We evaluated sex, age, associated co-morbidities, laboratory test results and main diagnosis at ICU admission, hours in conventional mechanical ventilation previous to HFOV connection, indication of HFOV, laboratory test results at the connection time to HFOV, and patient outcome.

Results A total of 15 patients were treated with HFOV during 2009 in our ICU; the mean age was 47 years, being 80% men. Three patients did not have, at ICU admission or during the course of the current hospitalization, description of associated co-morbidities, while 53.3% had report of two or more co-morbidities. The main diagnosis at ICU admission was severe pneumonia (53.3%) with a mean APACHE II score of 27.7. The mean values for PaFi and IOX prior to HFOV connection were 108.8 and 25, respectively. The main indication observed in those patients was very high FiO2 requirement to achieve an adequate arterial oxygen saturation (60% of the cases). Twenty percent of the sample required reconnection to HFOV, the mortality in this group of patients was 100%. Of all patients that were exposed to HFOV, there was an effective weaning to CMV and medical discharge in 40% of them, while the mortality during HFOV was 60%.

Conclusions We present the epidemiological profile of the patients exposed to HFOV during 2009 at our medical center, the mean age at admission was 47 years old; the main diagnosis was severe pneumonia, 40% of all patients survived. HFOV has beneficial effects on PaFi/FiO2, ratios and IO, and may be an effective rescue therapy for adults with severe oxygenation failure. This is the first study of its kind at a national level.

Stress–strain relationship in pulmonary cells under bidirectional stretch application
K Gameraenderg, S Schumann, F Wernet, E Faehnrich, M Schneider, J Uuttann University Medical Center, Freiburg, Germany

Introduction Analysing the effects of mechanostimulation on pulmonary cells improves the understanding of the stress–strain relationship in the lungs. While there are plenty of different methods to apply strain on cells and thereby to analyze intracellular and extracellular processes, it remains difficult to measure the resulting strain, in other words the forces produced by cells to counteract the applied strain. Recently we presented a bioreactor to cyclically deflect cells by co-deflecting them with a carrier membrane [1]. The air-tight highly pliant siloxane-carrier membranes [2] used in our bioreactor were modified with Sulfo-SANPAH and RG peptide [3] to allow cell adherence. Here we present actual data demonstrating changes in mechanical properties of pulmonary cell monolayers as a response to strain levels of up to 20% surface increase.

Methods Different alveolar epithelial cell lines (A549 and RLE-6TN) were grown on RGD-coated, highly flexible polydimethyl siloxane membranes and were mechanically stimulated in a bioreactor [1,2]. After becoming 100% confluent, microscopic images of cell monolayers were taken before subjecting them to increasing sinusoidal mechanical strain of up to 20% surface increase. The resulting stress was measured as the force that the cells opposed to the applied strain. Immediately after the procedure, additional images of cells were taken.

Results Stretching pulmonary cells bidirectionally led to a loss of intercellular connections and/or loss of integrin-binding sites to the RGD-labeled carrier membranes as indicated by comparing microscopic images before and after application of strain to cell monolayers. This was accompanied by a loss of the cell’s counterforce on strain.

Conclusions The investigation of cell forces with our strain applicator allows us to analyze mechanical properties of cell constructs at the same time as we can track visually changes in cellular morphology. Strain-related cell damages as found in this study could play a role in development of ventilator-induced lung injury.

Optimal positive end-expiratory pressure in mechanically ventilated patients: a clinical study
A Sundaram1, JG Chase1, CE Hann2, GM Shaw2
1University of Canterbury, Christchurch, New Zealand; 2Christchurch Hospital, Christchurch, New Zealand

Introduction
The optimal level of positive end-expiratory pressure (PEEP) is still widely debated in treating acute respiratory distress syndrome (ARDS) patients. Current methods of selecting PEEP only provide a range of values and do not provide unique patient-specific solutions. Model-based methods offer a novel way of using non-invasive pressure–volume (PV) measurements to estimate patient recruitability. This paper examines the clinical viability of such models in pilot clinical trials to assist therapy, optimise patient-specific PEEP, and assess the disease state and response over time.

Methods
Ten patients with acute lung injury or ARDS underwent incremental PEEP recruitment manoeuvres. PV data were measured in increments of 5 cmH2O and fitted to the recruitment model using volume-controlled ventilation. Inspiratory and expiratory breath holds were performed to measure airway resistance and auto-PEEP. Three model-based PEEP values were used to optimise PEEP based on the opening pressures (TOP), threshold closing pressures (TCP) and net recruitment. ARDS status was assessed by model parameters capturing recruitment and compliance. Two patients underwent multiple recruitment manoeuvres over time and four model metrics reflected and tracked the state or their ARDS.

Results
Median model fitting error across all patients for inflation and deflation was 2.8% and 1.02%, respectively, with all patients experiencing auto-PEEP. In all three metrics cases, model-based optimal PEEP was higher than clinically selected PEEP. Ranges for optimal PEEP were (5, 27), (10, 25) and (10, 30) cmH2O for TOP, TCP and net recruitment metrics, respectively. Disease-tracking metrics corresponded with the physiological status of two patients, indicating the potential for tracking disease state. In particular, monitoring TOP, standard deviation, TOP gradient and TCP gradient reflected compliance and recruitability changes as a function of time. Normalised SD reflected compliance changes in an exponential manner with the equation 72.6 x exp–0.0664 x SD, tracking disease state. In particular, monitoring TOP, standard deviation, TOP gradient and TCP gradient corresponded with the physiological status of two patients, indicating the potential for tracking disease state. In particular, monitoring TOP, standard deviation, TOP gradient and TCP gradient reflected compliance and recruitability changes as a function of time. Normalised SD reflected compliance changes in an exponential manner with the equation 72.6 x exp–0.0664 x SD, tracking disease state.

Conclusions
Flow-balanced expired during mechanical ventilation reduces oedema formation in the injured lung. Reduced expiratory peak flow and increased mean airway pressure during expiration are likely to have contributed to this beneficial effect.

Positive changes in the continuous desaturation index during mechanical ventilation are associated with mortality due to acute respiratory failure
GV Vazquez de Anda1, S Larraza1, J Talavera1, L De la Cruz Avila1, H Lopez1, D Rodriguez2
1Universidad Autonoma del Estado de Mexico, Toluca, Mexico; 2Hospital Materno Perinatal Monica Petoelini del Instituto de Salud del Estado de Mexico, Toluca, Mexico; 3Centro Medico del Instituto de Seguridad Social del Estado de Mexico y Municipios, Toluca, Mexico

Introduction
We have previously shown that the desaturation index (DI) and the continuous desaturation index (CDI) displayed on the desaturation index monitoring system (DIMS) have a high sensitivity and specificity to identify lung dysfunction [1,2]. However, dynamic changes during mechanical ventilation (MV) that may reflect the patient’s response for MV treatment have not yet been tested.

Methods
Fifty-eight patients with and without ALI/ARDS were followed during the first 24 hours of MV with the DIMS. The system computes the CDI from the positive end-expiratory pressure (PEEP), the inspired fraction of oxygen (FiO2) and arterial saturation by pulse oximetry (Sao2) [1,2]. The CDI is a percentage that is displayed graphically and is calculated moment by moment from the initial (first hour) CDI. Group (G) I (n = 16), CDI above 90%. GII (n = 22), CDI between 70 and 90%. GIII (n = 20), CDI below 70%. Then, changes in the CDI were calculated every hour (CDIh1 minus CDIh2, CDIh2 minus CDIh3, and so forth), three types of changes were expected: no change (even), negative changes (improvement of lung function) and positive changes (worsening of lung function). The mean of CDI changes was calculated at 6, 12, 18 and 24 hours after the initial recording. All patients were followed and mortality was associated with acute respiratory failure (ARF) was recorded.

Results
Changes (mean ± standard deviation) at 6 hours for GI: –1.82 ± 4.2, GII: –2.27 ± 9.2 and GIII: 2.52 ± 5.2 (P = 0.061). At 12 hours: GI: –2.2 ± 4.9, GII: –2.2 ± 9.1 and GIII: 6.07 ± 13.7 (P = 0.014). At 18 hours: GI: –1.36 ± 5.2, GII: –4.24 ± 11 and GIII: 5.47 ± 19.2 (P = 0.068). At 24 hours: GI: –2.09 ± 4.7, GII: –4.24 ± 12.8 and GIII: 8.53 ± 27.8 (P = 0.058). The mortality rate was 17.9% for GI, 33.3% for GII and 73.3% for GIII (P = 0.01). The association between positive changes and mortality was 30.8% for GI, and 100% for GII and GIII (P = 0.01).

Conclusions
We conclude that positive changes in the CDI during the MV are associated with mortality due to ARF. The CDI may help to improve the MV settings according to the patient’s response to the FiO2, and PEEP treatment.

Flow-balanced expiration reduces oedema formation in a porcine oleic acid lung injury model
S Schumann1, U Goebell2, J Haberstroh3, M Schneider1, HJ Priebe1, M Lichtwarck-Aschoff1, J Guttmann1
1University Medical Center, Freiburg, Germany; 2University BioMed Center, Freiburg, Germany; 3Uppsala University, Uppsala, Sweden

Introduction
Positive pressure ventilation involves ventilator-controlled inflation of the lungs followed by passive expiration driven by the elastic recoil forces of the respiratory system. In contrast to inspiration where the flow is controlled by the ventilator, expiration is passive, and the only clinically available means of influencing expiration is positive-end-expiratory pressure (PEEP). During passive expiration, the flow curve starts with a high peak flow followed by an exponential decay in airflow rate so that typically there is no flow during more than 50% of expiration time. Prolonging the phase of expiratory flow may be expected to be lung protective.

Methods
Sixteen pigs with oleic acid-induced lung injury were mechanically ventilated for 6 hours with volume-controlled ventilation either without or with flow-balanced expiration. Following insertion of a controllable expiratory resistance into the expiratory outlet of the ventilator, expiratory resistance markedly increased at the beginning of expiration and decreased continuously during the expiration phase. As a result, the expiratory flow curve changed from an exponentially decaying curve to a balanced flow pattern with lower flow rates at the beginning and higher ones at the end of the expiration phase, thereby achieving complete expiration. Ventilation settings were tidal volume 8 ml/kg, I:E ratio 1:2, RR 15/min, Ti/exp 1.5 s. Initially PEEP was set at 8 cmH2O. During the experiment, PEEP was adjusted to maintain PaO2 ≥60 mmHg.

Results
To maintain PaO2 ≥60 mmHg, after 6 hours of mechanical ventilation PEEP had to be increased from 8 to 13 ± 3 cmH2O in the conventionally ventilated animals but to only to 10 ± 1 cmH2O in the animals ventilated with flow-balanced expiration (P < 0.05). Lung biopsies from animals ventilated without flow-balanced expiration showed more infiltrations and thicker septa compared with those ventilated with flow-balanced expiration (all P < 0.05). The wet-to-dry ratio of tissue samples from lungs ventilated with without flow-balanced expiration were higher than those from lungs ventilated with flow-balanced expiration (10 ± 5 vs. 5 ± 4, P < 0.05).

Conclusions
Flow-balanced expiration during mechanical ventilation reduces oedema formation in the injured lung. Reduced expiratory peak flow and increased mean airway pressure during expiration are likely to have contributed to this beneficial effect.

Introduction

Unphysiological lung strain (tidal volume/functional residual capacity, TV/FRC) may cause ventilator-induced lung injury (VILI) [1]. Whether VILI develops proportionally to the applied strain or only above a critical threshold remains unknown.

Methods

In 20 healthy, mechanically ventilated pigs, FRC and lung weight were measured by computed tomography. Animals were then ventilated for up to 54 hours with a TV set to produce a predetermined strain. At the end, lung weight was measured with a balance. VILI was defined as final lung weight exceeding the initial one.

Results

Lung weight either did not increase at all (no-VILI group; lung weight change –73 ± 42 g, n = 9) or markedly augmented (VILI group; 264 ± 80 g, n = 11). In the two groups, strain was 1.38 ± 0.68 and 2.16 ± 0.50 (P < 0.01), respectively. VILI occurred only when lung strain reached or exceeded a critical threshold, between 1.5 and 2.1 (Figure 1).

Conclusions

In animals with healthy lungs VILI only occurs when lung strain exceeds a critical threshold.

Critical Care 2011, Volume 15 Suppl 1

Introduction Increased respiratory pattern variability is associated with improved oxygenation. Pressure support (PS) is a widely used partial-assist mechanical ventilation (MV) mode, in which each breathing cycle is initiated by flow or pressure variation at the airway due to patient inspiratory effort. Neurally adjusted ventilatory assist (NAVA) is relatively new and uses the electrical activity of the diaphragm (Eadi) to deliver ventilatory support proportional to the patient’s inspiratory demand. We hypothesize that respiratory variability should be greater with NAVA compared with PS.

Methods Twenty-two patients underwent 20 minutes of PS followed by 20 minutes of NAVA. Flow and Eadi curves were used to obtain tidal volume (Vt) and Eadi for 300 to 400 breaths in each patient. Patient-specific cumulative distribution functions (CDF) show the probability Vt and Eadi within a clinically defined (±10%) variability band for each patient. Values are normalized to patient-specific medians for direct comparison. Variability in Vt (outcome) is thus expressed in terms of variability in Eadi (demand) on the same plot.

Results Variability in Vt relative to variability in Eadi is significantly greater for NAVA than PS (P = 0.00012). Hence, greater variability in outcome Vt is obtained for a given demand in Eadi, under NAVA, as illustrated in Figure 1 for a typical patient. A Fisher 2 x 2 contingency analysis showed that 45% of patients under NAVA had a Vt variability in equal proportion to Eadi variability, versus 0% for PS (P < 0.05).

Conclusions NAVA yields greater variability in tidal volume, relative to Eadi demand, and a better match between Vt and Eadi. These results indicate that NAVA could achieve improved oxygenation compared with PS when sufficient underlying variability in Eadi is present, due to its ability to achieve higher tidal volume variability from a given variability in Eadi.

P202
Suspended animation-inducer hydrogen sulphide protects against organ injury during endotoxemia, but aggravates systemic inflammation

H Aslami, C Beurskens, F De Beer, M Kuipers, M Schultz, N Juffermans

Academic Medical Centre, Amsterdam, the Netherlands

Critical Care 2011, Volume 15 Suppl 1

Introduction A suspended animation-like state induced by hydrogen sulphide (H₂S) was shown before to protect lungs from ventilator-induced lung injury by reducing metabolism and inflammation. This beneficial effect of H₂S seems promising, but the effects of H₂S during prolonged infusion are unknown. We hypothesized that reducing metabolism in a rat model of LPS-induced systemic inflammation during 8 hours is more protective than during 4 hours.

Methods After anesthesia, rats (400 g) received an intravenous injection with 7.5 ml/kg LPS and were subsequently randomized to 4 or 8 hours of PEEP mechanical ventilation and treated with intravenous H₂S donor NaHS (2 mg/kg/hour). Controls received saline. During the experiment, mean arterial pressure (MAP) was kept above 65 mmHg with fluids and noradrenalin infusion. After exsanguination, bronchoalveolar lavage fluid was obtained and organs were harvested. Data are mean ± SEM.

Results H₂S reduced metabolism, exemplified by a reduction in heart rate, body temperature and etCO₂ compared with saline controls. Also, oxygenation was improved in these groups. The H₂S-treated animals required more noradrenalin to keep the MAP above 65 mmHg. LPS-induced lung injury was reduced after 4 hours of H₂S infusion compared with controls, with lower BALF protein levels (399 ± 46 vs. 655 ± 85 μg/ml), IL-6 levels (4.5 ± 0.3 vs. 6.2 ± 0.6 ng/ml) and CINC3 levels (2.4 ± 0.09 vs. 2.9 ± 0.2 ng/ml) (P < 0.05 for all), whereas 8 hours of infusion did not enhance protection. Kidney injury, measured by wet-to-dry ratio, was reduced after 8 hours of H₂S infusion compared with saline controls (5.5 ± 0.1 vs. 6.1 ± 0.1 ratio, P < 0.05). The cumulative fluid balance was the same in all groups. In contrast to the protective effect at tissue level, H₂S infusion resulted in enhanced systemic levels of IL-1, IL-6, TNF and CINC3 compared with saline controls.

Conclusions During endotoxemia, 4 hours of H₂S infusion protected against lung injury, which was not further enhanced by 8 hours of infusion. In contrast, kidney damage was diminished after 8 hours but not after 4 hours of H₂S infusion. However, H₂S aggravated systemic inflammation in endotoxemia, suggesting that administration of H₂S gas may be preferable.

Dead space fraction indicates the titration of optimal positive end-expiratory pressure after recruitment in acute respiratory distress syndrome

Y Yang, J Chen, HR Qi

Zhong-Da Hospital and College of Southeast University, Nanjing, China

Critical Care 2011, Volume 15 Suppl 1

Introduction The objective of this study is to evaluate the value of dead space fraction (VD/VT) as a method for indicating the optimal PEEP titration.

Methods Twenty-three patients with ARDS were enrolled in the study. After lung recruitment using sustained inflation (SI), the optimal PEEP was respectively titrated by the optimal oxygenation, the maximum static pulmonary compliance (Cst), and the lowest VD/VT. The influence of these methods on oxygenation, Cst, VD/VT and FRC were observed.

Results The PEEP level titrated by the lowest VD/VT (10.1 ± 2.8 cmH₂O) had no significant difference from the lowest PEEP level titrated by the maximum Cst (11.3 ± 2.5 cmH₂O) (P > 0.05). However, the PEEP level titrated by the lowest VD/VT was significantly lower than that determined by optimal oxygenation (P < 0.05). The oxygenation at the PEEP titrated by VD/VT was significantly lower than the optimal oxygenation, but no significant difference in PaO₂/FiO₂ was observed.
between the PEEP titrated by the lowest VD/VT and the maximum Cst. Additionally, the VD/VT and the FRC at the PEEP chosen by the three methods also had no significant difference.

**Conclusions** The lowest VD/VT could be one of the methods to choose the optimal PEEP in ARDS patients.

Dynamic distribution of conventional dendritic cells in the lung, blood and spleen from the early phase of sepsis-induced acute lung injury

J Liu, H Qiu
Zhong-Da Hospital, Southeast University, Nanjing, China

**Introduction** Respiratory dendritic cells (DCs), especially conventional DCs, are centrally involved in the induction phase of the immune response in our respiratory system. However, their role in acute lung injury (ALI) is largely unknown and little information concerning cDCs response in our respiratory system. However, their role in acute lung injury (ALI) is largely unknown and little information concerning cDCs of blood and spleen is available on ALI.

**Methods** C57BL/6 mice were intratracheally challenged with *Escherichia coli* LPS (2 mg/kg). At 6 hours, 12 hours, and 24 hours after i.t. delivery of LPS (ALI group) or PBS alone (Control group), mice were sacrificed, and blood, lungs and spleens were collected. cDCs were detected using flow cytometry in enzyme-digested lung, blood, and spleen.

**Results** The sepsis-induced ALI showed divergent kinetics of cDCs in peripheral blood, lung and spleen, respectively. ALI resulted in a rapid cDC accumulation in the lung, the frequencies of cDCs in ALI mice were significantly increased during all time points, compromised (2.38 ± 0.78)% at 12 hours, and peaked at 24 hours postchallenge (2.86 ± 0.55%), relative to lung nucleated cells (P < 0.05 vs. Control). However, splenic cDCs only showed a markedly transient augmentation to a peak (1.92 ± 0.25)% at 12 hours (P < 0.05 vs. Control), but subsequently declined to baseline (0.96 ± 0.21)% at 24 hours. In contrast to the lung cDC accumulation at 6 hours, sepsis-induced ALI led to a decreased percentage (0.32 ± 0.10)% of circulating cDCs at the same time point (P < 0.05 vs. Control), then the percentage of circulating cDCs was significantly increased (1.50 ± 0.31)% compared with that of control mice at 12 hours, and further increased (2.20 ± 0.92)% at 24 hours after LPS-induced ALI (P < 0.05 vs. Control). All cDCs within the blood, lungs and spleens had undergone a modest maturation in ALI from sepsis.

**Conclusions** ALI by sepsis produces different quantitative and phenotypical changes in pulmonary, circulatory and splenic cDCs. Lung cDCs may participate in the early inflammatory response to ALI.

A radiological scale to predict the potentially recruitable lung in ALI/ARDS patients

D Chiumento1, M Cressoni1, A Marino2, E Gallazzi2, M Brionio2, MC Andrisani1, M Lazzerini1, P Biondetti1
1 Fondazione IRCCS Ca’ Granda-Ospedale Maggiore Policlinico, Milan, Italy; 2 Università degli Studi di Milano, Milan, Italy

**Introduction** In ALI/ARDS patients the amount of potentially recruitable lung is extremely variable and it is poorly predictable by the changes of oxygenation, carbon dioxide or compliance during a PEEP trial [1]. At the present time the gold standard to compute the lung recruitability is the quantitative lung CT scan, in which each lung image, after being manually drawn, is analyzed by dedicated software. However, this is both a laborious and time-consuming technique. The aim of this study was to evaluate the ability of a visual radiological scale compared with lung CT scan analysis to predict the lung recruitability in ALI/ARDS patients.

**Methods** A whole lung CT scan was performed at 5 and 45 cmH2O airway pressure. For CT scan analysis each lung image was manually outlined and analyzed by a dedicated software. The potentially recruitable lung was defined as the proportion of the nonaerated lung tissue in which aeration was restored [1]. For radiological visual scale analysis, two radiologists performed a blinded evaluation of the consolidation/collapsed areas in each lobe by visual inspection [2]. The overall lung change in consolidation/collapsed was obtained by the sum of each lobe and computed as the difference between the two conditions.

**Results** Twenty-four ALI/ARDS patients (age 59 ± 15 years, BMI 26 ± 4 kg/m2, PaO2/FiO2 170 ± 60, PEEP 10 ± 2 cmH2O) were enrolled. The percentage of potentially recruitable lung was 16.2 ± 7.1% and 14.7 ± 7.0%, computed by CT scan and by the visual radiological scale, respectively. The mean difference between CT scan analysis and visual radiological analysis was 3.3 ± 4.6% (median: 2.91, interquartile range: 0.38 to 6.56). The error of the visual method was lower than 5% in 14 patients (58.3%), between 5% and 10% in eight patients (33.3%) and between 10% and 15% in two patients (8.3%).

**Conclusions** The application of a radiological visual scale is able to predict the amount of potentially recruitable lung similarly to those obtained by a dedicated software avoiding the need of manually drawing each lung image.

**Thrombopoietin may enhance ventilator-induced lung injury**

LD Del Sorbo, V Fanelli, G Muraca, EL Martin, L Lutni, A Costamagna, B Assenzo, E Lupia, G Montrucchio, VM Randieri

University of Turin, Italy

**Introduction**

Ventilator-induced lung injury is characterized by release of inflammatory mediators and increased vascular permeability resulting in alveolar edema formation. Thrombopoietin (TPO), whose most known function is the stimulation of the proliferation of megakaryocytes, has also shown several proinflammatory effects. Moreover, TPO receptor, c-Mpl, is constitutively expressed on endothelial cells and may modulate the permeability of the endothelium. We investigated the role of TPO in the impairment of the alveolar-capillary membrane resulting in alveolar edema formation during mechanical ventilation.

**Methods**

An ex vivo model of isolated, ventilated and perfused mouse lung was set up: ventilation was performed for 2 hours with both low-stress pressure (peak inspiratory pressure = 7 cmH$_2$O, PEEP = 2 cmH$_2$O, RR = 90 beats/minute) and high-stress pressure (peak inspiratory pressure = 20 cmH$_2$O, PEEP = 0, RR = 90 beats/minute), in the presence or absence of TPO (1 ng/ml) in the perfusate (2% bovine serum albumin RPMI medium at 1 ml/minute flow rate). At the end of the experiment, lung compliance, assessed through tidal volume, and protein concentration in the bronchoalveolar lavage (BAL) fluid were measured.

**Results**

During high-stress ventilation, lung compliance was significantly reduced by the presence of TPO in both pressure setup, but the increase was statistically significant only after high-stress ventilation. See Table 1.

**Conclusions**

TPO may enhance the permeability of the alveolar-capillary membrane contributing to the mechanisms of ventilator-induced lung injury.

**Indoleamine-2,3-dioxygenase activity induces neutrophil apoptosis**

K Van der Sluijs, R Singh, A Dijkhuis, M Snoek, R Lutter

Academic Medical Center, Amsterdam, the Netherlands

**Introduction**

Influenza-related mortality is often caused by secondary bacterial pneumonia. We have previously shown that the tryptophan-catabolizing enzyme indoleamine-2,3-dioxygenase (IDO) critically impairs host defense against secondary bacterial pneumonia [1]. Since inhibition of IDO resulted in increased neutrophil numbers during primary viral infection, we hypothesized that tryptophan degradation and/or the generation of downstream metabolites induces neutrophil apoptosis. In the present study we aimed to investigate the impact of IDO-mediated tryptophan metabolism on neutrophil apoptosis in vitro and in vivo.

**Methods**

Freshly isolated neutrophils were cultured in the presence or absence of tryptophan, kynurenine and 3-hydroxy-anthranilic acid. Apoptosis was identified by annexin V/propidium iodine staining (%, mean ± SD). To confirm our *in vitro* data, transgenic mice that conditionally express IDO in the airway epithelium upon doxycycline (dox) treatment and control mice were challenged with LPS (1 μg) or Klebsiella pneumoniae (10$^8$ colony-forming units) intranasally and sacrificed after 24 hours to count neutrophils in bronchoalveolar lavage fluid (total number, mean ± SD). Statistical analysis was performed by Student’s t test or Mann–Whitney U test where appropriate. P < 0.05 was considered significant.

**Results**

Both kynurenine and 3-hydroxy-anthranilic acid enhanced apoptosis in freshly isolated neutrophils (60.3 ± 8.7% and 45.5 ± 1.7% respectively vs. 33.5 ± 8.1% under control conditions, both P < 0.05), which was reversed by adding tryptophan. Conditional transgenic mice, which showed marked expression of IDO in the pulmonary compartment, had reduced neutrophil numbers in bronchoalveolar lavage fluid after challenge with *K. pneumoniae* (3.36 ± 1.92 x 10$^5$ vs. 12.1 ± 9.0 x 10$^5$ in dox-treated littermates, P < 0.05) and LPS (1.88 ± 1.22 x 10$^5$ vs. 5.21 ± 3.81 x 10$^5$ in control-treated transgenic mice, P < 0.05), which was associated with active caspase-3 staining in dox-treated mice, but not in control mice.

**Conclusions**

Neutrophils undergo apoptosis in presence of kynurenine or 3-hydroxy-anthranilic acid and the absence of tryptophan. Pulmonary IDO expression, as occurs during influenza infection, enhances neutrophil apoptosis in vivo and may impair host defense against secondary bacterial infections.

or more SIRS criteria varied from 79.2% in the first 2 hours of admission compared with 70.2% 12 to 24 hours after admission. **Conclusions** The measured incidence of SIRS and sepsis heavily depended on minor variations in modes of data recording and interpretation of diagnostic criteria. A more precise definition of sepsis should be incorporated into the design of future clinical trials in sepsis in order to ensure the uniform recruitment of patients. **References**

Analysis of nosocomial bacteremia in an ICU during 16 months

L Cachafeiro, C Sonajo, J Figueria, J Manzanares, J Camacho, M. Jimenez Lendinez

Hospital la Paz, Spain  

**Introduction** The aim of our study is to evaluate the mortality, clinical impact and causative microorganisms of nosocomial bacteremia in the ICU of a tertiary university hospital.  

**Methods** A prospective observational study in a 20-bed medical/surgical ICU, during a 16-month period. We included all patients admitted to the ICU >24 hours, excluding patients with acute coronary disease, from February 2009 to June 2010. We collected all episodes of bacteremia occurring in patients, demographics and epidemiological data, clinical impact, overall hospital mortality, ICU mortality and mortality related to bacteremia. Bacteremia type (primary, secondary, or connected to the catheter), microbiologic agents and empirical antibiotic therapy used.  

**Results** A total of 1,112 patients were admitted to the ICU from February 2009 to June 2010. During this period, 63 nosocomial bacteremias were diagnosed in 45 patients, which represented 4% from the total admissions. The median age was 52 ± 16. Sixty-four percent were male. The median APACHE II score was 24 ± 9 versus 16 from the total admissions. The median age was 52 ± 16. Sixty-four percent were male. The median APACHE II score was 24 ± 9 versus 16.

**Conclusions** Nosocomial bloodstream infections in the ICU make a major impact, with a high percentage of patients with septic shock, high morbi-mortality and hospital stay. Multidrug-resistant microorganisms played an important role in these results. It is necessary to optimize the control measures of the RBC and other devices, minimizing the impact and causative microorganisms of nosocomial bacteremia in the ICU.

Delayed ICU admission with community-acquired severe sepsis greatly increases mortality and resource use

A Shorr1, Y Choe2, W Linde-Zwirble1

Washington Hospital Center, Washington, DC, USA; 1Eisai Inc, Woodcliff Lake, NJ, USA; 2ZD Associates LLC, Perkasie, PA, USA

**Introduction** While many severe sepsis (SS) patients go to the ICU on hospital admission, others with community-acquired infection (CAI) either progress to SS later in the hospitalization or are not considered severely ill on admission. The proportion of SS cases falling into these two groups is not known, and their outcomes are not well described.  

**Methods** We identified all adult hospitalizations in the 2008 Premier database that had an ICD-9-CM code for SS (995.92, 785.52), a CAI, and who entered the hospital through the ED (for example, not transferred from another hospital). Patients were characterized by the sequence of ICU and floor care, the number of antibiotic classes (AbxC) on day 1, and the duration of floor stay before ICU admission. We assessed resource use via length of stay (LOS) and total cost. We also examined hospital mortality.  

**Results** The cohort included 33,059 discharges (49.1% male, mean age 69.0 years), of whom 17,690 (53.5%) were admitted to the ICU at hospital presentation. Mortality in direct to ICU subjects equaled 31.2%, and these patients had an average LOS of 12.0 days with a mean cost of $30,174, with only 22.8% given a single AbxC. Those admitted to the floor initially (46.5%) had a similar LOS (11.7 days) and mortality (31.1%) but had lower mean costs ($22,728) and nearly half (49.3%) had a single AbxC. Of these initial floor patients, those that were never admitted to the ICU (28.0% of all cases) had the shortest stay (7.6 days), lowest cost ($11,753), and lowest mortality (24.2%) with 44.3% receiving a single AbxC on day 1. Those starting on the floor and later transferred to the ICU (18.4% of all cases) had the longest stay (17.7 days), highest cost ($39,332) and highest mortality (41.5%), and were most likely to have a single AbxC on day 1 (56.8%). Even those admitted to the ICU after 1 day on the floor (3,179, 52.1% of delayed ICU cases) had higher mortality (36.0%) than those starting in the ICU (P <0.0001). Mortality increased with longer delays before ICU admission (40.7%, for a 2-day delay (14.1% of delayed cases) and 50.3% for those with a 3-day or more delay (33.8% of delay cases)).  

**Conclusions** SS patients with CAI admitted to the floor and later transferred to the ICU are a major fraction of all SS cases and have the worst outcomes. While many may have developed organ dysfunctions earlier in the hospitalization, nearly two-thirds were admitted to the ICU after just 1 or 2 days on the ward, indicating that they may have been mis-triaged. Interventions to better identify and aggressively treat these cases may improve outcomes.

Septic shock in a cohort of patients from the northeast of France: a preliminary epidemiological study, EPISS group

J Quenot1, A Pavon1, C Binquet2, F Kara, O Martinet3, JC Navellou4, D Barraud5, J Cousson6, JP Poussielgue7

1University hospital Bocage, Dijon, France; 2Faculté de Médecine, Dijon, France; 3Centre Hospitalier, Haguenau, France; 4Nouvel Hôpital Civil, Strasbourg, France; 5Centre Hospitalier Universitaire, Besancon, France; 6Hôpital Central, Nancy, France; 7Centre Hospitalier, Intensive Care, Reims, France  

**Introduction** Incidence of septic shock in France ranges from 8 to 10% among patients admitted to intensive care. Mortality at 28 days is 55 to 60% [1]. We aimed to investigate epidemiology, treatment and mortality of patients with septic shock further to the Surviving Sepsis Campaign international guidelines [2].  

**Methods** A prospective, multicentre, observational cohort study supported by the Collège Intergénéral des Réanimateurs du Nord-Est (CIRNE) including 14 ICUs in 10 university or nonacademic hospitals. Inclusion criteria were: patients presenting with documented/suspected infection requiring initiation of vasopressor amines despite adequate vascular filling, with at least one of the following hyperperfusion criteria: metabolic acidosis (base excess ≥5 mEq/l or alkaline reserve <18 mEq/l or lactate ≥2.5 mmol/l); oliguria/renal insufficiency (<0.5 ml/kg/hour for 3 hours or elevation >50% of baseline creatinine); or hepatic dysfunction (AST or ALT >500 IU/l or bilirubin >20 mg/dl (34 μmol/l)). Quality control was performed by the Dijon Clinical Investigation Center (INSERM).  

**Results** Mean inclusion was 80 patients/month for all centres. We analysed the first 350 patients with validated files of 876 patients included up to 1 December 2010. Mean age was 69 ± 13 years, 66% men. Indication for admission was medical in 84%. Mean SAPS II score was 60.9 ± 21.8, mean SOFA score at time of shock was 11.7 ± 3.5. Sepsis
was mainly of pulmonary (45.7%), digestive (19.4%), or urinary (11.1%) origin, with 23.8% other causes. Sepsis was mainly community-acquired (63.7%) and was documented in 67% (234/350), of which 53.4% were Gram-negative bacilli, 30.3% Gram-positive cocci and 16.3% others. Replacement techniques used were: invasive mechanical ventilation (82.6%), continuous dialysis (31.1%) and discontinuous dialysis (19.7%). Activated protein C was used in 17 patients (5%) and hydrocortisone hemisuccinate in 238 (68.6%). Mortality was 49.1% in intensive care, 58.8% in hospital.

Conclusions Our findings raise hope of improved knowledge of epidemiology and management of septic shock in intensive care patients, and should have a beneficial effect on prognosis.

Long-term effects of an in-hospital program on sepsis management in the ICU
E Ferrari1, G Serafini1, D Trevisan1, L Donno2, L Rinaldi2, M Girardis1
1Università degli Studi di Modena e Reggio Emilia, Modena, Italy; 2Policlinico di Modena, Italy

Introduction A hospital program named Sopravvivere alla Sepsi nel Policlinico di Modena (www.policlinico.mo.it) started in 2005 with the main objective to improve the survival rate of septic patients by means of continuous education and implementation of a sepsis operative protocol including the activation of a specific consultation by an intensivist and an infectious disease specialist. The aim of this study was to evaluate the long-term effects of this in-hospital program on compliance to treatments indicated by the evidence-based guidelines and on outcome in patients admitted to the ICU with septic shock (SS).

Methods In patients admitted with SS to a 10-bed ICU from January 2005 to December 2009 we collected: age, type of admission (medical or surgical), site of infection, SAPS II, 30-day mortality and the application of five resuscitative (blood cultures before antibiotics, antibiotics within 3 hours, source control, adequate fluid resuscitation, \(\text{SvO}_2\) optimization within 6 hours) and four management interventions (glycemia control, steroid use, rAPC administration and plateau inspiratory pressure \(<30\text{ cmH}_2\text{O}\)) as suggested by the surviving sepsis guidelines. Patients with end-stage liver disease, age <18 years and indications for end-of-life treatment were excluded.

Results A total of 129 patients have been evaluated and the number of SS admissions increased from a mean value of 19 patients/year in the period 2005 to 2007 to a value of 36 patients/year in the past 2 years. Age, SAPS II and site of infection were similar throughout the analyzed period whereas the percentage of medical admission increased from 33% to 42% in the past 2 years. Compliance to the five resuscitative interventions improved progressively from 24% in 2005 to 42% in 2007. Subsequently, they came back to values observed at the starting of the project (21% in 2008 and 25% in 2009). Similarly, the adherence to management interventions increased quickly after 2005 (from 14% to 50% in 2006) but decreased to a mean value of 35% in the past 3 years. Immediately after 2005, the observed 30-day mortality rate became lower than that predicted by the SAPS II, but it slightly increased from 31% in 2006 to 48% in 2009.

Conclusions The effects of an in-hospital program devoted to severe sepsis and SS management allowed an increase of ICU admissions for sepsis, a better management and an improvement of patients’ survival rate. However, as expected, the adherence to guidelines gradually worsened with a slight increased in mortality rate in the past 2 years.

Extending the classification of healthcare-associated bloodstream infection to other main foci: respiratory, urinary and intra-abdominal
C Cardoso1, O Ribeiro2, I Aragão1, A Costa-Pereira2, A Sarmento1
1Hospital de Santo António, Porto, Portugal; 2Faculty of Medicine, University of Porto, Portugal; 3Hospital de São João, Porto, Portugal

Introduction Healthcare-associated infection (HCAI) is a growing phenomena associated with the increase of the outpatient clinical

Figure 1 (abstract P214). Microbiological profile according to the focus of infection.
care. Friedman in 2002 proposed a new classification for healthcare-associated bloodstream infections, suggesting that they are different from nosocomial and community-acquired infections [1]. The authors extend this classification to other main focus of infection: respiratory, urinary and intra-abdominal.

**Methods** A prospective cohort study (1 year), in five wards of a university hospital, including all consecutive adult patients that met the CDC definition of infection. Only the first episode of infection was characterized. They were classified in community-acquired (CAI), HCAI (using Friedman’s classification [1]) and hospital-acquired (HAI), and data on the host and the infectious episode were collected.

**Results** See Figure 1. We included 1,035 patients: 493 (48%) with CAI, 225 (22%) with HCAI and 317 (31%) with HAI.

**Conclusions** Differences were observed according to the type and focus of infection. These results reinforce the need for this classification and probably the need for specific antibiotic therapy guidelines for this group of patients.

**P215 Healthcare-associated infection: do doctors recognize this group of patients?**

T Cardoso1, O Ribeiro2, I Aragão1, A Costa-Pereira1, S Sarmento1

1Hospital de Santo António, Porto, Portugal; 2Faculty of Medicine, University of Porto, Portugal

**Introduction** Traditionally infections are divided into community acquired (CAI) or hospital acquired (HAI). The authors study the association between healthcare-associated infections (HCAI) and inappropriate antibiotic therapy and hospital mortality.

**Methods** A prospective cohort study (1 year), in five wards of a university hospital, including all consecutive adult patients that met the CDC definition of infection. They were classified in: CAI, HCAI (using Friedman’s classification [1]) and HAI. A multivariable logistic regression was used with inappropriate antibiotic therapy as the dependent variable and sex, age, previous co-morbidities, type of infection (CAI, HCAI or HAI), severity of infection, SAPS II, total SOFA score, focus of infection, polymicrobial infection, previous antibiotic therapy, positive blood cultures, number of hospitalizations in the previous year and Karnovsky index as independent variables, and a similar model with also inappropriate antibiotic therapy and microbiological diagnosis with hospital mortality as the dependent variable.

**Results** We included 1,035 patients: 493 (48%) with CAI, 225 (22%) with HCAI and 317 (31%) with HAI. HCAI (adjusted OR = 1.905, 95% CI = 1.152 to 3.138) was associated with inappropriate antibiotic therapy. The following variables were associated with hospital mortality: HAI (adjusted OR = 2.095, 95% CI = 1.275 to 3.441), cancer (adjusted OR = 2.768, 95% CI = 1.316 to 5.823), diabetes (adjusted OR = 0.420, 95% CI = 0.228 to 0.775), Karnovsky index (adjusted OR = 0.968, 95% CI = 0.950 to 0.987), SAPS II (adjusted OR = 1.107, 95% CI = 1.085 to 1.128) and inappropriate antibiotic therapy (adjusted OR = 1.663, 95% CI = 1.006 to 2.747). HCAI was not associated with increased hospital mortality (adjusted OR = 0.808, 95% CI = 0.449 to 1.453), although this group of patients had higher SAPS II (median = 30 vs. 28 in the other two groups, P = 0.002), no differences were found regarding median SOFA score or severity of infection.

**Conclusions** HCAI was not associated with increased hospital mortality but it was associated with inappropriate antibiotic therapy, an independent prognostic factor. Doctors might not be sufficiently aware of this new group of patients. Locally driven information campaigns are needed.

**P216 Sustainability of an antimicrobial stewardship program in a community hospital ICU at 3 months post implementation**

K Walker, J Sauve, J Powis, V Leung, S Gill

Toronto East General Hospital, Toronto, Canada

**Introduction** Our goal was to develop an antimicrobial stewardship program (ASP) and integrate it within a medical/surgical ICU clinical practice. During a 3-month pilot ASP, one pharmacist (Ph) provided clinical service and one antimicrobial (AM) stewardship pharmacist (ASPh) participated in the ICU ASP. Two ASP Phs worked routines as designated ICU Phms. Post ASP implementation, the ICU Ph added AM stewardship to their role.

**Methods** From 1 April to 30 June 2010, a pilot ASP was implemented in a 490-bed urban community hospital ICU on weekdays. The pilot ASP goals were to optimize/reduce AM usage, improve clinical outcomes and reduce nosocomial *C. difficile* infections rates [1]. The Phms collected information on ICU patients receiving AM on a standardized data collection tool. Identified patients were reviewed with the infectious disease (ID) physician, then the ASPPh and ID physician met with the ICU care team to discuss ways to optimize AM use. After the pilot ASP, this process was reduced to 3 weekdays and conducted by the ICU Ph, eliminating the ASP Ph involvement. The same metrics used in the pilot program were collected for a 3-month follow-up period [2].

**Results** The pilot ASP resulted in a 47.7% reduction in AM cost from $58,544 (1 April to 30 Jun 2009) to $30,627 (1 April to 30 June 2010). The AM cost in the 3-month post-ASP period (1 July to 30 September 2010) was $22,010. No new cases of nosocomial *C. difficile* infections were identified during the pilot period. Based on an average of 1.4 cases/1,000 patient-days, two cases were expected during the pilot period. The post-pilot period observed 0.42 cases/1,000 patient-days. The pilot ASP showed a 38.9% reduction of broad-spectrum anti-pseudomonal AM usage as compared with the same time period of the previous year and a 28.5% reduction in the 3-month post-ASP period. No changes were noted in the Multiple Organ Dysfunction Score or mortality in the pilot and post-pilot groups as compared with the same time period of the previous year.

**Conclusions** The ICU Ph developed the skills required through participation in the pilot ASP program and integrated it within their daily ICU practice. The post-ASP period showed sustained reductions in AM use, costs and nosocomial *C. difficile* rates.

**P217 Attention to electronic prescription process improves time to first-dose antibiotics in patients on the ICU**

R Wan1, D Gonzalez Bermejoi, S Moore3, C Whiteley1, C Mckenzie1, A Jones1

1Guy’s & St Thomas’ NHS Foundation Trust, London, UK; 2La Paz University Hospital, Madrid, Spain; 3Kings College Medical School, London, UK

**Introduction** Effective timely antibiotic administration is associated with increased survival to discharge in patients with septic shock [1]. Time to antibiotic administration was the strongest predictor of outcome and is a key recommendation in sepsis management [2]. However, implementation faces barriers at clinician, patient and environmental levels [3].

**Methods** A retrospective review of antibiotic prescribing on a 30-bed university medical–surgical ICU. Data were extracted from the clinical informatics system (Intellivue Clinical Portfolio (ICP) Philips). For a 4-month period (baseline assessment September 2009 to January 2010), patients initiated on new intravenous antibiotics were included. After baseline data review, the ICP prescription order process was modified to automatically include STAT doses. A further 4-month period (post implementation) review followed.
Results At baseline, 139 patients and 320 prescriptions were analysed. Median time to antibiotic administration was 127 minutes (IQR 29 to 272). The proportion of antibiotics administered within 1 hour and 3 hours was found to be 81/320 (25%) and 193/320 (60%), respectively. Analysis by antibiotic class revealed aminoglycosides and vancomycin had the lowest median time that in our unit are initiated as STAT doses, 86 minutes (IQR 43 to 195 minutes). Post modification of the ICIP prescription order process, 139 patients and 194 prescriptions were analysed. Median time to antibiotic administration improved to 79 minutes (IQR 43 to 159), P < 0.001. A greater proportion was administered within 1 hour (70/194, 37%) and 3 hours (153/194, 79%), P < 0.001, for this cohort.

Conclusions Barriers to timely administration of antibiotics exist, an intervention shown to significantly improve patient outcome. This study demonstrates modification of an electronic prescribing order process contributes to improved performance. However, a multifactorial problem may exist. It confirms clinical informatics systems play in improving the delivery of quality patient care in the ICU.

An audit of antibiotic dosing according to renal function or renal replacement therapy in critical care
KD Donnelly, KD Smith, U Coleman, D Westwood, AN Billington
UHB Trust, Birmingham, UK

Introduction An audit of antibiotic dosing was conducted over the four critical care units at University Hospital Birmingham. The prescribed dose of four antibiotics (co-amoxiclav, meropenem, tazocin and ciprofloxacin) was audited against local prescribing guidance based on renal function and use of renal replacement therapy (RRT).

Methods The electronic prescribing system was interrogated for all prescriptions of the intravenous (i.v.) form of the antibiotics during 2009. Antibiotic, dose and frequency, estimated glomerular filtration rate (eGFR), and number of administrations were recorded. One-off prescriptions and those without recent eGFR were discarded. A total of 2,472 records were included. Prescriptions were grouped by unit and antibiotic, then by renal function (normal, mild, moderate or severe impairment) or RRT, and by one of four categories (appropriate, underdosing, overdosing or incorrect regimen).

Results Of the 2,472 prescriptions, 2,004 (81.1%) were correctly prescribed with regards to renal function and RRT. The total numbers of prescriptions per antibiotic are as follows: co-amoxiclav (631 prescriptions, of these 94.9% correct), ciprofloxacin (282, 98.9%), tazocin (696, 80.6%) and meropenem (863, 65.6%). On Unit 3, tazocin was underdosed in cases of normal renal function (15.2% of their ward’s prescriptions with regard to that antibiotic; median administrations 3, range 1 to 15), and during RRT (6.5%; 6, 0 to 29). On Unit 4, tazocin was underdosed during mild renal failure (7.0%; 9, 2 to 81) and during RRT (7.7%; 10, 3 to 30). Meropenem was overdosed during RRT on Unit 1 (6.1%; 4, 0 to 30), Unit 3 (20%, 15, 1 to 38) and Unit 4 (13%; 15, 1 to 31), and underdosed during RRT on Unit 4 (17.9%; 7.5, 1 to 28).

Conclusions Tazocin was frequently underdosed in this critically ill population. It is possible that the minimum inhibitory concentration was not reached in some patients, with the associated risk of treatment failure [1,2]. Meropenem was underdosed on one unit; however, overdosing was more common. The clinical significance of this is equivocal as raised peak levels can be advantageous [3]. The electronic prescribing system currently lacks renal dosing decision support; this audit suggests a potential benefit to the integration of antibiotic prescribing guidelines.

De-escalation of antimicrobial therapy in Gram-negative sepsis: easier said than done?
L Phee, N Gordon, M Horne5, D Wareham1
1Barts and The London NHS Trust, London, UK; 2QMUL, London, UK

Introduction Appropriate and timely de-escalation of antimicrobial therapy has long been recognised as an important element in the optimal management of sepsis. When a causative pathogen has been isolated and its susceptibility profile known, the most suitable single therapy should be instituted to prevent the development of super-infection with pathogenic or resistant organisms, as well as reduce toxicity and costs.

Methods All blood cultures analysed on the BD BACTEC system were evaluated over a 6-week period (17 April 2010 to 30 May 2010). Organisms in positive blood cultures were then further identified by MALDI-TOF mass spectrometry (Brucker) and susceptibility testing was performed using the MicroScan WalkAway system (Siemens). The demographics, treatment regimens and clinical outcomes of all episodes of clinically significant Gram-negative bacteraemia were prospectively audited.

Results Two hundred and seventy sets of blood cultures were positive during our study period, representing 246 individual bacteraemic episodes. A total 143/270 were considered contaminants, 42/270 were significant Gram-positive bacteraemias, 1/270 Candida albicans, and 84/270 Gram-negative bacteraemia. Of the latter, 70 were individual episodes, of which two died prior to susceptibility results being available. Of the survivors, following knowledge of the susceptibility profile, only 20.5% (14) were de-escalated to a narrower-spectrum agent and only 31% (21) were converted to suitable oral agents when practical. Twelve per cent (10) were treated with combination therapies even though single agents remained highly active. Of the group that failed to de-escalate antimicrobial therapy (54 patients), the 30-day mortality rate was 9% (5/54) versus 7% (1/14) in the group (14 patients) that adhered to the surviving sepsis guidelines. Likewise, the former group were more likely to develop diarrhoea, 38% (21/54) versus 21% (3/14), with three patients positive for Clostridium difficile in the former group (none in the latter). Multidrug-resistant organisms and fungal colonisation occurred more frequently in the first group – 38% (21/54) and 22% (12/54) versus 21% (3/14) and 0% (0/14), respectively.

Conclusions Surviving sepsis guidelines have reiterated the need for timely use of appropriate empirical antimicrobials as well as the importance of de-escalation of therapy when the causative agent has been identified. However, as is the case in our study, this has not always been the prevailing practice. Many factors underlie this deviation from recommended guidelines, including worsening clinical condition, reported penicillin allergy as well as multiple co-morbidities.

Impact of the adequacy of antibiotic therapy on the outcome of ventilator-associated pneumonia
J Goncalves-Pereira, T Sequeira, B Maya, T Cardoso, N Catorze
1Hospital Sao Francisco Xavier, Lisboa, Portugal; 2Hospital Sao Jose, Lisboa, Portugal; 3Hospital Sao Bernardo, Setubal, Portugal; 4Hospital Santo Antonio, Porto, Portugal; 5Centro Hospitalar Median Tejo, Abrantes, Portugal

Introduction The aim was to assess the impact of empiric antibiotic adequacy on ICU outcome of patients with ventilator-associated pneumonia (VAP), the reasons for inadequacy and risk factors for potential multidrug-resistant organisms.

Methods During a 24-month period a multiple-centre observational study was conducted in five ICUs. Adult patients with documented VAP were segregated for analysis. Empiric antibiotic therapy was classified as adequate or inadequate according to in vitro efficacy against all isolated bacteria. The day of ICU discharge or death was recorded. Comparison between survivors and nonsurvivors was performed. Infection with potential multidrug-resistant organisms

Aetiology of pneumonia in the ICU: the need for early Gram-negative cover
A Khanna1, H Al-Shater1, M Chawla1, R Gibbs1
Musgrove Park Hospital, Somerset, UK; 2Nottingham City Hospital, Nottingham, UK

Introduction Pneumonia remains one of the commonest infectious causes of intensive care unit (ICU) admissions. Despite recent advances, mortality in the ICU from this diagnosis remains around 50% [1]. Early targeted antibiotic therapy to minimise the development of ventilator-associated pneumonia is recommended [2]. This requires an updated knowledge of aetiology of this common diagnosis in ICU settings.

Methods We conducted a retrospective cohort study into 200 consecutive admissions to our ICU with coded diagnosis of pneumonia. Baseline patient characteristics microbiological diagnosis, disease severity and mortality outcomes were studied.

Results The average patient age in this cohort was 58 years (range 11 to 90 years). The male to female ratio was 1.35:1. All of the patients were admitted to ICU within 48 hours of their hospital admission, mainly due to worsening respiratory failure. Out of the total of 200 cases, microbiological isolates were identified in 110 (55%). Eighty-five isolates were deemed likely to be pathogenic (42.5%) while 25 (12.5%) were likely to be the result of antibiotic use (candida and coliforms species in sputum). Gram-negative bacteria were responsible for 50.9% isolates. Streptococcus pneumoniae remained the single most common isolate (28/110; 25.4%), Pseudomonas species (23/110; 20.9%) and Haemophilus influenzae (11/110; 10%) were the second and third most common isolates. Pseudomonas infection was more often associated with advanced age and existing lung pathology. Staphylococcus aureus was isolated in 8.1% (9/110) with one confirmed as methicillin resistant (MRSA). Atypical organisms (Legionella 2.7%, mycoplasma spp. 0.9%) and fastidious organisms (Sternothomonas maltophilina 2.7%) were also isolated. Other organisms isolated included enterobacter cloacae, Citrobacter koseri, Streptococcus Group A, Haemophilus parainfluenzae, Moraxella catarrhalis and Klebsiella species. Mortality amongst our patients was 28.5% (57/200). This was comparable with previously published findings.

Conclusions Whilst the aetiology of pneumonia in our cohort is similar to that previously reported [3], the incidence of Gram-negative organisms is much higher. This, if reconfirmed, may have important implications in designing targeted antibiotic therapy for pneumonia in ICU settings.

References
was higher in ARDS patients than in non-ARDS pneumonia (6.98 ± 2.25 vs. 3.86 ± 0.69, P = 0.002). The PCWP in ARDS patients was 16.08 ± 4.93 that was higher than in the non-ARDS group (11.82 ± 1.01), but no statistical significance was demonstrated. The ejection fraction (EF) was measured in 14 patients. The average EF was 59.79 ± 12.87%. There was only one patient having EF less than 30%. There was no statistical significance found in the EF between the ARDS and non-ARDS groups. The E/A ratio and E/E' were 1.29 ± 0.49 and 8.67 ± 2.25, respectively.

Conclusions The novel influenza A (H1N1) severe pneumonia resulted in high CO in the ARDS group. The PCWP in these patients was also higher than that in non-ARDS patients. Due to almost all patients having good left ventricular contraction, the etiology of higher PCWP in ARDS patients might result from some degree of high-output cardiac dysfunction. Thus diuretics may have an important role to improve impaired gas exchange in these patients caused by this severe viral pneumonia with ARDS.

P224 Gram-positive nosocomial infections in a general ICU: emerging new clues
S Milanov, G Georgiev, V Todorova, M Milanov
Pirogov Emergency Institute, Sofia, Bulgaria

Introduction Gram-positive aerobes are currently the leading cause of infection in many ICUs. Despite this trend, there are still no firm recommendations for empiric Gram-positive antimicrobial coverage in patients with severe nosocomial infections. The current study is an extension of our previous work in this field, aiming to challenge some of the earlier trends and to bring out new clues.

Methods A prospective observational study was conducted including all episodes of documented nosocomial infection in a general ICU for a 4-year period (2006 to 2009). Data on demographics, primary diagnosis, co-morbidity, number of indwelling devices, previous microbial isolates and current antibiotics were cross-tabulated according to the presence and type of Gram-positive pathogens. For the identified most likely risk factors, separate contingency tables were constructed and analyzed.

Results A total of 339 patients with Gram-positive isolates were identified (51.21% of 662). Gram-positive isolates were more prevalent in patients with obesity (1.27; CI = 1.08 to 1.47) and diabetes (1.28; CI = 1.03 to 1.53). The following independent risk factors for Gram-positive nosocomial infections (RR and 95% CI) were identified: MRSE-gunshot wound (4.18; 2.35 to 5.19), stab wound (4.01; 2.03 to 4.59), polytrauma (1.91; 1.47 to 2.46), previous isolation of both Acinetobacter spp. and Pseudomonas or Candida spp. (2.01; 1.38 to 2.72 and 2.72; 1.71 to 4.21), treatment with aminoglycoside or carbapenem (2.52; 1.59 to 3.42 and 1.37; 1.03 to 1.80); Enterococcus – billiary peritonitis (2.23; 1.27 to 3.73), acute necrotizing pancreatitis (6.68; 2.36 to 9.65), previous isolation of both Klebsiella and Candida spp. (6.02; 1.85 to 9.40), treatment with cefoperazone + sulbactam or third-generation cephalosporin (3.49; 2.18 to 5.34 and 1.87; 1.17 to 2.92); MRSA – clinical extension of our previous work in this field, aiming to challenge some recommendations for empiric Gram-positive antimicrobial coverage in many ICUs. Despite this trend, there are still no firm recommendations for empiric Gram-positive antimicrobial coverage in patients with severe nosocomial infections. The current study is an extension of our previous work in this field, aiming to challenge some of the earlier trends and to bring out new clues.

Conclusions New light was shed on the identification of associated risk factors for Gram-positive nosocomial infections in our ICU. Sufficient data were gathered to aid empirical antibiotic choice in such high-risk patients.
catheter, endotracheal tube, arterial catheter or nasoenteral tube and acute renal failure requiring dialysis were significant risk factors for bacteremia (all \( P < 0.05 \)). In multivariate analysis, the number of recent invasive procedures (OR, 4.17; 95% CI, 1.6 to 11.1; \( P = 0.001 \)) and previous administration of carbapenem (OR, 2.07; 95% CI, 1.47 to 2.91; \( P = 0.036 \)) were independently associated with MDR Aspp bacteremia.

**Conclusions** Our results suggest that the nosocomial occurrence of MDRAspp bacteremia in colonized patients is strongly related to the number of invasive procedures and may be favored by the selection pressure of previous carbapenem administration.

**P227**

**Blood cultures at central line insertion: a comparison with peripheral venipuncture**

S Stohl1, S Benenson2, S Sviri2, C Block2, C Sprung3, P Levin4

Children’s Hospital of Philadelphia, PA, USA; 2Hadassah Hebrew University Medical Center, Jerusalem, Israel

**Introduction** The objective was to compare contamination rates of blood cultures obtained at central line (CVC) insertion with cultures obtained at peripheral venipuncture or arterial line (AL) insertion. Contamination of blood cultures adds to cost, length of hospital stay, and unnecessary antibiotic administration. As most contaminants come from patients’ skin, obtaining blood cultures after skin disinfection and under strict sterile precautions during CVC insertion might reduce contamination rates.

**Methods** A retrospective analysis of all blood cultures taken in the general and medical ICUs of a tertiary academic hospital over 8 years. Positive blood cultures were categorized as growing contaminants (Bacillus species, Corynebacterium species, Propionibacterium species, non-pneumococcal \( \alpha \)-hemolytic Streptococci, and single-culture isolates of coagulase-negative Staphylococci), or true pathogens (all other results). Results of CVC insertion cultures were compared with peripheral venipuncture and AL insertion cultures.

**Results** A total of 17,384 blood cultures including 3,389 (19.5%) CVC, 1,844 (10.6%) AL and 12,151 (69.9%) peripheral cultures were analyzed. CVC insertion cultures were contaminated more frequently than AL or peripheral cultures (455/3,389 (13.4%) CVC, 103/1,844 (5.6%) AL, and 755/12,151 (6.2%) peripheral cultures, \( P < 0.001 \) CVC vs. peripheral and CVC vs. AL). However, true pathogens were found more frequently in CVC insertion cultures (445/3,389 (13.1%) CVC, 192/1,844 (10.4%) AL and 1,122/12,151 (9.2%) peripheral cultures, \( P < 0.001 \) CVC vs. peripheral and CVC vs. AL). The contamination and true positive rates for each source were almost identical in each ICU. Although there was a general decrease in culture contaminants over 8 years, the proportion of contaminants in CVCs remained approximately double that found in peripheral cultures at all time points.

**Conclusions** In complete contrast to the expected findings, and despite superior sterile precautions, cultures taken at CVC insertion had a higher contamination rate than either peripheral or AL blood cultures. This difference persisted in both isolated ICUs and in cultures obtained over 8 years. The higher contamination rate may be related to the increased skin and soft tissue manipulations performed during CVC insertion. The higher true positive rate in CVC insertion cultures may indicate that these cultures retain utility.

**Polyhexanide anti-infective coating of central venous catheters in prevention of catheter colonization and bloodstream infection: Study HC-G-H-0507**

I Krikava1, M Kolar2, B Garajova1, T Balik2, A Sevcikova1, J Pachl2, P Sevcik1, R Trubac3

1University Hospital Brno, Czech Republic; 2University Hospital Kralovske Vinohrady, Prague, Czech Republic; 3B. Braun Medical s.r.o., Prague, Czech Republic

**Introduction** Internal and external anti-infective coating of central venous catheters (CVCs) may reduce the rate of catheter colonization (CC) and bloodstream infection (BSI) [1]. Our objective was to evaluate the efficacy of a protective nonleaching polyhexanide coating on the rate of CC and BSI in ICU settings.

**Methods** A prospective, randomized, controlled, double-blind clinical trial was performed on multidisciplinary ICUs of two university hospitals in the Czech Republic between 2005 and 2010. A total of 680 patients were randomized to receive either coated CVC (Certofox® protect; B.
Braun Melsungen AG or standard CVC (Certofix®; B. Braun Melsungen AG). Primary objectives were the difference of the incidence of both CC and BSI between groups. Catheter colonization was defined as the growth of >1,000 colony-forming units using the sonication method. Results A total of 674 catheters were evaluated among which 58 catheters were excluded due to short indwelling time <3 days (an exclusion criterion). The two groups were similar with respect for the insertion site, place of insertion (ICU or surgical theatre), indwelling time, ICU stay and demographic indices. The coated CVC displayed similar incidence of CC as the standard CVC (17.36% vs. 18.67%, \( P = 0.747 \)) as well as incidence of catheter-related BSI (1.33% vs. 1.94%, \( P = 0.752 \)). The rate of BSI was significantly lower in protected CVCs (2.00% vs. 6.47%, \( P = 0.008 \)), and the incidence of BSI/1,000 catheter-days was lower in coated catheters (3.21 vs. 8.30, \( P = 0.036 \)) as well (Figure 1).

Conclusions Our results suggest that the use of external/internal polyhexamidine-coated CVCs is associated with significant reduction of BSI but not with the reduction of colonization rate.

Central line change in potential catheter-related bloodstream infection: target for intervention to reduce harm
R Davies, M Lowings, AT Jones, CJ Langrish
St Thomas’ Hospital, London, UK

Introduction Central venous catheterization is routine in critical care, but a potential source of harm. Forty-two per cent of bloodstream infections in England are central-line related [1], at a substantial cost to the health service. Early catheter removal is vital for source control where catheter-related bloodstream infection (CRBSI) is suspected. Furthermore, a model encompassing daily review and removal of unnecessary catheters has been shown to reduce the risk [2]. We studied the time from decision to removal of existing central venous catheters (CVCs), and evaluated potential reasons for delay.

Methods This is a retrospective review of practice at a 43-bed medical/surgical ICU at a London teaching hospital, using computerized patient records. All patients requiring a change of CVC over a 2-month period in 2010 were included. Change of CVC was defined as the time from decision to removal of the old CVC, incorporating new CVC insertion. Sepsis was defined as rising inflammatory markers, an impression of local/systemic infection, or emergency (unsterile) insertion. Routine change was defined as no signs of infection, usually at 5 to 7 days or if accidentally dislodged/blocked.

Results Seventy-eight CVC changes were performed, 45 (57.7%) for sepsis and 33 (42.3%) as routine. The median time to change a septic CVC was 742.5 minutes (106 to 2,038 minutes). The median time for a routine change was 611 minutes (130 to 1,759 minutes). On average, 70% of the time taken to change a CVC involved new catheter insertion. Where the tip position was confirmed with a chest X-ray scan, it took a median of 182 minutes longer (~97 to 946 minutes) to change the CVC. Check X-ray was documented in 28 (45.1%) of 62 internal jugular/subclavian CVCs and only five X-ray scans resulted in repositioning. Where inotropes/vasopressors were administered, it took a median of 209 minutes longer (106 to 599 minutes) for CVC change. Where coagulation products were administered, it took a median of 168.5 minutes longer (209 to 279 minutes) for CVC change. Conclusions Our data suggest that in our unit the duration of catheter change in the critically ill is a prolonged process, and took longer where potential harm is greatest. Check X-ray scans infrequently result in CVC repositioning, contribute to delays and could be performed after old-CVC removal. We plan to audit the changes we have made, and believe that the timely exchange of old CVCs should be incorporated into models aiming to reduce the impact of CRBSI.

P231
Clostridium difficile-associated diarrhoea in a tertiary referral neurocritical care centre
S Tripathy, C Katara, PV Nair
Walton Centre of Neurosciences, Liverpool, UK

Introduction Clostridium difficile-associated diarrhoea (CDAD) is associated with a mortality of up to 25% in susceptible patients. It occurs following long-term hospitalisation and prolonged antibiotic usage, particularly cephalosporins. Neurointensive care unit (NICU) patients on average have higher bed days, greater incidence of ventilator-associated pneumonia (VAP) and higher antibiotic use. We aimed to study the aetiology, acquisition rate and outcome of NICU-acquired CDAD.

Methods Intensive care admission and hospital infection control databases from April 2008 to August 2010 were studied and the case notes reviewed retrospectively. Patients who acquired CDAD within 48 hours of NICU admission were excluded. Diarrhoea was classified as mild, moderate or severe based on frequency and volume. Information on use of antibiotics, frequency, duration and type was gathered. Admission diagnosis, days of NICU stay and incidence of complications were noted.

Results Of the 2,212 patients with a total of 10,825 bed-days, nine patients developed CDAD. The median duration between ICU admission and development of CDAD was 11 (3 to 93) days (7 in other neurocritical care units). Median age of the patients was 55 (20 to 72) years. Patients had a mean 6.7 (±5.2) days of diarrhoea prior to a positive assay. At the time of diagnosis, four (44%) patients had moderate disease. Three patients had a perceived delay in discharge from the ICU (1 to 8 days) due to their infective status. Concurrent infections occurred in 77% of patients, 33% of which were VAP. Of the antibiotics used prior to CDAD diagnosis, 44% were cephalosporins. We found no additional risk factors for ICU-acquired CDAD. Identified risk factors for VCA-injured CDAD included age >65 (22%), antibiotics (67%), laxatives (100%), steroids (33%), proton pump inhibitors (88%) and medical device requirement (100%). All patients were emergency admissions, of which eight were neurosurgical. The one patient who had the most protracted disease was isolated with C. difficile ribotype 027.

Conclusions In spite of a patient population who is at high risk of CDAD, the rate of infection in our unit is 8.3 per 10,000 bed-days or 0.4% incidence, which is below the average incidence for general intensive care (10.6 per 10,000 bed-days) and neurocritical care units (0.6%) in the UK. This may be attributed to the presence of an efficient infection control team, isolation practices with patients immediately being isolated to barrier nursing and a protocol for CDAD detection as well as a high degree of awareness amongst the medical and nursing staff.

P232
A creep in the vancomycin minimum inhibitory concentration for Staphylococcus aureus in a tertiary care hospital in India
A Bhakta, M Bhattacharya, S Todi
AMRI Hospitals, Kolkata, India

Introduction Vancomycin minimum inhibitory concentration (MIC) creep has been observed in studies from western countries. Staphylococcus aureus strains with increased MIC to vancomycin are associated with worse outcomes compared with more susceptible strains. Recognition of this phenomenon – the development of reduced susceptibility to vancomycin, and the subsequent glycopeptide MIC creep – is important, since it may be a precursor to heterogeneous vancomycin intermediate S. aureus (hVISA) and VISA.

Methods In a study carried out in a tertiary care hospital in India, 176 clinically significant Gram-positive bacterial isolates were collected from January 2009 to October 2009. MICs were determined for vancomycin, teicoplanin, linezolid, daptomycin and cefoxitin (to screen for VISA and VRSA). In spite of a patient population who is at high risk of CRBSI, the data were analysed to determine if a creep occurred.

Results Of 176 isolates, 72 were MSSA, 16 MRSA, 68 Enterococcus spp. and 20 coagulase-negative staphylococci. No VISA or VRSA was isolated.
detected. Sixteen MRSA and 12 MSSA isolates have MIC 2. The MIC50 values of MRSA and MSSA were 1.5 and 1, respectively. The MIC90 values of MRSA and MSSA were 2 and 1.5, respectively. A total 80.5% of MSSA isolates have MIC of vancomycin ≥1. Enterococcus spp. had MIC50 of 1 and MIC90 of 3, whereas coagulase-negative staphylococci had MIC50 of 1 and MIC90 of 2. MIC90 of all the isolates for teicoplanin was between 2 to 3, for linezolid 1.5 to 3 and for daptomycin 0.50 to 0.75.

**Conclusions** A significant creep in the vancomycin MIC for *S. aureus* has occurred in an Indian hospital, which is of important concern as it may lead to treatment failure with vancomycin.

Prognostic impact of imported and newly-isolated methicillin-resistant *Staphylococcus aureus* in the ICU

S Ohshima, K Ota, T Tamura, Y Kidai, J Irai, K Suzuki, T Inagawa, Y Torikoshi, T Otani, T Sadamori, R Tsumura, V Iwasaki, N Hirohashi, K Tanigawa
Shiga University of Medical Science, Shiga, Japan

**Introduction** Methicillin-resistant *Staphylococcus aureus* (MRSA) is a leading pathogen of hospital-acquired pneumonia. The difference in outcome between patients with imported and newly-isolated MRSA in the ICU has not been well investigated. The aim of our study was to explore the incidence, risk factors and outcome in patients with imported and newly-isolated MRSA.

**Methods** Patients admitted to the ICU in our university between April 2009 and May 2010 were prospectively studied. Nasal swabs were collected from all patients on admission and subsequently collected weekly during the ICU stay. When patients were intubated, intratracheal aspirates were concurrently collected. The correlations of positive culture of MRSA with clinical variables were analyzed.

**Results** A total of 1,270 consecutive patients were enrolled. The median follow-up period was 404 days (range, 187 to 609). There were 803 males and 467 females. Median age was 63 (range, 1 to 97). Of these, imported MRSA was found in 124 (10%) patients, and newly-imported MRSA in 57 (4%) patients. The incidence of imported MRSA was associated with the co-morbidity of cardiovascular disease or malignancy and long hospital stay before admission to the ICU, whereas the incidence of newly-imported MRSA was associated with the positive culture in intratracheal aspirates or blood/intravenous catheter, the co-morbidity of shock, pneumonia, neurological diseases or trauma, increased number of isolated sites, higher APACHE II score, prolonged ICU stay and higher mortality during ICU stay. Although no statistical significance was found in total patients, the subset analysis of the male patients demonstrated that the outcome of newly-isolated patients was significantly poor compared with those of imported MRSA (P = 0.005). Multivariate analysis revealed that the new isolation of MRSA in the ICU (P = 0.03; hazard ratio (HR), 2.62), negative culture of MRSA in nasal swab (P = 0.02; HR, 4.18), ≥2 isolated sites (P = 0.01; HR, 4.59) and co-morbidity of ARDS (P = 0.002; HR, 4.63) were the independent poor prognostic factors.

**Conclusions** New isolation of MRSA during the ICU stay was associated with poor outcome particularly in male patients compared with imported MRSA. Clinicians should be aware of the high-risk group of MRSA infection. Strict hand hygiene plus a careful assessment of the patient, applying aggressive procedures such as patient isolation, staff cohorting, and active surveillance cultures should be indicated.

Increased mortality associated with methicillin-resistant *Staphylococcus aureus* infection in the ICU: results from the EPIC II study

H Hanberger, S Walther, for the EPIC II participants

Clinical and Experimental Medicine, Linköping, Sweden

**Introduction** Controversy continues regarding whether methicillin resistance increases mortality risk in *Staphylococcus aureus* infections. We assessed the role of methicillin resistance on survival of patients in the EPIC II study cohort with *S. aureus* infection.

**Methods** The EPIC II point-prevalence study of infection in critically ill patients was performed on 8 May, 2007. Demographic, physiological, bacteriological and therapeutic data were collected for all adult patients in 1,265 participating ICUs from 75 countries on the study day. ICU and hospital outcomes were recorded. We compared characteristics of patients with methicillin-sensitive (MSSA) and methicillin-resistant (MRSA) *S. aureus* infection. Co-morbidities, age, simplified acute physiology score II (SAPS II) score, site of infection, geographical region, and MSSA/MRSA were entered into a multivariable model and adjusted odds ratios (ORs) (95% CI) were calculated for ICU and hospital mortality rates.

**Results** On the study day, 7,087 of the 13,796 patients (51%) were classified as infected. There were 494 patients with MRSA and 505 patients with MSSA infections. There were no significant differences between the two groups in use of mechanical ventilation or hemofiltration/hemodialysis. Cancer and chronic renal failure were more prevalent in MRSA than in MSSA patients. ICU mortality rates were 29.1% and 20.5%, respectively (P <0.01) and corresponding hospital mortality rates were 36.4% and 27.0% (P <0.01). Multivariable analysis of hospital mortality for MRSA infection showed an adjusted OR of 1.48 (1.05 to 2.10), P = 0.03.

**Conclusion** In ICU patients, MRSA infection is more common in patients with co-morbid conditions, such as cancer and chronic renal failure, and is independently associated with an almost 50% higher odds of hospital death compared with MSSA infection.

Intrathecal (intraventricular) polymyxin B in the treatment of patients with meningoencephalitis caused by *Acinetobacter baumannii* and *Pseudomonas aeruginosa*

SK Macedo, IP Gonçalves, GVJD Bisp, LRd Almeida, LbDA Brito
São José do Açu Hospital, Itaperuna, Brazil

**Introduction** Intravenous therapy (IVT) with polymyxin B (PolyB), an antibiotic with similar pharmacological action to colistin (PolyE), by external ventricular derivation (EVD) has the main goal of offering major bioavailability of the drug, since its use by intravenous and direct action are restricted by the blood–brain barrier, with penetration of only 25%. *Pseudomonas aeruginosa* is a Gram-negative bacterium, multidrug resistant, which has a characteristic of secreting exotoxin A. Along with *Acinetobacter baumannii*, it has expressed a great risk to the patients with meningoencephalitis. The patient of the present report had arterial venous malformations followed by hemorrhagic stroke, which caused elevated intracranial pressure. The objective is to show an example of the effect of IVT PolyB in a patient with meningoencephalitis infection by multidrug-resistant Gram-negative bacteria (*A. baumannii* and *P. aeruginosa*), common in the ICU.

**Methods** A literature review was made on the subject of therapy with PolyB about the pharmacological characteristics, nephrotoxicity and neurotoxicity. A comparative table of the profile of resistance of the strain treated in this study was created, with the intrinsic resistance of the species. Also, the development of liquor evolution (culture and routine) of the patient before the treatment was monitored, until negative liquor. We analyzed the life and effectiveness of EVD, the colonizer germ and monitoring of the serial aspect of the liquor.

**Results** The patient was treated with intravenous and intrathecal administration of PolyB (IVT) between 14 November and 28 November 2008. On 14 November 2008, therapy was started with PolyB intravenous administration of 1,500,000 UI (20,000 UI/kg/day) once a day, on every day of treatment, and IVT by EVD: 50,000 UI in solution once a day during the first 3 days, and on alternate days for all of the treatment. As a result of the use of intrathecal PolyB intravenously, effectiveness was proven in the routines of liquor negative for such germs, showing no reports of neurotoxicity and nephrotoxicity.

**Conclusions** IVT PolyB proved to be very efficient, treating this meningoencephalitis quickly. No toxic effect was associated with the drug.
Tigecycline counteracted emerging circulatory deterioration without

**Conclusions**

$P < 0.05$), but not the doxycycline group.

During the experiment in the placebo group compared with the tigecycline and placebo groups during the experiment 0 to 6 hours.

We measured inflammatory, hemodynamic and respiratory variables.

Methods

Eighteen piglets weighting 25.0 ± 2.2 (mean ± SD) were randomized to receive tigecycline 100 mg, doxycycline 200 mg or placebo and subjected to 6 hours of endotoxin infusion of 2 μg/kg/hour.

Results

TNFα was lower in the doxycycline group compared with the tigecycline and placebo groups during the experiment 0 to 6 hours ($P < 0.05$). The mean arterial pressure decline from baseline was greater during the experiment in the placebo group compared with the tigecycline group 0 to 6 hours ($P < 0.05$), but not the doxycycline group.

Conclusions

Doxycycline demonstrated anti-inflammatory properties. Tigecycline counteracted emerging circulatory deterioration without affecting the proinflammatory cytokine response in this model.

Blood transfusions: an independent risk factor for the development of Candida infections in critically ill surgical patients

G Burghi, G Ortiz, H Bagnulo

Hospital Maciel, Montevideo, Uruguay

Introduction

Blood transfusions are associated with infectious complications. Despite this, only a few studies link the use of blood transfusions with the development of fungal infections. This study was performed to assess risk factors associated with Candida colonization and infection.

Methods

A retrospective study including all patients admitted to the ICU due to severe abdominal sepsis or severe pancreatitis between July 2005 and July 2010. Factors analyzed were: shock, insulin use, number of surgeries, mechanical ventilation, days of central catheters, treatment with corticosteroids, parenteral nutrition, red blood cell transfusions, and use of antibiotics. Risk factors for Candida colonization and infection were identified by multivariate logistic regression.

Results

We analyzed 86 patients with severe abdominal sepsis and severe pancreatitis. Mean age 62 ± 16, SAPS II 47 ± 25, 70% required invasive ventilation, and 61% presented shock. Twenty patients (23%) were colonized by Candida. Independent risk factors for Candida colonization were the use of parenteral nutrition (OR, 3.6; 95% CI, 1.0 to 12.6; $P = 0.03$) and transfusion of at least 4 volumes of red blood cells (OR, 12.8; 95% CI, 2.0 to 79; $P = 0.006$). Seven patients (8%) had invasive candidiasis. Independent risk factors associated with this infection were: prior colonization by at least two sites (OR, 10.6; 95% CI, 1.8 to 61; $P = 0.008$), and transfusion of at least 4 volumes of red blood cells (OR, 9.7; 95% CI, 1.6 to 59; $P = 0.01$). Mortality in the Candida infection group was 71% versus 53% in non-infected nor colonized patients ($P = 0.3$).

Conclusions

Candida infection is always preceded by colonization. The need for antifungal treatment should be based on the degree of colonization. Restrictive transfusional strategies should be established in these patients to reduce invasive Candida infections.

Chinese survey of candidasis in ICUs: China-SCAN study

HB Qiu, for China-Scan Study Group

Zhongda Hospital of Southeast University, Nanjing, China

Introduction

This is the first national multicenter epidemiology study of invasive candida infections (ICIs) within ICUs in China. The objectives included describing the epidemiology, patient characteristics and management of these ICIs.

Methods

The study used a prospective observational design. A total of 68 ICUs in China participated. The study was initiated on 1 November 2009 and will close on 30 April 2011. During the study period all consecutive patients above 18 years diagnosed as proven ICU after being admitted into the ICUs were eligible for enrollment. For each episode of ICU, demographic data, underlying diseases, severity of illness, risk factors, diagnosis, reported pathogen of fungal infection, process of treatment and survival at discharge were recorded. A total of 203 ICU cases were identified by the end of October 2010; since CRF collection and data management for part of the cases are ongoing, here we report the interim analysis results of 145 proven ICIs.

Results

Among 145 eligible ICU patients, 134 (92.4%) had isolated candidemia, two (1.4%) had invasive candidiasis with candidemia, and 8 (5.5%) had mixed infections.
nine (6.2%) had invasive candidiasis without documented candidemia. The median time ICU occurred was 9 days after ICU admission. The mean APACHE II was 26.6 at ICU admission (SD 7.2). The frequency of risk factors within 2 weeks before ICU were 107 patients (73.8%) with central venous catheterization, 117 (80.7%) with antibiotic therapy ≥ 5 days, 112 (77.2%) with invasive mechanical ventilation and 62 (42.8%) with total parenteral nutrition. The case fatality ratio of ICU in the ICU was 34.5% (50/145). A total of 156 isolates were collected, C. albicans accounted for 48.1% (75/156) of the isolates, followed by C. parapsilosis (14.1%), C. tropicalis (14.1%) and C. glabrata (9.6%). Seventy-five patients were reported with C. albicans infection (51.7%), among them five patients were reported as co-infected with other candida. Forty-three patients were reported with C. albicans (9.6%), Seventy-five patients were C. glabrata (14.1%), and C. parapsilosis (14.4%) and 3/201 (1.5%) of patients, respectively. The most common treatment-related AE was erythema in four patients (2.0%). Other treatment-related AEs occurred in ≤ 1.5% of non-neutropenic patients.

Conclusions ANI was effective and safe for the treatment of C/IC in selected populations of non-neutropenic ICU patients.

Critical Care 2011, Volume 15 Suppl 1

Introduction A recent study found anidulafungin (ANI) safe and effective for candidemia/invasive candidiasis (C/IC) in selected populations of ICU patients [1]. A post hoc analysis of this study was performed to evaluate the efficacy of ANI in the same populations, but in non-neutropenic C/IC patients only.

Methods A prospective, open label, multinational, phase 3b study in adult ICU patients (APACHE II score < 25) with ≥ 1 of the following: post-abdominal surgery; age ≥ 65 years; renal/hepatic insufficiency; solid organ transplant; neutropenia; and/or solid tumor. C/IC was confirmed from 96 hours before to 48 hours after the start of study treatment. Patients received i.v. ANI (200 mg on day 1, 100 mg/day thereafter) for ≥ 10 days, with optional oral azole step-down therapy, for a total treatment duration of 14 to 56 days. Primary efficacy endpoint was global response at end of all therapy (EOT) in the evaluable modified intent-to-treat (eMITT) population; that is, excluding patients with missing/unknown responses. For the present analysis, all patients with neutropenia were excluded.

Results The total MITT population (that is, confirmed C/IC and ≥ 1 dose of ANI) included 170 patients, 157 (92.4%) of whom were non-neutropenic. In these patients at baseline, 69.4% had candidemia, mean APACHE II score was 16.3 (range 4 to 26) and mean SOFA score 7.4 (range 0 to 20). In non-neutropenic eMITT patients, global response at EOT was 71.1% (95% CI = 62.9, 78.4). At the end of i.v. therapy, 2 weeks post-EOT and 6 weeks post-EOT the global response was 72.4%, 61.2% and 52.0%, respectively. When missing/unknown responses were included and classed as failures, global success was 64.3% at EOT. The 90-day Kaplan–Meier survival estimate was 55.0% (95% CI = 47.2, 62.9).

Among all non-neutropenic patients with ≥ 1 dose of ANI, treatment-related (due to ANI and/or azole) AEs and serious AEs occurred in 29/201 (14.4%) and 3/201 (1.5%) of patients, respectively. The most common treatment-related AE was erythema in four patients (2.0%). Other treatment-related AEs occurred in ≤ 1.5% of non-neutropenic patients.

Conclusions ANI was effective and safe for the treatment of C/IC in selected populations of non-neutropenic ICU patients.

Pharmacokinetics of micafungin in patients with severe burn injuries
J Sasaki1, S Kishino1, S Horii1, N Akawa1
1 Keio University School of Medicine, Tokyo, Japan; 2 Meiji Pharmaceutical University, Tokyo, Japan

Critical Care 2011, Volume 15 Suppl 1

Introduction Micafungin (MCFG), an echinocandin antifungal agent, exhibits more potent antifungal activity against a broad spectrum of clinically important Candida and Aspergillus species [1]. However, there are few pharmacokinetic data of antifungal agents for burned patients, and determination of the dosage for these populations requiring initially a large quantity of fluid therapy can trouble burn surgeons and intensivists. The purpose of this study is to obtain the pharmacokinetic data for MCFG in severe burned patients.

Methods In six patients with severe burn injuries within 14 days after injuries (19 to 82 years old, 36 to 85% TBSA), we measured the plasma concentration of MCFG by high-performance liquid chromatography [2] after drip infusion of MCFG, at 200 to 300 mg/day over a 1-hour period. Blood samples were collected at the end of the first administration of MCFG (peak value after initial administration; A point), immediately before the second dosing (trough value after initial administration; B), at the end of the fourth dosing (steady-state peak value; C), and immediately before the fifth dosing (steady-state trough value; D). The control value of plasma concentration of MCFG assumed the pharmacokinetics value obtained from healthy volunteers.

Results The plasma concentration of MCFG at the A point were 10.1 to 24.2 μg/ml, 1.8 to 6.1 μg/ml at B, 11.3 to 27.9 μg/ml at C, and 2.3 to 7.9 μg/ml at D. In both peak and trough values there was a good correlation between the plasma concentration of MCFG and the dose of MCFG per kilogram body weight the same as cases of healthy volunteers (Figure 1).

Conclusions These results suggest that MCFG can be administered safely to burned patients without adjusting the dose.

Invasive aspergillosis in critically ill hematology patients: outcomes and prognostic factors associated with mortality
G Burghi1, V Lemiale, E Azoulay
Hospital Saint-Louis, Université Paris VII, Paris, France

Introduction Invasive aspergillosis (IA) is documented in up to 15% of critically ill hematology patients admitted for acute respiratory failure. The disease is believed to be mostly deadly. Because diagnostic, preventive and therapeutic strategies for IA have changed over the past decade, we sought to appraise outcomes in hematology patients receiving mechanical ventilation for IA.

Methods Determinants of hospital mortality were identified in hematology patients admitted to the ICU for acute respiratory failure from proven or probable IA.

Results Fifty-nine patients received mechanical ventilation for IA over the 10-year study period. Thirty-six (62%) were neutropenic, 19 (32%) were receiving long-term steroids, and 13 (22%) were recipients of allogeneic BMT. Diagnosis was based on clinical and radiographic features, associated with either Aspergillus isolation (48 patients, including 25 bronchial aspiration, 17 BAL, six BAL + bronchial aspiration) or circulating galactomannan alone (11 patients). In 33 patients positive galactomannan was associated with Aspergillus isolation. Five cases were proven on autopsy. Associated bacterial infection was documented in 21 (35.6%) patients. Antifungal therapy included conventional amphotericin (50%), voriconazole (49%), liposomal amphotericin (32%), or caspofungin (19%). Seventeen (28.8%) patients had two lines of therapy and nine patients received a combination of voriconazole (32%), or caspofungin (19%). Seventeen (28.8%) patients had two lines of therapy and nine patients received a combination of voriconazole (32%), or caspofungin (19%).

Conclusions The use of mechanical ventilation in patients with IA complicating HM is associated with a high, yet not constant, mortality (OR = 0.12 (0.03 to 0.59)) were associated with lower mortality. The use of voriconazole (OR = 0.19 (0.04 to 0.91)) and localized disease (OR = 5.91 (1.04 to 33.5)) was associated with increased mortality, whereas associated bacterial infection, and 44% in patients treated with voriconazole. Associated bacterial infection was independently associated with increased mortality (OR = 5.91 (1.04 to 33.5)), whereas the use of voriconazole (OR = 0.19 (0.04 to 0.91)) and localized disease (OR = 0.12 (0.03 to 0.59)) were associated with lower mortality.

Effects of endotoxin on pacemaker funny current in HEK 293 cells
VP Papaioannou1, A Van Ginneken1, AV Verkerk2, JB De Bakker2
1Alexandroupolis University Hospital, Alexandroupolis, Greece; 2Academic Medical Center, Amsterdam, the Netherlands

Introduction Different animal in vitro studies have concluded that lipopolysaccharide (LPS) can alter electrophysiological properties of ionic currents in cardiac myocytes. There is only one study in the literature that found reduced activation of the pacemaker funny current (IF), encoded by the hyperpolarization-activated cyclic nucleotide modulated-4 (HCN4) gene family, in human atrial cells after administration of LPS.

Methods Twenty human embryonic kidney (HEK) 293 cells were transfected with Toll-like receptors-4 (TLR4), CD14 and HCN4 cDNAs and after 24 hours were incubated with 1 μg/ml (10 cells) or 10 μg/ml (10 cells) of LPS (from Escherichia Coli, Sigma, St Louis, USA). In addition, 50 μM soluble MD-2 protein was added to the culture medium for enhancing the responsiveness of TLR4 to LPS. Twenty-four hours after LPS addition, electrophysiological recordings were performed at 36°C with the whole-cell patch clamp technique, using an Axopatch 200B amplifier (Molecular Devices, Sunnyvale, CA, USA). IF current properties were measured during 6-second hyperpolarizing steps (range –30 to –120 mV), from a holding potential of –30 mV. Voltage control, data acquisition and analysis were accomplished using custom software.

Results Incubation of cells with both 1 and 10 μg/ml LPS was found to significantly impair IF related to controls, by suppressing the current at membrane potentials between –60 and –90 mV and slowing down current activation. Funny current in LPS-treated cells showed more negative half-maximum activation voltage ($V_{1/2}$) values and slope factors (k), derived from voltage-dependent activation curves after Boltzmann fitting to experimental data (1 μg/ml: $V_{1/2}$ = –80 ± 3.7 mV and k = –14.9 ± 3.4 mV, 10 μg/ml: –96 ± 4.5 and –31.2 ± 6.7, respectively), than the control cells ($V_{1/2}$ = –75 ± 2.8, k = –9.7 ± 2.3, P < 0.001 for all comparisons).

Conclusions IF currents densities between –60 and –90 mV were significantly higher in untreated cells (0.67 ± 0.5 pA/pF) than in 1 and 10 μg/ml incubated LPS cells (0.43 ± 0.3 and 0.09 ± 0.05, respectively, P < 0.001 for all comparisons).

Influence of an immunoglobulin-enriched (IgG, IgA, IgM) solution on activation and immunomodulatory functions of peripheral blood mononuclear cells in a LPS second-hit model
C Duerr, A De Martin, M Sachet, T Konrad, S Baumann, A Spitterl
Medical University of Vienna, Austria

Introduction Immunoglobulin molecules have opposing functions by inducing proinflammatory and anti-inflammatory responses in innate immune effector cells. In the setting of acute inflammation, Toll-like receptors sense the presence of microbial components within minutes. TLR signalling in monocytes and macrophages leads to the production of numerous proinflammatory cytokines which accumulate in the activation of both the innate and adaptive immune system. It is well established that repeated endotoxin stimulation triggers immunological hyporesponsiveness of the monocyctic lineage, which is demonstrated by a reduced capacity to produce TNFα upon LPS stimulation. In an in vitro model we investigated the impact of immunoglobulins on activation of mononuclear cells obtained from healthy probands and from patients suffering Gram-negative sepsis.

Methods Whole blood (n = 5) and PBMCs (n = 5) from healthy volunteers as well as whole blood from patients in the early (n = 8) and in the late (n = 8) phase of sepsis were treated with an immunoglobulin-enriched solution containing IgG, IgA, and IgM (IgGAM). Cells were challenged with various concentrations of LPS in a second-hit model and TNFα secretion was measured by ELISA. In addition, monocyte HLA-DR, CD64 and CD11b expression as well as phagocytosis and oxidative burst were analysed by flow cytometry. Proliferation and cytokine release of ConA and/or IL-2 stimulated lymphocytes were undertaken.

Results In healthy donors upon two-time LPS stimulation IgGAM incubation resulted in a significant decrease of TNFα secretion administration in a time-dependent and dose-dependent manner. Similar effects were observed in whole blood from patients in the early phase of sepsis. HLA-DR, CD11b and CD64 expression from monocytes of healthy probands declined significantly after LPS expression, which was not observed in septic patients. Interestingly in both groups the administration of IgGAM had no effects on phagocytosis and oxidative burst. Lymphocyte proliferation and cytokine release were significantly impaired in both groups.

Conclusions The immunoglobulin-enriched solution possesses a distinct immune modulatory effect in vitro on monocytes/monocyte-derived macrophages and lymphocytes from both septic patients and healthy volunteers, especially upon short-term LPS exposure and in the early phase of sepsis.

Lipopolysaccharide induces mitochondrial dysfunction in rat cardiac microvascular endothelial cells
M Vuda, M Chiusa, SM Jakob, J Takala, C Zuppinger, S Djafarzadeh
Bern University Hospital and University of Bern, Switzerland

Introduction Endothelial injury and dysfunction are key pathophysiological processes in sepsis. The aim of the study was to evaluate...
the effects of bacterial lipopolysaccharide (LPS) on cellular respiration of rat primary cardiac microvascular endothelial cells (CMEC).

Methods CMEC were isolated from adult (250 to 300 g) male Wistar rats and cultured. Cells were exposed to LPS (1 μg/ml) for 4, 8, 16 hours and cellular respiration was measured by high-resolution respirometry (Oxygraph-2k; Oroboros Instruments, Innsbruck, Austria). Activation of caspase-3 protein as an early apoptotic event was examined by western blot analysis. Electron microscopy was performed to reveal any alterations in mitochondrial morphology.

Results After 4 and 8 hours of LPS incubation (1 μg/ml) no significant changes in CMEC mitochondrial respiration were observed. However, cells treated with LPS for 16 hours exhibited a significant reduction in the maximal complex I-dependent (control: 146 ± 45 pmol/(second*million cells)) and IV-dependent (control: 148 ± 89 pmol/(second*million cells)) mitochondrial respiration (n = 16) (Figure 1). Relatively little, if any, processing of procaspase-3 to active caspase-3 was detected in untreated cells or in cells treated with LPS (1 μg/ml, 16 hours of incubation) (data not shown), and electron microscopy examination revealed no major alterations in cellular and mitochondrial ultrastructure under LPS treatment (Figure 2). Statistical analysis for cellular respiration was performed using a paired t test.

Conclusions The data suggest that prolonged exposure to LPS impairs CMEC complex I-dependent and IV-dependent respiration slightly but significantly, without apparent signs of apoptosis or mitochondrial ultrastructural damage.

P247 Influence of body mass index on the innate immune response during human endotoxemia
R Van der Pluijm
UMC St Radboud, Nijmegen, the Netherlands

Introduction Accumulating data suggest a protective effect of obesity in the case of severe infections. Higher baseline levels of the proinflammatory cytokine TNFα as well as more pronounced TNFα release following whole blood stimulation with endotoxin are reported in patients with a higher body mass index (BMI). This more pronounced proinflammatory response in obese patients may enable a rapid and more effective clearance of microbial pathogens. The effect of the body mass index on the innate immune response in vivo has not been assessed.
Methods The immune response and BMI of 69 healthy subjects that were included in several experimental endotoxemia studies were analyzed. Endotoxemia was induced by the administration of 2 ng/kg *Escherichia coli* lipopolysaccharide. Concentrations of TNFα and IL-10 were serially determined (Luminex assay). Areas under the curve of cytokine levels were calculated and analyzed with unpaired t tests. All data are expressed as mean ± SEM of n subjects.

Results All subjects showed increased production of both proinflammatory cytokine TNFα and anti-inflammatory cytokine IL-10 (Figure 1). The area under the curve of TNFα levels was related to the BMI (Figure 2) as subjects with BMI >24 kg/m² released more TNFα than those with BMI <21 kg/m² (P = 0.04). An opposite trend of IL-10 levels was observed in association with higher BMI (P = 0.12). The quotient of TNFα/IL-10 AUC levels, serving as a readout of the pro/anti-inflammatory balance of a subject, showed a more proinflammatory response in subjects with a higher BMI compared with those with a lower BMI (P = 0.03) (Figure 2).

Conclusions This study is the first to demonstrate that a higher BMI is associated with a shift in the pro/anti-inflammatory balance towards a more pronounced proinflammatory immune response in humans in vivo.

![Figure 1 (abstract P247). Effects of 2 ng/kg *Escherichia coli* endotoxin (LPS) (administered at 0 hours) in subjects with BMI <21 and BMI >24 kg/m² on the production of TNFα and IL-10. Data expressed as mean ± SEM.](image1)

![Figure 2 (abstract P247). AUC of TNFα and IL-10 and the TNFα/IL-10 ratio in subjects with BMI <21, BMI 21 to 24 and BMI >24 kg/m². Data expressed as mean ± SEM.](image2)

Effect of bacterial load versus duration of exposure to bacteria on plasma TNFα concentrations in porcine fecal peritonitis

T Correa, L Brander, S Djafarzadeh, R Schröder, J Takala, A Reintam Blaser, M Vuda, S Mathias Jakob

University Hospital Bern – Inselspital and University of Bern, Switzerland

Introduction The clinical relevance of preclinical sepsis research has been questioned [1]. This may in part be the result of varying degrees of experimental inflammatory insults. The objective of this study was to quantify inflammation based on plasma TNFα levels after exposure to two different bacterial loads, and after different lengths of bacterial incubation in the peritoneal cavity.

Methods We retrospectively evaluated plasma TNFα concentrations measured before and 24 hours after fecal peritonitis induced by 1 g/kg autologous feces (16 anesthetized pigs, median weight: 40.0 kg) and after 6, 12 and 24 hours of fecal peritonitis induced with 2 g/kg autologous feces (24 anesthetized pigs (n = 8/group); median weight: 41.0 kg). All animals were resuscitated with fluids, norepinephrine and antibiotics, and were mechanically ventilated according to standardized protocols. Differences along time after fecal peritonitis induced with 2 g/kg feces were assessed by ANOVA for repeated measures. Comparison between the two models (1 g/kg vs. 2 g/kg) after 24 hours of peritonitis was performed with an independent t test.

Results TNFα increased from baseline to 6, 12 and 24 hours of peritonitis induced with 2 g/kg feces (P <0.001 for time–group interaction) (Figure 1). The mean (± SD) plasma TNFα levels measured 24 hours after fecal peritonitis induced with 1 and 2 g/kg were 255 ± 178 pg/ml and 233 ± 124, respectively (P = 0.75; 95% CI for the difference: –124 to 169 pg/ml).
P249
Does leukocyte apoptosis play any role in the pathogenesis of experimental pancreatitis?

D Zotos1, T Adamis1, A Pistiki1, K Louis1, E Giamarellos-Bourboulis2

1University of Athens, Medical School, Athens, Greece; 2Attikon University Hospital, Athens, Greece

Introduction The role of apoptosis of leukocytes for the final outcome of necrotizing pancreatitis remains to be elucidated.

Methods Experimental pancreatitis was induced in rabbits after ligation of the common pancreatic duct. Animals were assigned into sham-operated (group A, n = 8) infused 0.3 ml of ethanol 99% above the ligation; into nine infused 0.3 ml of one 20% solution of taurocholic acid above the ligation (group B, n = 9); and into 10 infused 0.3 ml of one 20% solution of taurocholic acid above the ligation (group C, n = 10). Blood was sampled at serial time intervals; apoptosis of lymphocytes, monocytes and neutrophils was assessed by flow cytometry; malondialdehyde (MDA) was estimated by the thiobarbiturate assay and passage through an HPLC system. After death, quantitative tissue cultures were done.

Results Median survival of group A was 28 days; of group B was 5 days (log-rank: 4.858, P = 0.028). Mean log$_{10}$ of bacteria in blood for groups A and B at 2 hours was 1.59 and 1.21 (P = NS); at 4 hours 1.61 and 1.97 (P = NS); at 24 hours 1.28 and 1.02; and at 48 hours 1.29 and 1.00 (P = NS). Respective rates of apoptosis of lymphocytes at 2 hours were 17.1 and 22.2% (P = NS); at 4 hours 17.9 and 24.0% (P = NS); at 24 hours 18.3 and 21.9% (P = NS); and at 48 hours 20.5 and 22.8% (P = NS). Respective rates of apoptosis of monocytes at 2 hours were 32.8 and 36.0% (P = NS); at 4 hours 42.8 and 39.3% (P = NS); at 24 hours 54.5 and 62.1% (P = NS); and at 48 hours 52.5 and 64.3% (P = 0.042). Respective median serum MDA of groups A and B were 1.05 and 2.06 μmol/ml at baseline (P = NS); 0.93 and 2.54 μmol/ml at 2 hours (p: 0.028); 2.30 and 1.02 μmol/ml at 4 hours (P = NS); 1.47 and 2.05 μmol/ml at 24 hours (P = NS); and 1.71 and 1.85 μmol/ml at 48 hours (P = NS). Mean log$_{10}$ of bacterial growth in the liver of group A and of group B on sacrifice was 3.47 and 1.32, respectively (P = 0.043); and in the right kidney was 5.78 and 1.94, respectively (P = 0.004).

Conclusions IFNγ prolongs survival when administered after induction of experimental pancreatitis by E. coli. Its effect is mediated through: enhanced phagocytosis as evidenced by increase of oxidant stress and decrease of tissue bacterial load; and modulation of inflammation as evidenced by increase of apoptosis of monocytes.

P250
IFNγ prolongs survival in experimental Escherichia coli pyelonephritis: implications for favorable phagocytosis

M Katsaris1, T Adams1, A Pistiki1, M Georgitsi1, A Pistiki1, M Christos1, E Giamarellos-Bourboulis1

1University of Athens, Medical School, Athens, Greece; 2Attikon University Hospital, Athens, Greece

Introduction IFNγ is a promising immunomodulator in sepsis because it is thought it may reverse immunoparalysis and improve phagocytosis. Its effect was investigated in experimental pyelonephritis and sepsis.

Methods Experimental pyelonephritis by Escherichia coli was induced in 18 rabbits after ligation of the right pelvo-ureteral junction and infusion of one 1 x 10$^7$ log-phase cfu/ml inoculum above the ligation. Animals were assigned into 10 controls (group A) and into eight administered intravenously 0.1 μg/kg IFNγ 30 minutes after bacterial challenge (group B). Blood was sampled at serial time intervals; quantitative cultures were done; apoptosis of lymphocytes and of monocytes was assessed by flow cytometry; malondialdehyde (MDA) was estimated by the thiobarbiturate assay and passage through an HPLC system. After death, quantitative tissue cultures were done.

Results Median survival of group A was 3 days and of group B was 18 days (log-rank: 4.858, P = 0.028). Mean log$_{10}$ of bacteria in blood for groups A and B at 2 hours was 1.59 and 1.21 (P = NS); at 4 hours 1.61 and 1.97 (P = NS); at 24 hours 1.28 and 1.02; and at 48 hours 1.29 and 1.00 (P = NS). Respective rates of apoptosis of lymphocytes at 2 hours were 17.1 and 22.2% (P = NS); at 4 hours 17.9 and 24.0% (P = NS); at 24 hours 18.3 and 21.9% (P = NS); and at 48 hours 20.5 and 22.8% (P = NS). Respective rates of apoptosis of monocytes at 2 hours were 32.8 and 36.0% (P = NS); at 4 hours 42.8 and 39.3% (P = NS); at 24 hours 54.5 and 62.1% (P = NS); and at 48 hours 52.5 and 64.3% (P = 0.042). Respective median serum MDA of groups A and B were 1.05 and 2.06 μmol/ml at baseline (P = NS); 0.93 and 2.54 μmol/ml at 2 hours (p: 0.028); 2.30 and 1.02 μmol/ml at 4 hours (P = NS); 1.47 and 2.05 μmol/ml at 24 hours (P = NS); and 1.71 and 1.85 μmol/ml at 48 hours (P = NS). Mean log$_{10}$ of bacterial growth in the liver of group A and of group B on sacrifice was 3.47 and 1.32, respectively (P = 0.043); and in the right kidney was 5.78 and 1.94, respectively (P = 0.004).

Conclusions IFNγ prolongs survival when administered after induction of experimental pyelonephritis by E. coli. Its effect is mediated through: enhanced phagocytosis as evidenced by increase of oxidant stress and decrease of tissue bacterial load; and modulation of inflammation as evidenced by increase of apoptosis of monocytes.

P251
Regulation of endothelial function by coagulation proteases in sepsis

JN McLaughlin1, R Ramachandran2, AM Kaynar1, SD Shapiro1, DC Angus1, AB Malik2

1University of Pittsburgh School of Medicine, Pittsburgh, PA, USA; 2University of Illinois at Chicago, IL, USA

Introduction Thrombin and activated protein C (aPC) are two pleiotropic proteases whose opposing functions in hemostasis and endothelial function are dysregulated during sepsis. Exogenous supplementation of aPC, the ligand for endothelial protein C receptor (EPCR), is the only known therapeutic shown to reduce mortality in severe septic patients. Paradoxically, both thrombin and aPC signal the endothelium via the same receptor, protease-activated receptor-1 (PAR-1), by cleaving its N-terminus to produce an identical tethered ligand, yet result in opposing signaling networks. Once activated, PAR-1 triggers at least three separate signaling pathways (Gi, Gq, G13) and for propidium iodine and flow cytometric analysis. On death or for propidium iodine and flow cytometric analysis. On death or sacrifice the pancreas was removed. Fat necrosis was assessed by histology; quantitative tissue cultures were done.

Results Median survival of group A was 28 days; of group B was 5 days (log-rank vs. group A: 4.155, P = 0.042); and of group C was 1.5 days (log-rank vs. group A: 10.356, P = 0.001). Mean percentage pancreatic necrosis of groups A, B and C was 2.5, 45.0 and 42.0%, respectively. Respective mean log$_{10}$ of bacteria in the liver was 1.00, 3.13 and 2.48 cfu/g; in the lung 1.26, 2.90 and 2.56 cfu/g; in the spleen 1.00, 3.72 and 2.37 cfu/g; and in the right kidney 1.00, 2.88 and 2.85 cfu/g. Respective median apoptosis of lymphocytes within the first 24 hours from induction of pancreatitis was 22.58, 23.45 and 24.19% (P = NS) whereas respective median apoptosis of monocytes was 41.02, 43.66 and 47.92% (P = NS) and of neutrophils was 76.84, 79.49 and 83.94% (P = 0.034).

Conclusions Survival in experimental necrotizing pancreatitis depends on the density of taurocholate. In spite of the existence of marginal differences in apoptosis of neutrophils occurring early during the course of the disease, it seems that apoptosis is not a major driver to death; instead, bacterial translocation seems to be the main route to death.
Methods We used bioluminescent resonance energy transfer to dynamically monitor the interaction of recombiant PAR-1 and EPCR in HEK cells. The effect of EPCR on PAR-1-G protein selectivity was determined by EPCR-sRNA knock down in cultured endothelial cells. Relative activation of Gq was determined by assaying agonist-induced intracellular calcium mobilization. G13 activation was determined by monitoring agonist-induced changes transendothelial electrical resistance across monolayers.

Results We found that in the absence of protease ligands, unactivated PAR-1 dimmers interact with EPCR. However, proteolytically activated PAR-1/EPCR interaction was maintained with aPC but not thrombin. Both aPC and thrombin induced G13 signaling; however, aPC failed to activate Gq compared with thrombin. aPC-induced PAR-1/Gq signaling appears to be impaired by aPC-bound EPCR and is relieved when EPCR is depleted using siRNA.

Conclusions aPC-bound EPCR neutralizes the proinflammatory function of PAR-1 signaling by maintaining interaction with activated PAR-1, thereby abrogating Gq signaling. Thus it is not the difference in protease activation between thrombin and aPC, but rather the ability of aPC to direct PAR-1/EPCR dimerization that controls PAR-1 signaling, and thereby provides the therapeutic barrier protective/anti-inflammatory effects associated with aPC treatment.

Effect of HO-3089 PARP inhibitor on inflammatory response
M Nemeth1, T Leiner1, K Tanczos2, A Mikor3, Z Molnar2, K Kovacs2
1University of Pecs, Hungary; 2University of Szeged, Hungary

Introduction The activation of poly-ADP-ribose-polymerase enzyme (PARP) plays an important role in the pathophysiology of sepsis [1]. In previous animal models, lipopolysaccharide-induced systemic inflammatory response was significantly reduced by the inhibition of PARP [2]. The aim of our study was to investigate the effect of PARP inhibition on systemic inflammation in a septic animal model.

Methods In a prospective, randomized study, anaesthetized CFY rats were divided into four groups (five/group): cecal ligation group (CL), cecal ligation and puncture group (CLP), CLP with PARP inhibition (CLP+Pi) group and sham group. PARP inhibition was performed by HO-3089 (a novel PARP inhibitor) given intraperitoneally (10 mg/kg). Heart rate, invasive blood pressure and the rectal temperature were monitored. Data were recorded every 15 minutes. To identify the inflammatory response, IL-6 and TNFα were measured by quantitative sandwich enzyme immunoassay technique. Blood samples were taken before the CLP (t0), 2 hours (t1) and 6 hours (t2) after the CLP.

Results IL-6 and TNFα were significantly higher in the CLP and CLP+Pi groups at t2 as compared with t1 (CLP: P<0.001, P<0.001; CLP+Pi: P<0.002, P<0.001), and also as compared with the CL and sham groups at t1 (CL vs. CLP: P<0.001, P<0.001; CL vs. CLP+Pi: P<0.001; P<0.001). Additionally, in the CLP+Pi group the IL-6 level was lower than in the CL group at t1, but the difference was not significant (P=0.074). There was no significant difference in TNFα between the CLP and CLP+Pi groups either.

Conclusions The initial results of this study could not show a significant effect of the HO-3089 PARP inhibitor in CLP caused systemic inflammatory response. However, the tendency of lower IL-6 in the treated group warrants the completion of the experiment.

Inflammatory mediator modulation with specific or selective adsorbents
A Schildberger, T Buchacher, V Weber, D Falkenhagen
Danube University Krems, Austria

Introduction Modulation of inflammatory mediators with specific or selective adsorbents may represent a promising supportive therapy for septic patients. The aims of this study were to compare the influence of specific or selective polymeric adsorbents on endothelial cell activation and to test various adsorbents for binding of high mobility group box 1 (HMGB1), a late mediator in sepsis.

Methods Human umbilical vein endothelial cells (HUVEC) were activated with a conditioned medium that was obtained by stimulation of mononcytic THP-1 cells with 10 ng/ml lipopolysaccharide from 
Pseudomonas aeruginosa [1]. Mediator modulation was performed with either a specific adsorbent for TNFα, which is based on sepharose particles functionalized with anti-TNFα antibodies, or a selective albumin-coated polystyrene divinylbenzene copolymer (PS-DVB).

Endothelial cell activation was monitored for up to 15 hours by measuring secretion of IL-6 and IL-8, as well as surface expression of the adhesion molecules ICAM-1 and E-selectin. In addition, PS-DVB beads and cellulose sulphate beads were screened for the binding of HMGB1.

Results Adsorption of inflammatory mediators from the conditioned medium either with the specific TNFα adsorbent or with the selective PS-DVB beads resulted in decreased endothelial cell activation, as shown by statistically significant reduction of IL-6 and IL-8 secretion from HUVEC, as well as statistically significant reduction of surface expression of the adhesion molecules ICAM-1 and E-selectin. In the screening experiments, both PS-DVB beads and cellulose sulphate exhibited strong adsorption of HMGB1. Studies to test the effect of HMGB1 removal on endothelial activation in the cell culture model are underway.

Conclusions Inflammatory mediator modulation with specific or selective adsorbents reduces endothelial cell activation and thus may support the development of new therapies for sepsis. Hydrophobic PS-DVB resins as well as cellulose sulphate exhibit strong adsorption of HMGB1, a late mediator of sepsis.

Honokiol attenuates the severity of acute pancreatitis-associated lung injury by acceleration of acinar cell apoptosis
T Weng
National Taiwan University, Taipei, Taiwan

Introduction Acute pancreatitis (AP) is a complicated immunological response that leads to multiple organ failure. Apoptosis is a beneficial form of cell death in AP. Acute lung injury is the most severe complication. Honokiol (HK) is a component of Asian herbal teas. It displays an anti-inflammatory and apototic induction effect. In the experiments, we investigated the therapeutic efficacy of HK in AP.

Methods Adult BALB/c mice were divided into one control and five AP groups. Mice received six injections of cerulein at 1-hour intervals then above, but also received an i.p. of the different doses of HK 10 minutes after the first cerulein injection. Cytokine levels for the early and late inflammatory markers were obtained at 3 hours and 24 hours after the end of experiments.

Results HK protected against the severity of AP in serum amylase/lipase, TNFα, IL-6, HMGB1, and pancreas and lung pathological injury (Figure 1A). Acinar cell apoptosis was increased in the pancreas. Treatment with HK caused markedly increased acinar cell apoptosis (Figure 1B).

Conclusions HK attenuates the severity of AP and lung injury by acceleration of acinar cell apoptosis.

Reference
perfusion of the muscular and mucosal layers of the intestinal wall was significantly reduced (for example, longitudinalis muscular layer: \( \text{SHAM} 143.5 \pm 7.6 \, \text{cm/cm}^2 \); \( \text{CASP} 77.1 \pm 7.2 \, \text{cm/cm}^2 \)). Treatment of \( \text{CASP} \) animals with the \( \text{CB1} \) receptor agonist \( \text{ACEA} \) reduced leukocyte adhesion (V1 venules: 107.4 \pm 5.1 \, \text{n/mm}^2 \)), whereas \( \text{CB2} \) receptor stimulation did not affect leukocyte adhesion. However, \( \text{CB2} \) receptor inhibition by AM630 reduced leukocyte activation significantly (V1 venules: 60.0 \pm 14.1 \, \text{n/mm}^2 \) and restored capillary perfusion (longitudinal muscular layer: 114.1 \pm 7.6 \, \text{cm/cm}^2 \).

**Conclusions** The data suggest that ECS signaling is involved in the impairment of the intestinal microcirculation during sepsis. Blocking \( \text{CB2} \) receptor signaling reduces leukocyte activation and improves capillary perfusion in sepsis in rats. The long-term effect of ECS modulation needs further investigation.

**Desmopressin improves intestinal functional capillary density and decreases leukocyte activation in experimental endotoxemia in the rat**

L Wagner1, I Drzymulski1, D Pavlovic1, D Henzlers2, M Wendt1, C Lehmann2
1Greifswald University, Greifswald, Germany; 2Dalhousie University, Halifax, Canada

**Introduction** The vasopressin analogue desmopressin (DDAVP), a selective agonist of the vasopressin V2 receptor, is known to cause vasodilatation in addition to its haemostatic effects. To verify whether desmopressin could be beneficial in sepsis we investigated its effects on intestinal microcirculation in experimental endotoxemia in rats.

**Methods** In Lewis rats (six groups, 10 animals each) the effects of vasopressin (VAS) (0.06 U/340 g/minute) and DDAVP (1 μg/kg/ml) on the terminal ileum microcirculation 2 hours after introducing endotoxemia (5 mg/kg lipopolysaccharide (LPS), i.v.) were examined using intravital fluorescence microscopy.

**Results** Although desmopressin administration (DES-group) increased the number of rolling leukocytes in V3 venules (\( \text{P < 0.05 vs. CON-group} \)), the number of firmly adhering leukocytes in V1 venules of the LPS-group was significantly reduced (LPS-group: 259 \pm 25.7 vs. LPS+DES-group: 203 \pm 17.2 \, \text{n/mm}^2 \); \( \text{P < 0.05} \) (Figure 1). Additionally, DDAVP treatment improved impaired functional capillary density (FCD) following LPS in all examined intestinal layers (\( \text{P < 0.001 vs. LPS-group} \)), while the density of nonfunctional capillaries was significantly reduced (\( \text{P < 0.001 vs. LPS-group} \)). Vasopressin administration deteriorated FCD in endotoxemic and non-endotoxemic rats (\( \text{P < 0.05 vs. CON-group or LPS-group} \)). Three hours after LPS challenge, TNFα levels were significantly increased (\( \text{P < 0.05 vs. all controls} \)).

**Figure 1 (abstract P256).** Number of adherent leukocytes in venules (n/mm²). * \( \text{P < 0.001 for all LPS vs. all controls} \); # \( \text{P < 0.05 for LPS+DES vs. LPS} \).
reduced in both DDAVP-treated and vasopressin-treated LPS-groups (LPS-group: 429 ± 119; LPS+DES-group: 262 ± 21.9; LPS+VAS-group: 249 ± 46.5 pg/ml; P < 0.05).

Conclusions Desmopressin administration improved microvascular perfusion and reduced inflammatory response in experimental endotoxemia.

Hypoxic NO-donor nitrite protects sGC-dependently against morbidity and mortality associated with sterile inflammatory shock in mice
A Cauwels1, B Vandendriessche1, E Rogge1, S Shiva1, P Brouckaert1
1UGent & VIB, Gent, Belgium; 2University of Pittsburgh, PA, USA

Introduction For a long time nitrite (NO2⁻) was believed to be an inert metabolite of the endogenous vasodilator NO. Recently, however, nitrite was identified as an important biologic NO reservoir in vasculature and tissues, contributing to hypoxic signaling, vasodilation and cytoprotection after ischemia–reperfusion injury. Reduction of nitrite to NO may occur enzymatically at low pH and oxygen tension by deoxyhemoglobin or deoxymyoglobin, xanthine oxidase, mitochondria or NO synthase. Considering that NO may exert protective effects in inflammatory and septic shock, and that circulating nitrite may function as a source of NO in hypoxic and/or acidic conditions present in ischemic microvasculature of vital organs during shock, we decided to test the protective capacity of nitrite on toxicity associated with inflammatory shock.

Methods We studied sterile models of shock (induced by intravenous TNF or LPS) and a septic CLP model in female C57Bl/6 mice. NaNO2 treatments were done intravenously. To monitor morbidity, rectal body temperatures were measured and mortality was recorded. In addition, mice were sacrificed 2 or 6 hours after challenge to analyze serum markers for organ damage, as well as mitochondrial parameters, ATP production and infiltration of myeloid cells. Hemodynamic parameters were determined in conscious mice via radiotelemetry, using PA-C10 probes (Data Sciences International).

Results Low doses of nitrite significantly ameliorated hypothermia, organ damage and mortality induced by a lethal TNF challenge. Mechanistically, nitrite-dependent protection was associated with improved mitochondrial functioning, demonstrated by complex I, complex IV and aconitase activities in the liver and heart. In addition, nitrite protection was largely abolished in mice deficient for the α1-subunit of soluble guanylate cyclase (sGCα1), one of the principle intracellular NO receptors and signal transducers in the cardiovascular system. Interestingly, nitrite delayed and attenuated TNF-induced bradycardia and hypotension as well. In addition, higher doses of nitrite could also protect against toxicity induced by Gram-negative LPS, but not against mortality induced by CLP.

Conclusions We show that nitrite can protect against mitochondrial and organ damage in inflammatory sterile shock via sGC-dependent signaling. This may include hypoxic vasodilation, necessary to maintain microcirculation and organ function, as well as cardioprotection.

Interplay between the innate immune response and heart rate variability in healthy human volunteers
M Kox, BP Ramakers, JC Pompe, JG Van der Hoeven, CW Hoedemaekers, P Pickkers
Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands

Introduction The autonomic nervous system (ANS) and innate immunity are intimately linked. Heart rate variability (HRV) analysis is a widely employed method to assess cardiac ANS activity, and changes in HRV indices may correlate with inflammatory markers. Here, we investigated whether baseline HRV predicts the innate immune response.

Resultsdoi: 10.1186/cc9678

Figure 1 (abstract P258). Association between basal HRV indices (calculated at t = 0, just prior to LPS administration) and area under curve of the LPS-induced proinflammatory cytokine response (TNFα and IL-6, log pg/ml/hour) of 40 subjects. ms, milliseconds; AU, arbitrary units. Solid and dashed lines, TNFα and IL-6 regression lines, respectively. Pearson correlation coefficients (none statistically significant) indicated.
response. Second, we investigated whether the magnitude of the inflammatory response correlated with HRV alterations. **Methods** Forty healthy volunteers received a single intravenous bolus of 2 ng/kg endotoxin (lipopolysaccharide (LPS), derived from Escherichia coli O:113). Of these, 12 healthy volunteers were administered LPS again 2 weeks later. HRV was determined at baseline (just prior to LPS administration) and hourly thereafter until 8 hours post LPS. Plasma cytokine levels were determined at various time points. **Results** Baseline HRV indices did not correlate with the magnitude of the LPS-induced inflammatory response. Despite large alterations in HRV following LPS administration, the extent of the inflammatory response did not correlate with the magnitude of HRV changes. In subjects that were administered LPS twice, inflammatory cytokines were markedly attenuated following the second LPS administration, while LPS-induced HRV alterations were similar. See Figure 1. **Conclusions** HRV indices do not predict the innate immune response in a standardized model of systemic inflammation. The innate immune response results in HRV changes; however, no correlations with inflammatory cytokines were observed. These findings suggest that cardiac ANS activity may not reflect ANS outflow to other organs involved in the innate immune response. Furthermore, the magnitude of endotoxaemia-related HRV changes does not reflect the extent of the inflammatory response.

**Dysregulation of immune monocyte responses during sepsis**

D Fiome, G Caiazza, V Tisekulli, A Sinistro, C Almeighini, F Calo’-Carducci, E Baffani, A Bergamini, S Natioli, F Leonardi

Policlinico Roma Tor Vergata, ICU, Rome, Italy

**Critical Care 2011, 15(Suppl 1):**P259 (doi: 10.1186/cc9679)

**Introduction** Despite intense efforts, sepsis remains a serious clinical problem, accounting for thousands of deaths every year. Many findings have shown that immune dysfunction in septic patients plays a very important role. Thus, a better understanding of the basic immune alterations in sepsis is needed to appropriately direct therapy. Here we sequentially measured TNFα, IL-1ß, IL-6 and IL-10 de novo synthesis by monocytes via multiparametric flow cytometry and monocyte expression of surface molecules that allow effective antigen presentation, in patients with severe sepsis and septic shock up to 12 days after admission.

**Methods** Twenty-five patients and 15 healthy, age and sex matched control subjects were enrolled. Each patient met the following criteria: an identifiable site of infection; two or more systemic inflammatory response syndrome criteria. Septic shock was defined as severe hypotension that lasts 1 hour, despite adequate fluid resuscitation and pharmacologic intervention with vasopressor agents. Cell stimulation PBMC from patients and controls were cultured for 18 hours in the presence of 100 ng/ml LPS and analysed by FACS to determine cell surface antigen expression and intracellular cytokine production.

**Results** Cytokine production by monocytes during sepsis Monocytes from septic patients produced significantly higher amounts of IL-1ß, TNFα and IL-6, but not IL-10 as compared with controls. In addition, monocytes from patients with septic shock responded to LPS stimulation with increased IL-1ß, TNFα and IL-6 production with respect to cells from patients without septic shock. Serum cytokine levels All cytokines were readily detectable in septic patients. Effect of sepsis on surface molecule expression Monocyte CD80, CD86 and HLA-DR expression was significantly decreased in patients with sepsis as compared with healthy subjects. As opposed, the expression of ILT4 was significantly increased in septic patients as compared with healthy controls.

**Conclusions** It has been postulated that the immune response in sepsis represents the interplay of two contrasting phenomena: the early systemic inflammatory response syndrome followed by the late appearance of a compensatory anti-inflammatory response syndrome. The findings reported here suggest a scenario, characterized by the contemporary development of an intense proinflammatory reaction and a marked alteration of the phenotype of antigen-presenting cells.

**Different correlations between lymphocyte subsets from patients with intra-abdominal sepsis and pneumonia-derived sepsis**

T Skirecki, LZ Zielinska-Borkowska, MZ Zlotorowicz, JK Kawialk, GH Hoser

Medical Center of Postgraduate Education, Warsaw, Poland

**Critical Care 2011, 15(Suppl 1):**P260 (doi: 10.1186/cc9680)

**Introduction** Although there has been progress in understanding the immunopathology of sepsis, the mortality rates remain high and there is still a lack of effective immunomodulatory therapies. Possible reasons include heterogeneity of septic patients and inefficacy of methods of monitoring the immune system status [1]. Most of both the experimental and clinical studies do not distinguish sepsis based on the primary sites of infection. Therefore, we studied the differences in the cellular immune response during sepsis originating from pneumonia and peritonitis.

**Methods** Blood samples were obtained from 34 patients treated in our ICU in the first days of sepsis, severe sepsis or septic shock. Intra-abdominal sepsis (IAS) was diagnosed when SIRS symptoms with intra-abdominal, postoperative infection source occurred. Pneumonia-derived sepsis (PDS) diagnosis was based on SIRS accompanied by CXR lung consolidation. Samples were stained with the panel of antibodies against CD45, CD455, CD4, CD2, CD3, CD8, CD19, CD3, CD16, CD56 and isotypic control. Cells were analysed by flow cytometry and total cell count per microliter was calculated. Comparative and simple regression statistical analyses were performed.

**Results** Fourteen patients were diagnosed with IAS and eight with PDS. Etiology of most IAS was Gram-negative, while Gram-positive in PDS. The mortality rate was higher in PDS. Monocyte absolute number and white blood count were the only variables with statistically significant differences between IAS and PDS. The correlations between number of lymphocytes and monocytes, CD3+, CD4+ and CD19+ were high in both groups of patients. However, in IAS no correlation was found between the number of either cytotoxic CD8 lymphocytes and NK cells with lymphocyte count. Interestingly, a high correlation for the number of CD8+ and NK cells exists in both IAS and PDS patients.

**Conclusions** Our results indicate differences in the immune response during sepsis originating from respiratory and abdominal infections. Independent correlations between NK cells and cytotoxic lymphocytes suggest existence of shared mechanisms of their regulation.

**AZD9773 is a novel and potent anti-TNFα polyclonal ovine immune Fab**

P Newham, P Ceuppens, G Davies, J Growcott

AstraZeneca, Macclesfield, UK

**Critical Care 2011, 15(Suppl 1):**P261 (doi: 10.1186/cc9681)

**Introduction** The release of cytokines into the circulation is an essential part of the inflammatory cascade that underlies sepsis. Experimental and clinical data have shown that the proinflammatory cytokine TNFα is a principal mediator of this cascade [1-3]. The investigational drug AZD9773, intended for intravenous infusion, contains ovine immune fragments (Fabs) of IgG that bind to human (hu)-TNFα. Here we describe the in vitro and in vivo pharmacology of AZD9773.

**Methods** AZD9773 binding to human TNFα was assessed using surface plasmon resonance (SPR) technology. AZD9773 functional potency was profiled versus recombinant human (r-hu)-TNFα and natural (WHO International Standard) (n)-TNFα in TNFα-mediated cytotoxicity assays using the L929 cell line. Finally, humanised mice (Tg1278/TNF–/–: hu-TNFα transgenic, murine TNFα null) were used to assess AZD9773 effects on endotoxin-induced serum cytokines, chemokines and related factors.

**Results** SPR assays revealed that r-hu-TNFα bound to immobilised AZD9773 total Fabs with an equilibrium dissociation constant (K<sub>d</sub>) of ~60 nM. AZD9773 neutralised both r-hu-TNFα and n-TNFα biological activity in the L929 cytotoxicity assays. AZD9773 neutralised r-hu-TNFα with an apparent inhibitory constant (K<sub>i</sub>) of approximately 40 pM. In humanised mice, AZD9773 produced a statistically significant
reduction in 29 out of 60 serum cytokines and related factors (including hu-TNFα and murine IL-6).

Conclusions AZD9773 is a potent TNFα neutralising ovine immune Fab and, considering the modest AZD9773/TNFα binding affinity, these data indicate that there is significant synergy in neutralising TNFα bioactivity between the polyclonal anti-TNFα species that comprise AZD9773. The in vivo suppression of 29 out of 60 induced serum cytokines, chemokines and related factors confirms the significant role for TNFα in eliciting acute endothoxin responsiveness.

Results

Assessments included monitoring electrocardiogram outputs, heart rate and IL-6 production in cynomolgus monkeys. A mathematical (PK-PD) effects model was determined by the inhibition of endotoxin-induced TNFα release in vitro, with no unexpected binding to frozen primate tissue. The cytotoxicity assay using L929 cells, respectively. AZD9773 did not show any unexpected binding to frozen primate tissue. The in vivo ability of either AZD9773 or D-CytoFab to suppress TNFα-mediated effects was determined by the inhibition of endotoxin-induced TNFα and IL-6 production in cynomolgus monkeys. A mathematical (PK-PD) model was constructed to describe the cytokine PD profile. Safety assessments included monitoring electrocardiogram outputs, heart rate, blood pressure and toxicity indices in cynomolgus monkeys administered with AZD9773.

Results

There was no significant difference between AZD9773 and D-CytoFab in the binding of primate TNFα in vitro, and AZD9773 and D-CytoFab neutralised recombinant primate TNFα with a two-fold and 1.8-fold reduction in potency, respectively, with recombinant human TNFα. Both AZD9773 and D-CytoFab at equivalent doses with comparable exposure significantly suppressed endotoxin-induced IL-6 production in cynomolgus monkeys to a similar extent. PK-PD analysis revealed the effect of AZD9773 and D-CytoFab on serum TNFα and IL-6 levels and estimated model parameters were not significantly different. No toxicologically significant findings were observed in cynomolgus monkeys with AZD9773 at doses significantly higher than those currently under clinical investigation.

Conclusions

Preclinical data indicate that AZD9773 has a good safety profile and is a well-tolerated anti-TNFα immune Fab product with PD characteristics similar to D-CytoFab.

5AstraZeneca, Wilmington, DE, USA; 6Vanderbilt University, Nashville, TN, USA

Introduction

Sepsis remains a significant medical problem. TNFα is a central cytokine in sepsis pathophysiology. We conducted a phase IIa trial in patients with severe sepsis to assess the safety and tolerability of an intravenously infused ovine-derived polyclonal anti-TNFα Fab fragment (AZD9773).

Methods

This was a double-blind, placebo-controlled, dose-escalation trial (NCT00615017) with 2:1 randomisation (active:placebo). Two single-dose cohorts (50 units/kg and 250 units/kg) and three multiple-dose cohorts (250 units/kg followed by nine doses of 50 units/kg every 12 hours, 500 units/kg followed by nine doses of 100 units/kg, 750 units/kg followed by nine doses of 250 units/kg) were studied. Safety was assessed by monitoring adverse events (AEs), mortality, and laboratory safety measures, including formation of human anti-sheep antibodies (HASA) and their association with AEs.

Results

A total of 70 patients were studied. The mean age was 56 years, 46% were male, and the mean APACHE II score was 26. About 50% of patients had two organ failures (both respiratory and cardiovascular). Multiple doses of AZD9773 reduced circulating TNFα towards the limit of detection in most patients throughout the 5 days of dosing. The most common serious AEs were mainly related to the underlying illness and included: sepsis, pneumonia, septic shock and respiratory failure across all groups. Table 1 summarises the safety outcomes. Development of HASA did not appear to be associated with either decreased TNFα reduction or specific AEs.

Conclusions

Administration of AZD9773 in patients with severe sepsis reduced circulating TNFα levels and had a safety profile similar to placebo administration. A larger randomised phase IIb clinical trial (NCT01145560) is ongoing to further characterise the safety and efficacy of AZD9773 in patients with severe sepsis.

Evaluation of eritoran tetrasodium (E5564), a TLR4 antagonist, on the QTc interval in healthy subjects

CF Nagy, M Lynn, J Gogate

Eisa, Inc, Woodcliff Lake, NJ, USA

Introduction

Eritoran tetrasodium (E), a TLR4 antagonist, is currently being evaluated in phase 3 as a treatment for severe sepsis and has been well tolerated in clinical trials [1]. The primary objective of this study was to evaluate the effect of E on QTc in healthy subjects.

Methods

This was a single 12-hour intravenous infusion, double-blind, placebo-comparator and active-comparator controlled, parallel-group
P265

Safety, pharmacokinetics, and pharmacodynamics of 4-hour intravenous infusion of eritoran tetrasodium in healthy Japanese and Caucasian males

1Eisai, Inc., Woodcliff Lake, NJ, USA; 2Emergency and Critical Care Medicine, School of Medicine, Keio University, Tokyo, Japan; 3Eisai, Inc., Andover, MA, USA; 4Eisai Co., Ltd, Tokyo, Japan; 5The University of British Columbia, Vancouver, Canada

Introduction

Activation of TLR4 signaling by endotoxin is believed to be a primary mediator of sepsis and septic shock, via excessive production of cytokines and proinflammatory mediators [1]. Eritoran tetrasodium (hereafter eritoran), a synthetic analog of the endotoxin constituent lipid A, binds to the TLR4/MD-2 complex and thereby blocks the interaction of endotoxin with TLR4 [2]. Eritoran is being investigated for the treatment of severe sepsis [3]. We report results of a study conducted to assess the single-dose safety and tolerability, as well as pharmacokinetics and pharmacodynamics, of eritoran infusion in Japanese and Caucasian healthy adult males.

Methods

This was a double-blind, randomized, single-center, placebo-controlled, ascending single-dose, sequential-group study. Sixty-four subjects (aged 20 to 45 years; BMI 18 to 30 kg/m^2) were randomized to four groups: 4 mg total dose (n = 12); 12 mg total dose (n = 24); 28 mg total dose (n = 12); placebo (n = 16). Adverse events were recorded by the investigator. Laboratory assessments included standard hematology and clinical chemistry, lipid analysis, and urinalysis.

Results

There were no serious adverse events. Eritoran in single doses up to 28 mg over 4 hours was well tolerated, with no apparent ethnic differences noted. Plasma concentrations were slightly higher, while clearance and volume of distribution were lower, in Japanese versus Caucasian subjects; these differences were not significant after adjustment for differences in body weight. The ex vivo endotoxin inhibitory activity of eritoran was similar in Japanese and Caucasian subjects. Eritoran was distributed mainly to the HDL fraction in both Japanese and Caucasian subjects.

Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands

Introduction

Previous studies have shown that the endogenous nucleoside adenosine is able to modulate inflammation and to prevent associated organ injury. Dipyridamole, an adenosine uptake inhibitor, increases extracellular adenosine concentrations during unfavorable conditions (for example, inflammation), and as such may modulate the inflammatory response. We examined the effects of dipyridamole treatment on innate immunity during human experimental endotoxemia.

Methods

In a randomized double-blind placebo-controlled study, 20 healthy subjects received 2 ng/kg Escherichia coli endotoxin

Figure 1 (abstract P266). Cytokine response following endotoxemia.
intravenously following 7-day pretreatment with dipyridamole, 200 mg retard twice daily, or placebo.

**Results** Nucleoside transporter activity was significantly reduced by dipyridamole treatment with 89 ± 2% (P < 0.0001) and resulted in significantly augmented endogenous adenosine levels. Plasma concentrations of dipyridamole correlated with the peak adenosine concentration 2 hours after LPS administration (r = 0.82, P = 0.0038) and significantly augmented the anti-inflammatory IL-10 response during endotoxaemia (P < 0.0001; Figure 1), an effect that correlated with the dipyridamole-induced increase in adenosine (r = 0.82; P = 0.0035).

Finally, IL-10 peak concentrations were associated with a more pronounced decline in TNFa (r = 0.54, P = 0.018).

**Conclusions** Dipyridamole treatment increases adenosine concentrations during systemic inflammation associated with an augmented anti-inflammatory response and a faster decline in TNFa during human experimental endotoxaemia.

Use of statins in community-acquired pneumonia in intensive care settings: is there a survival advantage?

A Khanna, R Gibbs, S Webster, H Al-shather
Musgrove Park Hospital, Somerset, UK

**Introduction** Use of statins in community-acquired pneumonia (CAP) and exacerbation of COPD has been widely studied [1-3]. Whilst there may be some outcome benefit with the use of statins in exacerbation of COPD, their role in CAP remains less clear. There are no studies looking at outcome benefits from statin use in patients with CAP who are admitted to the intensive therapy unit (ITU). Therefore, we conducted a retrospective cohort analysis looking at statin use and outcomes in patients with CAP admitted to our ITU.

**Methods** We retrospectively analysed 200 consecutive admissions to our ITU who had an admission diagnosis of CAP. Use of statins in those diagnosed with CAP was determined and its relation to length of stay and in-patient mortality was assessed. Baseline patient characteristics, disease severity scores, dose and type of statin prescribed were also considered.

**Results** Out of the total 200 patients with a coded diagnosis of CAP, 108 patients (54%) had CAP on notes review. Statins were prescribed in 43 (39.8%) of these patients. Statins were prescribed more often in patients >65 years old. Baseline characteristics were similar in both groups (>60 years: 62% vs. 65%, P = 0.7; CURB 65 2 to 3: 48% vs. 50%, P = 0.8; APACHE I <10: 16% vs. 20%, P = 0.5; APACHE II 10 to 20: 43% vs. 42%, P = 1.00; APACHE II >20: 41 vs. 38, P = 0.7). The male:female ratio in our cohort was 1:1.3 (43% vs. 57%). Overall, in-hospital mortality in this CAP cohort was 45% (n = 48). This was higher than the previously reported studies [4]. We believe this represents the higher average age of the population with more accumulated co-morbidities that we cater for. Simvastatin was the most commonly prescribed statin (66% patients) in varying dosages (10 to 80 mg OD). There was no statistically significant difference in mortality between those who received statins and those who did not (55% vs. 47%, P = 0.29). Length of stay amongst survivors was similar in both groups (<7 days: 58% vs. 61%, P = 0.7; 7 to 14 days: 39% vs. 33%, P = 0.4; >14 days: 3% vs. 6%, P = 0.4).

**Conclusions** According to this retrospective cohort study, use of statins in patients admitted to the ITU with a diagnosis of community-acquired pneumonia does not seem to provide any statistically significant survival benefit. Also, there seems to be no benefit in terms of total length of stay amongst survivors.

Atorvastatin for preventing the progression of sepsis to severe sepsis (ASEPSIS Trial): a randomised, double-blind, placebo-controlled trial (ISRCTN64637517)

JM Patel, C Snarth, D Thickett, L Linhortova, T Melody, P Hawkey, T Barnett, A Jones, T Hong, G Perkins, M Cooke, F Gao-Smith
Heart of England NHS Foundation Trust, Birmingham, UK

**Introduction** Statins have pleiotropic effects independent of their lipid-lowering properties and may modulate the pathophysiology of sepsis, prevent sepsis progression and improve outcomes [1]. This study evaluated the acute use of Atorvastatin in reducing sepsis progression compared with placebo in statin-naïve individuals.

**Methods** A single-centre, randomised placebo-controlled, double-blind trial (RCT). Ethical approval and consents were obtained. Patients with sepsis, based on the Surviving Sepsis Campaign Guidelines (SSCG), were randomised to Atorvastatin 40 mg daily or placebo for length of hospital stay or 28 days if earlier. Patients on statins were excluded. Primary outcome was progression to severe sepsis, defined by the SSCG.

**Results** One hundred patients were consented and randomised, 49 to Atorvastatin and 51 to placebo. Both were well matched for all baseline characteristics. The Atorvastatin group had a lower rate of sepsis progression P = 0.007 (Figure 1). The 28-day and 1-year mortalities were similar with an overall 12% mortality. There was no difference in 28-day readmissions (P = 0.83); however, 1-year readmissions were higher in the placebo group (P < 0.001). A rise in matrix metalloproteinase 9 (P = 0.01) at day 4 was observed in the Atorvastatin group.

**Figure 1 (abstract P268). Percentage of patients progressing to severe sepsis (%).

**Conclusions** This is the first RCT to show that the acute use of Atorvastatin can prevent sepsis progression in statin-naïve individuals. A multicentre RCT is required to elucidate the mechanisms and clinical applications of these findings.

Kinetics of immunoglobulins in septic shock patients

C Sierra, C David, C David
University Hospital, Rio de Janeiro, Brazil

**Introduction** The mechanisms of sepsis are not understood in all aspects. We decided to measure the IgG and IgM serum level in these patients and tried to correlate our results with the mortality rate and also to establish the medium time in the blood of these immunoglobulins.

**Figure 1 (abstract P269). Percentage of patients progressing to severe sepsis (%).
Methods We selected patients according to the Bonne and colleagues classification of septic shock. As soon as the patients were selected we took samples at four time points (day 1, day 2, day 3, and day 7). We measured the serum level of IgG and IgM of all patients. There were 189 patients studied from 360 with septic shock. We excluded 171 patients for three reasons: they were neutropenic, had transfusions for <1 month or had recently undergone chemotherapy. Septic patients represented 17% of all patients in the ICU.

Results From these 189 selected patients we had a mortality rate of 59 patients, which amounts 31%. From these patients 29 had combined deficiency of IgG and IgM levels, 17 had only IgG deficiency and 13 had IgM deficiency. We considered a deficient value as levels less than the minimum level for immunoglobulins according to our nephelometry measurement.

Conclusions Despite the fact that we had a small number of patients we can conclude that these measurements could be considered good prognostic markers, not only in terms of mortality rate but also to demonstrate that IgG and IgM levels do not have the 21 and 7 days of medium time in the circulation we can see in normal patients. Probably in the near future we could include immunoglobulin determination on a routine basis for septic shock patients.

P270 Whole blood lactate kinetics in patients undergoing quantitative resuscitation for septic shock

MA Puskarich,1 S Trzeciak,1 N Shaprio1, A Heffner1, JA Kline1, AE Jones1
1. Camden, NJ, USA; 2. Beth Israel Deaconess Medical Center, Boston, MA, USA

Introduction We sought to compare the association of whole blood lactate kinetics with survival in patients with septic shock undergoing early quantitative resuscitation.

Methods Preplanned analysis of a multicenter emergency department (ED)-based randomized control trial of early sepsis resuscitation targeting three physiological variables: central venous pressure, mean arterial pressure, and either central venous oxygen saturation or lactate clearance. Inclusion criteria: suspected infection, two or more systemic inflammatory response syndrome criteria, and either SBP <90 mmHg after a fluid bolus or lactate >4 mmol/l. All patients had a lactate measured initially and subsequently at two hours. Normalization of lactate was defined as a lactate decline to <2.0 mmol/l in a patient with an initial lactate ≥2.0. Absolute lactate clearance (initial – delayed value), and relative (absolute clearance) / (initial value) x 100 were calculated if the initial lactate was ≥2.0. The primary outcome was in-hospital survival. Receiver operating characteristic (ROC) curves were constructed and the area under the curve (AUC) was calculated. Differences in proportions of survival between the two groups at different lactate cutoffs were analyzed using 95% confidence intervals and Fisher exact tests.

Results Of 272 included patients, median initial lactate was 3.1 mmol/l (IQR 1.7, 5.8), and median absolute and relative lactate clearance were 1 mmol/l (IQR 0.3, 2.5) and 37% (IQR 14, 57). An initial lactate >2.0 mmol/l was seen in 187/272 (69%), and 68/187 (36%) patients normalized their lactate. Overall mortality was 19.7%. AUCs for initial lactate, relative lactate clearance, and absolute lactate clearance were 0.70, 0.69, and 0.58, respectively. Lactate normalization best predicted survival (OR = 6.1, 95% CI = 2.2 to 21), followed by lactate clearance of 50% (OR = 4.3, 95% CI = 1.8 to 10.3), initial lactate of <2 mmol/l (OR = 3.4, 95% CI = 1.5 to 7.8), and initial lactate <4 mmol/l (OR = 2.3, 95% CI = 1.3 to 4.3), with lactate clearance of 10% not reaching significance (OR = 2.3, 95% CI = 0.96 to 5.6).

Conclusions In ED sepsis patients undergoing early quantitative resuscitation, normalization of serum lactate during resuscitation was more strongly associated with survival than any absolute value or absolute/relative change in lactate. Further studies should address whether strategies targeting lactate normalization leads to improved outcomes.

P271 Plasma DNA concentration as an early predictor of outcome in critically ill septic patients

H El-Akabawy, W Radwan, S Gengeehy, A Rezk, A Sisi
Cairo University, Cairo, Egypt

Introduction Sepsis is associated with cell necrosis and apoptosis. Indeed, plasma DNA levels have been shown to be increased in patients with sepsis [1]. So we investigated the prognostic value of circulating levels of cell-free DNA in critically ill septic patients regarding the clinical course and final outcome.

Methods A total of 80 critically ill septic patients were included in a prospective, randomized, single-center study. All were subjected to the measurement of cell-free plasma DNA concentrations (by real-time PCR assay for the β-globin gene), CRP levels and procalcitonin concentrations, all measured on ICU admission. APACHE II and SOFA scores were calculated. Clinical outcome (duration of ICU stay, need for MV, need for inotropic/vasopressor support, need for haemodialysis, and final outcome of survival/mortality rates) were recorded for all patients.

Results The median plasma DNA concentration in critically ill septic patients was 195.7 ng/ml and this was significantly (approximately sevenfold) higher than the DNA concentration in healthy subjects (27 ng/ml (P < 0.001). The median DNA concentration was significantly higher in those who need MV (205.6 ng/ml vs. 123.7 ng/ml; P = 0.006), in those who were on inotropic/vasopressor support (234.6 ng/ml vs. 114.7 ng/ml; P < 0.001) and in those who required renal supportive therapy (haemodialysis) (244.2 ng/ml vs. 181.1 ng/ml; P = 0.001). DNA concentration demonstrated a highly significant correlation with CRP concentration (r = 0.661, P < 0.001), procalcitonin concentration (r = 0.820, P < 0.001), SOFA score (r = 0.710, P < 0.001), and APACHE II score (r = 0.539, P < 0.001). The median plasma DNA concentration in nonsurvivors (38 of 80 patients, 47.5%) was 234.8 ng/ml and this was significantly (approximately twofold) higher than in survivors (115.5 ng/ml; P < 0.001). Receiver operator characteristic analysis of the data indicated a sensitivity of 95% and a specificity of 81% when DNA concentration of 186.5 ng/ml was taken as a predictor of ICU mortality.

Conclusions Plasma cell-free DNA may be a potentially useful marker for the evaluation of ICU septic patients and for the prediction of their adverse outcomes. The ability for rapid risk stratification may allow clinicians to make more rational therapeutic decisions to ensure that the hospital resources are used efficiently and appropriately.

P272 C-reactive protein as an early marker of sepsis resolution: results from the Portuguese Community-acquired Sepsis Study (SACIUCI study)

P Povoa1, A Teixeira-Pinto1, A Carneiro1
1. Hospital Sao Francisco Xavier, CHU, Lisboa, Portugal; 2. Faculty of Medicine, University of Porto, Portugal; 3. Hospital Santo Antonio, Porto, Portugal

Introduction To assess the value of C-reactive protein (CRP) after prescription of antibiotics in order to define clinical resolution of community-acquired sepsis (CAS) admitted to the ICU.

Methods During 12 months a cohort multiple-centre observational study was conducted in 17 Portuguese ICUs segregating adults with CAS consecutively admitted. Patients were followed-up during the first 5 ICU days, the day of ICU discharge or death and hospital outcome. Comparison between survivors and nonsurvivors was performed.

Results Eight hundred and ninety-one patients (age 60 ± 17 years, hospital mortality 38%) were studied. At D1, CRP of survivors and nonsurvivors was not statistically different, 19.8 ± 12.5 mg/dl vs. 20.7 ± 12.8 mg/dl (P = 0.367). When we compared CRP of survivors and nonsurvivors at the different time points, we found that CRP of nonsurvivors was significantly higher since D3 onwards (P < 0.001, for D3, D4 and D5). After adjusting for SAPS II and severity of sepsis...
(sepsis, severe sepsis and septic shock), the initial value of CRP was not significantly associated with hospital mortality (OR was 1.01, 95% CI = (0.99, 1.02), P = 0.297). On the other side, the course of CRP measured as the relative change, obtained from a patient's specific linear model for the 5-day measurement of CRP generated two new variables, an intercept (describes the initial CRP value) and a slope (describes the CRP rate of change per day for a specific patient). We found that the slope was significantly associated with hospital mortality (OR CPR ratio = 1.03, 95% CI = (1.02, 1.04), P < 0.001). A patient with an average decrease of the CRP concentration of 10% per day has 3.2% less chance of dying when compared with a patient with the same SAPS II and the same severity of sepsis but with no decrease of the CRP. The area under the ROC curve for the model including SAPS II, severity of sepsis, initial CRP and CRP course, was 0.77. No significant differences between survivors and nonsurvivors were found on daily monitoring of temperature and white cell count, both at the first day (P = 0.799 and P = 0.496, respectively) and in the course of subsequent days (P = 0.360 and P = 0.594, respectively).

Conclusions Daily CRP measurement after antibiotic prescription was useful in identification, as early as day 3, of CAS patients with poor outcome. The slope of CRP course was markedly associated with prognosis.

Prognostic value of routinely assessed serum biomarkers in septic shock

E Lafuente, E Viegas, E Filipé, E Tomás, M Fernandes, I Gomes da Silva, F Santos, F Moura, R Lopes, P Santos, N Ribeiro, I Terra
Centro Hospitalar Tamega e Sousa, Penafiel, Portugal

Introduction The objective of this study was to assess the usefulness of routinely admission measured biomarkers.

Methods From a sample of 256 patients enrolled between October 2009 and November 2010, 193 had sepsis and 63 had septic shock based on the ACCP/SCCM criteria, and for each of them we measured reactive protein C (RCP), total cholesterol, protein C activity (PC), albumin, arterial lactate and the levels of IL-6 at admission.

Results Levels of lactate, IL-6 and PC (<40%) showed the best accuracy for prediction mortality in all of the study patients as much as in the arm of the septic shock patients (AUROC 0.76; 0.80; 0.75, respectively; and AUROC 0.86; 0.86; 0.75, respectively). See Table 1.

N-terminal pro-BNP predicts mortality better than procalcitonin in abdominal severe sepsis and septic shock

N Ruiz-Vera, MJ Antolino-Martinez, A Gonzalez-Lisorgé, C Garcia-Palenciano, T Sansano-Sanchez, F Acosta-Villegas
1University Hospital, Murcia, Spain; 2University Hospital Virgen de la Arrixaca, Murcia, Spain

Introduction N-terminal pro-BNP (pBNP) could be useful to predict outcome in severe sepsis. We have conducted a study to compare pBNP and procalcitonin (PCT) in the setting of abdominal severe sepsis or septic shock.

Methods We performed a prospective study of 51 consecutive patients with abdominal severe sepsis or septic shock. Age, gender, APACHE II score at admission, in-unit survival, presence of septic shock and serum PCT and pBNP levels during 4 days after admission were determined. Statistics: chi-square test, Student’s t test, Mann–Whitney’s test for samples without normal distribution and Cox’s logistic regression. P <0.05 was considered statistically significant.

Results The mean APACHE II score at admission was 20.52 ± 5.07. This value was found to be significantly higher in nonsurvivors (18.38 ± 4.56 vs. 24.00 ± 4.03, P <0.05). Values of pBNP were significantly higher in nonsurvivors from the first day of the study. PCT levels were higher in nonsurvivors, but only reached statistically significance on day 2 (Table 1). These results were not found to be influenced by age, gender or presence of shock in multivariate analysis.

P276 Prognostic value of proadrenomedullin in severe sepsis and septic shock patients with community-acquired pneumonia
B Suberviola, A Castellanos, L García Astudillo, D Iglesias, F Ortiz Melon
University Hospital Marques de Valdecilla, Santander, Spain

Introduction Community-acquired pneumonia (CAP) is the leading cause of death from infectious disease in western countries and supposes an important consumption of healthcare resources. Several studies suggest that proADM is possibly as good as validated severity scores in detecting critically ill patients with CAP and probably better than other biomarkers like procalcitonin (PCT).

Methods A single-centre prospective study between January 2009 and September 2009. Eligible patients were all consecutive adult patients, age 17 or older, admitted to the ICU with both a clinical and radiologic diagnosis of pneumonia as per Fine and colleagues, and meeting criteria for severe sepsis or septic shock. Venous blood samples were obtained at admission on the ICU and collected in tubes containing EDTA. After centrifugation, they were kept frozen at –80°C until assayed. MR-proADM, PCT and C-reactive protein (CRP) were measured in these samples.

Results In all cases, proADM values at ICU admission were pathological. ProADM consistently rose as PSI class advanced from II to V (P = 0.02). Differences across PSI class were not significant for CRP (P = 0.73) and PCT (P = 0.12). Median proADM levels were higher (P = 0.007) in hospital nonsurvivors (8.1 ± 9.2 nmol/l) versus survivors (3.0 ± 3.2 nmol/l). The results were also significant with respect to ICU mortality (9.9 ± 10.4 vs. 3.2 ± 3.2 nmol/l; P = 0.001). The receiver-operating characteristic curve for proADM yielded an AUC of 0.72; better than the AUC for PCT and CRP (0.40 and 0.44, respectively) and similar to PSI (0.74). The optimal prognostic cut-off (maximum combined sensitivity and specificity) related to in-hospital mortality for proADM was 4.86 nmol/l, with a sensitivity of 0.53, specificity of 0.84, positive likelihood ratio of 3.39, negative likelihood ratio of 0.56, positive predictive value of 64.3 and negative predictive value of 77.1. Those patients with a proADM level higher than 4.86 nmol/l on ICU admission had an in-hospital mortality significantly higher than those with lower value.

Conclusions ProADM levels on ICU admission predict the severity and outcome of severe sepsis and septic shock CAP with a similar prognostic accuracy as the PSI and a higher prognostic accuracy compared with commonly measured laboratory parameters.

P277 Influence of TIMP-1/MMP-9 ratio on the severity and mortality in sepsis
L Lorente1, MM Martín2, J Solé-Violán3, J Blanquer1, L Labarta4, C Díaz5, JM Borreguero-León6, JA Páramo3
1 Hospital Universitario de Canarias, La Laguna, Spain; 2 Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain; 3 Hospital Universitario Dr Negrín, Las Palmas de Gran Canaria, Spain; 4 Hospital Clínico Universitario de Valencia, Spain; 5 Hospital San Jorge, Huesca, Spain; 6 Hospital Insular, Las Palmas de Gran Canaria, Spain; 7 CIMA-Universidad de Navarra, Pamplona, Spain

Introduction The role of matrix metalloproteinases (MMPs) and tissue inhibitors of matrix metalloproteinases (TIMPs) in sepsis remains unclear. MMPs play a role facilitating the recruitment of leucocytes from the bloodstream (by proteolysis of the basement membrane) and modulating inflammatory response [1]. Besides, there has been reported a positive association between circulating levels of TIMP-1 and plasminogen activator inhibitor (PAI)-1 in healthy adults [2] and myocardial infarction [3]. In addition there are in vitro studies showing that MMP-9 inhibits platelet aggregation [4,5]. Thus a high TIMP-1/MMP-9 ratio could contribute to a prothrombotic state, and the development of organ dysfunction and finally death in septic patients. The objectives of this study were to investigate the time course of MMP-9, MMP-10 and TIMP-1 levels, and the association with sepsis severity and PAI-1 levels.

Methods This was a multicenter, observational and prospective study carried out in six Spanish ICUs. We included 192 (125 surviving and 67 nonsurviving) patients with severe sepsis. We obtained blood samples at three moments (time of diagnosis, 72 hours and 7 days) for the determination of MMP-9, TIMP-1, TNFα, IL-10 and PAI-1 levels. We assessed survival at 30 days as the endpoint.

Results Nonsurvivor patients showed at the three moments lower MMP-9 levels, higher TIMP-1 levels and higher TIMP-1/MMP-9 ratios than survivors. There were at the three moments an association of the TIMP-1/MMP-9 ratio with lactic acid levels, SOFA score, PAI-1 levels, TNFα and IL-10. Logistic regression analysis showed that TIMP-1 levels, lactic acid levels and SOFA score were associated with death at 30 days.

Conclusions To our knowledge, this study includes the largest series reporting data on MMP levels in sepsis. The novel findings of our study are that nonsurviving septic patients showed a persistent higher TIMP-1/MMP-9 ratio than survivors during the first week than survivors. From a therapeutic perspective, the development of modulators of MMP/TIMP activity could be used as a new class of drugs for the treatment of severe sepsis.

Impact of pro-domain stability of matrix metalloproteinase-8 on the outcome of sepsis

1McLaughlin1, J Belcaro1, A Bakani1, L Kong1, L Zhu1, D Frederick1, S Yende1, R Ferrell1, I Bahar1, S Shapiro1, D Angus1, A Kaynar1
1University of Pittsburgh, PA, USA; 2University of Vienna, Austria; 3University of Tulane, New Orleans, LA, USA

Introduction Animal studies suggest matrix metalloproteinase-8 (MMP8) (neutrophil collagenase) impairs neutrophil (PMN) recruitment in inflammation; in humans, MMP8 has been associated with inflammation. We hypothesized that septic patients with single nucleotide polymorphisms (SNPs) in the MMP8 promoter region will have a survival advantage, and this advantage is due to differences in MMP8 enzymatic activity and not MMP8 levels.

Methods We examined data from patients with CAP-associated sepsis (GenIMS), analyzed three functional SNPs (rs3765620, rs1940475, rs11225395) in 1,567 Caucasians and tested associations with 60-day and 90-day mortality and severe sepsis incidence. We simulated functional MMP8 SNPs using anisotropic network modeling. Modeling suggested pro-domain structural stability affecting zymogen activation. Based upon this study and simulations, we then studied zymogen activation using bioluminescent resonance energy transfer (BRET). We generated recombinant pro-MMP8 with a pro-domain tag of luciferase and carboxy terminus tag of green fluorescent protein. BRET signal was generated when luciferase-cleaved substrate produced a photon transferring energy to the GFP acceptor. GFP in turn emitted a green light signal when the donor/acceptor pairs were spatially close. Upon MMP activation, pro-domain is cleared causing a loss in BRET signal.

Results The rs1940475 genotype causing an amino acid mutation in the pro-domain was significantly associated with 90-day mortality (AA: 8.3%, AG: 11.1%, GG: 14.7%, P = 0.007). Cumulative incidence showed that the A allele was associated with better 90-day survival. Computer simulation of the mutation suggests a delayed activation. BRET assay confirmed that pro-domain mutation of MMP8 (K87E) rendered it less amenable to activation.

Conclusions Our results suggest altering the structural stability of the inhibitory MMP8 pro-domain impacts enzyme activation. Therapeutics targeting pro-domain could be used to modulate MMP function and control downstream inflammatory processes in sepsis.

Increased levels of soluble triggering receptor expressed on myeloid cells sTREM1 in ICU patients with cardiovascular disease and associated organ dysfunction

S Dewan, A Varma, M Talegaonkar
Fortis Escorts Heart Institute, New Delhi, India

Introduction sTREM1, a new receptor of the immunoglobulin superfamily, is expressed on neutrophils and monocytes/macrophages. It has been reported to be a useful marker in infectious inflammatory conditions such as sepsis, pneumonia and pancreatitis. Cardiovascular disease with shock and associated organ dysfunction in the form of acute kidney injury (AKI) and acute liver damage (LD) is a unique subset of disease conditions mediated by the inflammatory process and there may be a role of sTREM1 levels in assessing the severity of disease and prognostication of the patient. We hypothesized that the sTREM1 level may be increased in patients with cardiovascular disease and organ dysfunction and it can be used as a prognostic marker.

Methods A retrospective analysis of sTREM1 levels of 139 (99 males, 40 females) (P < 0.004) patients admitted between October 2009 and January 2010 to the ICU of our hospital. Patients with cardiovascular disease and organ dysfunction like AKI and LD were analysed. sTREM1 level > 25 pg/ml was taken as abnormal.

Results A total of 139 patients were analysed. sTREM1 was abnormal in 82 (59%) of the patients (mean ± SD 63.26 ± 54.58) and normal in 57 (41%) patients (15.36 ± 6.10), which is highly significant (P < 0.0001) and correlates well with total leucocyte counts, which are (mean ± SD) 15,283 ± 6,126 for patients with abnormal sTREM1 and 13,001 ± 6,518 for normal patients (P < 0.05). Out of 75 patients with coronary artery disease (CAD), 50 (61%) patients had abnormal sTREM1 levels as compared with 25 (43.9%) with normal levels (P < 0.046). Out of 18 patients with AKI, 15 (83.3%) had abnormal sTREM1 levels and three (16.6%) had normal levels (P < 0.020). Out of 15 patients with LD, 13 (84.1%) had abnormal value and two (15.9%) had normal levels (P < 0.017). Although patients with abnormal sTREM1 had higher mortality it was not statistically significant due to the small number of patients.

Conclusions sTREM1 levels rise significantly in all kinds of cardiovascular disease and associated organ dysfunction like AKI and LD. Abnormal levels are also related to higher mortality, although not statistically significantly. The level of sTREM1 can be used as a prognostic marker for patients with this kind of disease scenario. These results confirm the usefulness of sTREM1 as a biological marker for diagnosing the severity of disease.

**P281** Bronchoalveolar lavage/blood ratio of surface TREM-1 on CD14-positive monocytes is diagnostic of ventilator-associated pneumonia

V Grover1, P Kellerer1, D Henderson2, P Pantelidis1, F Gotch1, N Soni1, S Singh1

1Chelsea and Westminster NHS Foundation Trust, London, UK; 2Imperial College Healthcare NHS Trust, London, UK

**Introduction** Biomarkers offer the possibility to speed up diagnosis of ventilator-associated pneumonia (VAP) and differentiate it from nonpulmonary infection. One such marker, the triggering receptor expressed on myeloid cells-1 (TREM-1), exists as a soluble protein and a surface receptor expressed on monocytes and neutrophils [1]. The purpose of the study was to determine the diagnostic utility of surface TREM-1 levels in VAP.

**Methods** Paired bronchoalveolar lavage (BAL) and blood were obtained from 25 VAP patients, 15 ventilated non-infected controls, 10 ventilated patients with nonpulmonary infection and 25 nonventilated controls. VAP diagnosis was by clinical pulmonary infection score (CPIS) and semiquantitative microbiology. BAL and blood monocytic and neutrophilic levels of surface TREM-1 and CD11b (leukocyte activation marker) were assessed using flow cytometry. Monocytes were CD14-positive. Soluble TREM-1, IL-1β, IL-6 and IL-8 were measured using ELISA. BAL dilution was corrected by urea assay.

**Results** See Figure 1. The BAL level of monocytic surface TREM-1 was elevated in VAP. For ventilated patients, the area under the ROC curve (AUC) was 0.87 for diagnosing VAP, with sensitivity 72% and specificity 80%. Blood levels did not differ between the groups. However, the BAL/blood ratio improved diagnostic accuracy further. The AUC was 0.97, sensitivity 84%, specificity 92% and positive likelihood ratio 10.5. The ratio differentiated pulmonary from nonpulmonary infection. The BAL/blood ratio of monocytic CD11b was 0.78. The BAL levels of neutrophil surface TREM-1, soluble TREM-1, IL-1β and IL-8 had AUCs of 0.75, 0.76, 0.81 and 0.85, respectively.

**Conclusions** The BAL/blood ratio of monocytic surface TREM-1 diagnoses VAP and differentiates pulmonary from nonpulmonary infection. CD14 and TREM-1 may have a role in the pathogenesis of VAP.

**Introduction** Several studies of critically ill patients have suggested an association of the D/D genotype of the insertion/deletion (I/D) angiotensin-converting enzyme (ACE) polymorphism with poor outcome probably by enhancing the inflammatory response and leading to a procoagulant state. Our aim was to evaluate the effect of both the ACE I/D polymorphism and its gene product, on the clinical outcome of critically ill septic patients.

**Methods** The study cohort included 186 consecutive Caucasian patients with sepsis, severe sepsis or septic shock. Epidemiological, clinical data and co-morbidities along with severity scores were recorded. Measurements of serum ACE activity and genotyping for ACE I/D polymorphism were carried out in all patients. The primary outcomes included the number of days without renal or cardiovascular failure, and ventilation-free days over the 28-day period following the study enrollment. One hundred and eighty healthy blood donors were genotyped and used as controls.

**Results** The genotype distribution in the patients’ group was comparable with that observed in controls (P = 0.45). ACE I/D polymorphism and circulating ACE levels were not associated with mortality (P > 0.05) or with secondary outcomes including ventilation-free days and days without cardiovascular or renal failure among septic critically ill patients (P > 0.05). See Figure 1.

**Conclusions** Neither the ACE I/D polymorphism nor the serum ACE levels seem to be significant prognostic factors of the outcome of sepsis in critically ill patients.

**Figure 1 (abstract P282).** Kaplan–Meier curves of survival up to 28 days for the three ACE gene polymorphisms.

Comparison of the effects of recombinant human soluble thrombomodulin for systemic inflammatory response syndrome-associated coagulopathy with and without continuous hemodiafiltration
SM Matsuo, T Ikeda, K Ikeda, H Ikeda, S Suda, M Hiramatsu
Tokyo Medical University, Hachioji Medical Center, Tokyo, Japan

Introduction Recombinant human soluble thrombomodulin (rhs-TM) has a potent anticoagulant effect on septic disseminated intravascular coagulation (DIC) by binding to thrombin and activating protein C. The infusion dosage of rhs-TM should be reduced for patients with renal failure. The aim of this study was to compare the effects of rhs-TM for systemic inflammatory response syndrome (SIRS)-associated coagulopathy (SAC) with and without continuous hemodiafiltration (CHDF).

Methods The subjects were 12 patients with SAC treated with rhs-TM in our ICU. Of these, six received 380 units/kg/day rhs-TM, and six who were undergoing CHDF received 130 units/kg/day for 6 to 7 days. We analyzed the changes in DIC, sequential organ failure assessment (SOFA) and SIRS scores, platelet counts, antithrombin levels, fibrin/fibrinogen degradation products (FDP) and prothrombin time internationalized ratio (PT-INR) after each treatment with rhs-TM. The values are expressed as means ± SD and were analyzed using Student’s paired t test and the Wilcoxon t test (P < 0.05).

Results SOFA, DIC and SIRS scores and the values of PT-INR decreased after the administration of rhs-TM in both groups. Platelet counts increased in the group without CHDF and decreased in the group with CHDF, but these changes were not statistically significant. Antithrombin levels also increased in both groups, but these changes were not statistically significant either. FDP decreased significantly only in the group without CHDF. The changes in platelet counts were influenced by CHDF, because platelet counts were decreased only in the group with CHDF. Several reports have mentioned that rhs-TM has an effect of decreasing FDP for SAC. In this study, we observed decreased FDP only in the group without CHDF. We speculate that these results were influenced by an infusion dose of rhs-TM.

Conclusions rhs-TM has a potent effect in improving septic DIC even with an infusion dose of 130 units/kg/day for patients with CHDF.

Microcirculatory effect of hyperbaric oxygen therapy in septic patients
F Ferré, S Silva, J Ruiz, A Mari, O Mathe, P Sanchez-Verlaen, B Riu-Poulenc, O Fourcade, M Génestal
University Teaching Hospital Purpan, Toulouse, France

Introduction Reduced microvascular perfusion has been implicated in organ dysfunction and multiple organ failure associated with severe sepsis. Near-infrared spectroscopy (NIRS) can provide a non-invasive estimation of local tissue oxygenation (StO₂) related to microvascular circulation. Previous investigators have reported a prognosis value of StO₂ measurements realized during severe sepsis. Hyperbaric oxygen (HBO) is recommended as an associated treatment during soft-tissue infection. Interestingly, a microcirculation improvement has been reportedly identified in septic animals treated by HBO. The aim of this study is to evaluate the microcirculatory effect of HBO therapy in septic patients assessing dynamics changes in StO₂.

Methods A prospective study over 1 year investigating 14 septic shock patients secondary to a soft-tissue infection. A concomitant microcirculation (for example, dynamic changes in StO₂), macrocirculation and metabolic assessment was performed before and after HBO session (for the first three). Thenar eminence StO₂ was measured continuously by NIRS during a vascular occlusion test: a 3-minute transient ischemia infusing an arm cuff 50 mmHg above the systolic arterial pressure (Figure 1). Primary end point: StO₂ reperfusion slope variation induced by HBO.

Results The reperfusion slopes on day 1 were lower in nonsurvivors compared with survivors (P = 0.01). HBO increases cardiac output (P = 0.003) and reduces arterial blood lactate (P = 0.001). HBO improves post-ischemic microcirculatory parameters: hyperemic area (P = 0.01), ΔStO₂ (P = 0.02), maximum StO₂ (P = 0.04) and tends to improve reperfusion slope (P = 0.1). A significant negative correlation between reperfusion slope and blood lactate was observed. No correlation between macrohemodynamic and microcirculatory parameters, including baseline StO₂, was observed.

Conclusions If microvascular dysfunction is the key to the development of multiple organ failure in sepsis, the microcirculation should be a key therapeutic target. Our data confirm a good predictive value for outcome of the StO₂, reperfusion slope at admission. Originally, we demonstrated a post-ischemic NIRS parameter improvement by HBO therapy. This microcirculatory effect, independent of the HBO action on systemic hemodynamic parameters, was associated with a significant reduction of arterial lactate, a major prognostic factor in septic patients. These variations are probably due to capillaries recruitment induced by microvascular reactivity modifications.

Lipid metabolism in critically ill patients: a microdialysis study
M Theodorakopoulou1, N Nikitais2, S Orfanos1, I Maratos1, E Bountaf1, A Diamantakis1, A Armaganidis1, I Dimopoulou1
1Attikon University Hospital, Athens, Greece; 2Alexandra General Hospital, Athens, Greece

Introduction Microdialysis (MD) is a bedside in vivo sampling technique that permits continuous analysis of a patient’s interstitial fluid chemistry without consuming blood. As the interstitial fluid bathes the cells, its composition reflects the local metabolic activities of those cells, thus reflecting intracellular metabolic changes and disorders. In vivo MD is performed by implanting a commercially available catheter that mimics a blood capillary at the site of interest. In this study, we used MD to assess the metabolic changes of lipids in mechanically ventilated patients with sepsis.

Methods Thirty-seven (21 men) mechanically ventilated septic patients were studied. All patients met the ACCP/SCCM consensus criteria for sepsis. Upon sepsis onset, an MD catheter was inserted into the subcutaneous tissue of the upper thigh. The dialysate samples were collected and analyzed immediately for glycerol using a mobile analyzer. Measurements were performed six times/day during the first 6 days from the sepsis onset. The daily mean values of the MD measurements were calculated. Blood samples were taken on the same days and were analyzed for total cholesterol, high-density lipoprotein (HDL), low-density lipoprotein (LDL), triglycerides, glycerol and free fatty acids (FFA).

Results FFA increased significantly during the first days of sepsis with a peak at days 3 and 4 (P < 0.05). Total cholesterol and LDL decreased significantly during the first 3 days of sepsis (P < 0.05). HDL increased significantly during the first 3 days of sepsis (P < 0.05) and then decreased significantly during the last 3 days of sepsis (P < 0.05).
fatty acids (FFA). Results are expressed as mean ± SD. APACHE II and SOFA scores were also calculated.

**Results** Thirty-seven (21 men) critically ill septic patients with a mean (± SD) age of 65 ± 18 years were studied. APACHE and SOFA at study entry were 22 ± 4 and 8 ± 3, respectively. Sepsis was related to SIRS (n = 1), severe sepsis (n = 7) and septic shock (n = 29). Mortality was 43%. Serum cholesterol (81 ± 42 mg/l) along with HDL (16 ± 17 mg/dl) and LDL (63 ± 37 mg/dl) were low. Serum triglycerides (158 ± 91 mg/dl) were elevated and FFAs (0.41 ± 0.27 mmol/l) were within normal limits. Serum glycerol was high (26 ± 20 mmol/l). Interstitial glycerol was also elevated (331 ± 190 μmol/l). Serum FFAs correlated with both serum (r = 0.43, P = 0.009) and interstitial (r = 0.33, P = 0.04) glycerol.

**Conclusions** Critical sepsis is characterized by an increase in serum and tissue glycerol and preserved FFA levels; these indicate enhanced lipolysis and an increased FFA uptake by peripheral tissues. Serum or interstitial glycerol are better indices of lipid mobilization than serum FFA levels in mechanically ventilated septic patients.

Does each element of the sepsis resuscitation bundle equally improve patient outcome?

B Alessia, MT Kreegan, GE Schramm, O Gajic

Mayo Clinic, Rochester, MN, USA

**Introduction** The Institute for Healthcare Improvement advocates the use of bundles to implement the sepsis guidelines. There are limited data addressing which elements improve survival [1]. We analyzed the data from a previous study to determine the independent impact of each element on patient outcome. We hypothesized that not all elements of the bundle have equal impact on outcome.

**Methods** The seven elements of the sepsis resuscitation bundle include lactate measurement, blood culture before antibiotic, timely antibiotic, adequate fluid resuscitation, appropriate vasopressor use, appropriate red blood cell (RBC) transfusion, and appropriate inotrope use. Baseline variables and the elements of the resuscitation bundle associated with mortality by univariate analyses at P <0.1 were included the propensity score. The univariate associations between the baseline variables and mortality were obtained from our previous study. The propensity scores were estimated using multiple logistic regression analysis.

**Results** The study included 962 patients. Lactate measurement, timely blood culture and antibiotic administration, appropriate fluid resuscitation, and appropriate inotrope use were associated with increased mortality at P <0.1 using univariate analyses. Using the propensity score of each bundle element for adjustment, compliance with lactate measurement and inotrope administration were independently associated with decreased risk of death (Table 1). Timely antibiotic administration had a trend toward risk reduction, the P value did not reach statistical significance. Obtaining blood culture before antibiotic administration, vasopressor administration, and RBC transfusion were not associated with decreased risk of death.

**Table 1 (abstract P286)**

<table>
<thead>
<tr>
<th>Bundle element</th>
<th>OR (95% CI)</th>
<th>P value</th>
</tr>
</thead>
<tbody>

</table>

**Conclusions** Using the propensity score to adjust for compliance with each bundle element, lactate measurement and inotrope administration were independently associated with reduced risk of death.

**Reference**

no evidence of malignancy. The mean neutrophil count was 0.2 x 10^9/l and 52% had zero count during their ICU stay. A total of 41.3% had positive blood cultures. Mortality with negative blood cultures was 73%. Overall 30-day mortality was 58.6% and 1-year mortality was 79.3%. Ventilator support was needed in 83% with a mortality of 88%. Inotropes were required in 48.2% and there was a 71% 30-day mortality. Renal support was commenced in 27.5% with 100% mortality. The 30-day mortality was 100% in patients requiring invasive ventilation and renal support. Mortality was also 100% in those requiring three-organ support (Figure 1).

**Conclusions** Our data suggest a significant mortality in mechanically ventilated patients with neutropenic sepsis. This rises to 100% if two or more organs are supported, especially if one of them is the kidney. Early recognition and intervention to prevent progression to multiorgan failure is paramount to improve outcomes.

Belgian dispatchers’ telephone cardiopulmonary resuscitation protocol training: an evaluation study
A Ghuysen1, M El FAssi1, S Stipulante2, V D’orio1

1 CHU Liège – ULG, Liege, Belgium; 2 SPF Public Health Services, Liege, Belgium

**Introduction** Early bystander cardiopulmonary resuscitation (CPR) training is one of the most effective interventions in improving outcome from sudden out-of-hospital cardiac arrest. However, despite large-scale community training programs, citizen-CPR rates have been persistently low. Therefore, a recent report of the 2010 European Resuscitation Council guidelines has re-emphasized the need for dispatchers to be specifically trained in starting telephone CPR protocol for suspected cardiac arrest. In accordance, 112 Belgian dispatchers have been trained for resuscitation assistance by telephone, using a specific protocol named ALERT (Algorithme Liégeois d’Encadrement à la Réanimation Téléphonique). The present work evaluates the educational aspects of this recent implementation.

**Methods** This was a prospective multicentric study including all French-speaking dispatchers in Belgium (n = 140). The aim was to assess the added value of the training, based on the model of Donald Kirkpatrick that allowed gathering information about perceptions of dispatchers, their satisfaction with the training and their actual ability to apply the protocol.

**Results** Dispatchers had a good pre-existing overall knowledge of CPR (80%), which was nevertheless significantly increased by the training (97%). There was a significant improvement in perceptions of dispatchers regarding their assistance skills (+44%). The training provided a significant improvement in staff perceptions on applicability of the approach on the field, and impacts for the victims. Participants (96%) were generally satisfied with the training. Finally, participating knowledge on public health issues (33%), basic life support (+17%) and dispatching protocol (+19%) was significantly improved.

**Conclusions** French-language federal training in the 100/112 dispatching centers significantly improves dispatchers’ perceptions and knowledge of assistance to resuscitation by the ALERT protocol. Such results reinforce the pivotal role of standardized protocols and training in art and science medical dispatching.

Comparison of the Mapleson C circuit, 500 ml and 1.6 l self-inflating bags for delivering guideline-compliant ventilation during simulated adult cardiopulmonary resuscitation
P Sherren, A Lewinsohn, T Jovaisa, S Wijayatilake
Queens Hospital, Romford, UK

**Introduction** Despite all the research and education that has gone into the field of cardiopulmonary resuscitation (CPR), survival rates remain bleak. A significant problem has been the discrepancy between teachings and witnessed clinical practice. As a result of this, and the deleterious outcomes associated with hyperventilation, we conducted a manikin-based study to evaluate three different ventilating devices and their ability to provide guideline-compliant ventilation during simulated adult CPR.

**Methods** A simulated cardiac arrest scenario was undertaken by 33 healthcare professionals (α = 0.05, power = 80%). Participants were asked to ventilate a simulated cardiac arrest patient for a period of 1 minute with all three devices, during which time various ventilatory parameters were recorded using a spirometer. The devices investigated were the Mapleson C circuit, adult (1.6 l) and paediatric (500 ml) self-inflating bags. P <0.01 was deemed statistical significant, due to multiple comparisons.

**Results** The paediatric self-inflating bag performed best, with significant improvement in the mean minute ventilation (P = 0.003), tidal volume (P <0.001) and peak airway pressure (P <0.001). Despite the significant differences, the paediatric self-inflating bag still delivered a mean minute ventilation of 7.01 l/minute, which still exceeds the Resuscitation Council’s suggested 5 l/minute. See Table 1.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>500 ml self-inflating bag</th>

<td>30.3 (11.4)</td>
<td>&lt;0.001*</td>
</tr>
</tbody>
</table>

Data presented as mean (SD). *Statistically significant result. Nonstatistically significant result.

**Conclusions** Participants were found to be hyperventilating simulated cardiac arrest patients with all devices. The paediatric self-inflating bags delivered the most guideline-compliant ventilation and its use in adult CPR may be a simple measure to ensure delivery of more guideline-consistent ventilation.
P291
Comparison of nifekalant and amiodarone for resuscitation after cardiopulmonary arrest due to shock-resistant ventricular fibrillation
University Hospital of Occupational and Environmental Health, Kitakyushu City, Japan

Introduction Nifekalant (NIF) is a pure potassium channel blocker developed in Japan and it has been used widely for treating fatal ventricular tachyarrhythmia since 1999. Because intravenous amiodarone (AMD) was approved in 2007 in Japan, there have been few studies about the comparison of the efficacy of NIF and AMD for resuscitation after cardiopulmonary arrest patients due to shock-resistant ventricular fibrillation.

Methods We performed a retrospective study in 32 consecutive cardiopulmonary arrest patients treated by NIF or AMD due to more than twice shock-resistant ventricular fibrillation from April 2005 to October 2010. The statistical analyses performed by chi-square test and nonpaired t-test.

Results The mean (± SD) age was 62.2 ± 16.1 years and 25 of 32 were male patients. All 32 patients were treated with tracheal intubation and intravenous epinephrine. Seventeen patients received NIF administration and 15 patients received AMD. The average initial administration dose of NIF was 11.1 ± 3.4 mg and that of AMD was 171.7 ± 59.7 mg. The rate of return of spontaneous circulation (ROSC) was 41.2% (7/17) in the NIF administration group and 26.7% (4/15) in the AMD group. There were no significant differences between the two groups with the rate of ROSC and survived discharge in the NIF group. The survived discharge rate from our hospital was 41.2% (7/17) in the NIF administration group and 26.7% (4/15) in the AMD group. The survived discharge rate from our hospital was 41.2% (7/17) in the NIF administration group and 26.7% (4/15) in the AMD group.

Conclusions Although NIF is an anti-arrhythmic agent for life-threatening ventricular tachyarrhythmia, it does not have negative inotropic activity. NIF changes shock-resistant ventricular fibrillation to spontaneous circulation more quickly than AMD. NIF is strongly effective for resuscitation of shock-resistant ventricular fibrillation.

Implementation of the FAST emergency vehicle pre-emption system may improve the outcomes of out-of-hospital cardiac arrests: a 7-year observational study
H Inaba1, Y Tanaka2, K Fukushima3, S Tamasaku3
1Kanazawa University Graduate School of Medicine, Kanazawa, Japan; 2Kanazawa University Hospital, Kanazawa, Japan; 3Kanazawa City Fire Department, Kanazawa, Japan

Introduction The interval of call to arrival is one of the major factors associated with good outcomes of out-of-hospital cardiac arrests (OHCAs). The FAST system helps emergency vehicles reach a scene quickly by controlling the traffic signals. The aim of study is to investigate whether the FAST system may improve the outcomes of OHCAs by decreasing the response time.

Methods We analyzed the data from OHCAs that were witnessed or recognized by citizens from April 2003 to March 2010. The OHCA data were compared between the two groups transported by ambulances with and without FAST units. The comparisons were made in the central and peripheral areas with and without FAST-controlled signals.

Results Dispatch of and transportation by FAST-loaded ambulances significantly decreased the interval of call to arrival and significantly augmented the incidence of sustained ROSC and 1-year survival only in the central area (Figure 1). Monovariate analysis followed by logistic regression analysis revealed that FAST implementation is an independent factor associated with 1-year survival (adjusted odds ratio with 95% CI = 1.306 (1.014 to 1.691)) and sustained ROSC (1.249 (1.108 to 1.410)).

Conclusions The implementation of FAST may improve the outcomes of OHCAs mainly by reducing the interval of call to arrival.

Responsiveness to EMT-performed basic CPR and its duration predict unachievable sustained return of spontaneous circulation and unavoidable hospital death in unwitnessed out-of-hospital cardiac arrests without bystander CPR
H Inaba, Y Takei, M Enami, Y Goto, K Ohta
Kanazawa University Graduate School of Medicine, Kanazawa, Japan

Introduction Various criteria to terminate resuscitation have been reported. EMTs in Japan are not permitted to terminate resuscitation in...
the field. The aim of this study is to test the hypothesis that ECG rhythm response to basic CPR and its duration may predict hospital death.

Methods  The basal data were prospectively collected from 1,437 unwitnessed out-of-hospital cardiac arrests (OHCAs) that were resuscitated by EMTs without the ACLS technique in Ishikawa Prefecture (Figure 1). The cut-off points of basic CPR duration for outcomes were determined. Sensitivity and specificity were calculated.

Results  The improvement of the ECG rhythm by basic CPR predicted the sustained return of spontaneous circulation (SROSC) in hospital. The duration of EMT-performed CPR predicted the outcomes of the OHCAs that were unresponsive to the basic CPR (Figure 2).

Conclusions  Responsiveness to basic CPR and its duration may predict unavoidable death in hospital.

A survey on laypersons’ willingness in performing cardiopulmonary resuscitation

Hiroshima University, Hiroshima, Japan

Introduction Although bystander cardiopulmonary resuscitation (CPR) can improve survival from cardiac arrest, the reported prevalence of bystander CPR remains low in most countries. This study was performed to investigate factors affecting laypersons’ willingness in performing CPR.

Methods Questionnaires including 10 questions regarding personnel backgrounds, knowledge regarding the use of AED, CPR training, willingness in performing CPR, and EMS dispatcher’s advice were distributed to citizens who gathered at a ball park stadium, a typical public place in Hiroshima, Japan.

Results Ten thousand questionnaires were distributed and a total of 5,956 were collected for analysis. Age distributions of the respondents were: <20 years old: 13%, 20 to 49 years old: 67%, 50 to 69 years old: 16%, >70 years old: 3%. Fifty-seven percent were male. Ninety-one percent had heard of AED; however, only 45% knew how to use it. Forty-nine percent took CPR training before. As for the willingness to perform CPR, 38% answered they would start CPR, 34% would do it if any advice was available. On the other hand, 23% said they were not capable of performing CPR, and 4% were not willing to do it. Of those who were not capable of performing CPR, the reasons included lack of knowledge and/or skills to perform CPR (50%), no previous CPR training (27%), concern over harm to the victims (25%), and lack of confidence to determine cardiac arrest (19%). Of those who were willing to perform CPR, 61% answered they would prioritize rescue breathing over chest compression. In comparison of those with and without previous CPR training or knowledge of the use of AED, significant differences were found in the willingness in performing CPR (88% vs. 58%, P < 0.0001; 91% vs. 58%, P < 0.0001, respectively) and doing rescue breathing (55% vs. 29%, P < 0.0001; 64% vs. 57%, P < 0.0001, respectively). Fifty-two percent of the respondents did not know the service of dispatcher-assisted CPR.

Conclusions Our study indicated that proper knowledge of CPR, prior CPR training, and onsite bystander CPR assistance may enhance laypersons’ willingness in performing CPR. More emphasis should be exerted on the roles of chest compression and the EMS dispatcher assistance in CPR education.

Effects and limitations of an automated external defibrillator with audiovisual feedback for cardiopulmonary resuscitation: a randomized manikin study

H Fischer1, J Gruber1, S Neuhold1, S Frantal1, E Hochbrugger1, B Steinlechner1, R Greil2
Medical University of Graz, Austria; 2University Hospital Bern and University of Bern, Switzerland

Introduction Correctly performed basic life support (BLS) and early defibrillation are the most effective measures to treat sudden cardiac arrest. Automated external defibrillators (AEDs) with feedback technology may play an important role in improving CPR quality. The aim of this simulation study was to investigate whether an AED with audiovisual feedback improves CPR parameters during standard BLS performed by trained laypersons.

Methods With ethics committee approval and informed consent, 68 teams (two flight attendants each) performed 12 minutes of standard CPR with the AED’s audiovisual feedback mechanism enabled or disabled. We recorded CPR quality parameters during resuscitation on a manikin in this open, prospective, randomized controlled trial. Between the feedback and control group we measured differences in compression depth and rate as the main outcome parameters and effective compressions, correct hand position, and incomplete decompression as secondary outcome parameters. An effective compression was defined as a compression with correct depth, hand position, and decompression.

Results The feedback group delivered compression rates closest to the recommended guidelines (101 ± 9 vs. 109 ± 15/minute, P = 0.009), more effective compressions (20 ± 18 vs. 5 ± 6%, P < 0.001), more compressions with correct hand position (96 ± 13 vs. 88 ± 16%, P < 0.001), and less leaning (21 ± 31 vs. 27 ± 33%, P < 0.001). However, only the control group adhered to the recommended compression depth (44 ± 7 mm vs. 39 ± 6, P = 0.003).

Conclusions Use of an AED’s audiovisual feedback system improved some CPR quality parameters, thus confirming findings of earlier studies, with the notable exception of decreased compression depth, which is a key parameter that might be linked to reduced cardiac output.

Introduction Cardiopulmonary resuscitation (CPR) guidelines published by the European Resuscitation Council are intended to improve survival of cardiac arrest by implementing medical practice based on scientific findings. This study investigated whether the introduction of the 2005 CPR guidelines, which mandated several fundamental practice changes, improved the rate of return of spontaneous circulation (ROSC) in a physician-staffed prehospital emergency medical system.

Methods Emergency physician protocol sheets from calls responding to cardiac arrest were reviewed and the following data were collected: bystander CPR and bystander use of a semi-automated defibrillator, medication administered by emergency physicians, number of defibrillations, on-the-scene thrombolysis, occurrence of ROSC. These parameters were compared in a 3-year period from each before and after the introduction of the 2005 CPR guidelines.

Results A total of 632 CPR protocols were analyzed, and the groups were comparable regarding age, sex, delay and initial rhythm. Bystander CPR was observed in 35% of the cases, with no difference between before and after the introduction of the 2005 guidelines and was not associated with an increase in ROSC. Bystander use of a defibrillator was rare (2.5%), but was associated with an increase in ROSC. When advanced life support by emergency physicians was considered according to the 2000 guidelines, ROSC occurred in 29% of the cases, whereas ROSC occurred in 36% of the cases after 2005 (P = 0.058). Adrenaline and manual defibrillations were applied less frequently after 2005, whereas amiodarone and atropine were used more frequently. The application of thrombolysis was not different before and after 2005, but was associated with an increase in ROSC.

Conclusions In our setting, the 2005 CPR guidelines apparently failed to reach out to laypersons, as bystander CPR was neither more frequent nor associated with an increase in ROSC. The 2005 guidelines had an impact on advanced life support practice by emergency physicians, but there was only a trend to an increase in ROSC.
found only 4% and the majority of patients had symptoms suggestive of SAH prior to OHCA [2]. Hence, different recommendations regarding routine cranial imaging may be obtained from the two studies.

**Methods** We therefore evaluated retrospectively the rate of SAH in cardiac arrest patients consecutively admitted to our internal medicine ICU. For all patients, CCT and autopsy findings were obtained, if available. In addition we screened emergency room or final medical reports of SAH patients admitted to our neurological ICU for OHCA and resuscitation.

**Results** Cranial computed tomography (CCT) was performed in 129 of 421 (32.6%) cardiac arrest patients admitted to our internal medicine ICU, commonly on the day of admission (52% of CCTs) or within the first week (85%). None of the CCTs showed signs of SAH. Retrospective analysis of all autopsies (n = 18) revealed no postmortem diagnosis of SAH. A retrospective analysis of SAH patients admitted to our neurological ICU revealed only one out-of-hospital resuscitation among 141 SAH patients (0.7%), in line with a recent study [3].

**Conclusions** Our data indicate a low rate of SAH in patients with OHCA, especially when not clinically suspected. For our patient cohort, routine CCT may not be indicated after cardiac arrest. The rate of SAH leading to OHCA seems to differ significantly between Japan and Germany. Our results have to be interpreted with care because of the retrospective study design and possible selection bias. Further prospective studies are needed to confirm the results.

Predicting survival in cardiac arrest patients admitted to intensive care using the Prognosis After Resuscitation score

R Porter, I Goodhart, A Temple
Sheffield Teaching Hospitals NHS Trust, Sheffield, UK

**Introduction** Developed from meta-analysis in 1992, the Prognosis After Resuscitation (PAR) score consists of seven, relatively straightforward to calculate, variables with scores greater than 5 predicting non survival [1]. The aim of this evaluation was to assess PAR scoring as a means of predicting non survival of post cardiac arrest patients admitted to the general intensive care unit (ITU) at Sheffield Teaching Hospitals NHS Trust (STH).

**Methods** Previous local service reviews have collected data on hospital survival and PAR scoring between January 2002 and May 2008 [2,3]. In addition, from May 2008 to July 2010, post cardiac arrest patients were identified from the admissions book and a medical notes review was carried out.

**Results** Since 2002 a total of 225 post cardiac arrest patients have been admitted to the ITU. Forty per cent survived until hospital discharge. The PAR score ranged between –2 and 18, with 0 being the most common score. Four patients from the 37 (13.5%), admitted to the ITU, with a PAR score of greater than 5 survived until hospital discharge. Forty-six per cent of patients with a PAR score of 5 or less survived to hospital discharge. See Figure 1.

**Conclusions** Over the 8 years of review of our data we have only identified four patients where ongoing care was both appropriate and successful despite a PAR score greater than 5. We believe that these patients should have been admitted regardless of the PAR score due to underlying pathology. The PAR score is an invaluable screening tool in justifying the decision not to admit a patient in whom it is felt critical care is not justified. However, caution must be used as the PAR score should be an aid to clinicians rather than the sole factor deciding appropriateness of critical care admission.

Survival after cardiac arrest: what is the situation in Lithuania?

A Macas, G Baksyte, L Plieteris, A Vilkė, A Peckauskas
Lithuanian University of Health Sciences, Kaunas, Lithuania

**Introduction** Treatment of patients after sudden cardiac arrest remains a significant problem. Even after successful resuscitation, most patients have complications – one of the most serious and, unfortunately, very common being postanoxic brain injury. Aims of the study were to estimate the survival time for patients who had sinus rhythm restored after cardiac arrest but had neurological deficiency, and to estimate basic pathology that triggers cardiac arrest.

**Methods** Retrospective data analysis was performed in the coronary care unit of Lithuanian University of Health Sciences Hospital – Kaunas Clinics. Records of 56 patients were analysed (37.5% women and 62.5% men). Age ranged from 46 to 88 years. Average age was 65.32 ± 12.59. Sinus rhythm was restored for all patients after cardiac arrest, but had a neurological deficiency.

**Results** A total 89.28% of patients suffered out-of-hospital cardiac arrest. For 28.6% of patients it was enough to make CPR less than 15 minutes, before revival of sinus rhythm; 33.9% needed 15 to 30 minutes and 37.5% patients had to be resuscitated for more than 30 minutes. Almost one-half of patients (46.4%) did not survive 24 hours after resuscitation. The dominating basic pathology was acute myocardial infarction of the anterior wall (53.6%). The most common neurological deficiency was postanoxic coma (83.9%).

**Conclusions** Almost one-half of patients, which had revival of sinus rhythm after cardiac arrest and had neurological deficiency, did not survive 24 hours after resuscitation. The most common basic pathology, which caused cardiac arrest, was acute myocardial infarction with dominating anterior wall infarction.

Prognosis after cardiac arrest

O’Tourna, G Hadjipavlo

John Radcliffe Hospital, Oxford, UK

Introduction

Unconsciously, mechanically ventilated survivors of cardiac arrest account for a large number of intensive care admissions. Such patients have a spectrum of outcomes, ranging from brain death to good recovery. Predicting the final neurological outcome during the early post-resuscitation phase is required and has been the centre of multiple studies.

Methods

We performed a literature review of studies assessing outcome predictors following cardiac arrest. We also reviewed national and international guidelines on the subject.

Results

In comatose adult patients after cardiac arrest, and who have not been treated with hypothermia and who do not have confounding factors, the absence of the pupillary light response and corneal reflex at day 3 provides the most reliable predictor of poor outcome. The absence of vestibulo-ocular reflexes at ≥24 hours and a GCS motor score of 2 or less at ≥72 hours are less reliable. The presence of myoclonus is not recommended for predicting poor outcome. The presence of myoclonic status epilepticus on day 1 is strongly associated with poor outcome. Several EEG findings are strongly, but not invariably associated with a poor outcome. Malignant EEG findings are associated with false predictive rate of 3%. Bilateral absence of the N2O cortical response to median nerve stimulation during somatosensory evoked potentials (SSEP) predicts poor outcome after 24 hours of cardiac arrest with FPR of 0.7%. There are no high-level studies that support the use of any imaging modality to predict outcome. There is some evidence that loss of distinction between grey and white matter on CT scan predicts poor outcome. Several studies have confirmed a relationship between serum neuron-specific enolase and poor outcome but the cut-off points are not clear. The value of serum S1000 and cerebrospinal fluid creatine kinase brain isoenzyme measurement is not clear. The value of serum S1000 and cerebrospinal fluid creatine kinase brain isoenzyme measurement is not clear. The value of serum S1000 and cerebrospinal fluid creatine kinase brain isoenzyme measurement is not clear.

Conclusions

Reliable predictors of poor outcome after cardiac arrest are the absence of the pupillary and corneal reflexes at day 3. Bilateral absence of the N2O cortical response to median nerve stimulation during SSEP at day 1 is highly accurate. The use of EEG, CT, and neurological biomarkers is not reliable. Limited studies are available for predicting outcome after therapeutic hypothermia.

Incidence of lower respiratory tract infections in patients treated with post-cardiac arrest mild therapeutic hypothermia and selective digestive tract decontamination

NA Vellinga, EC Boerma, MA Kuiper

Medisch Centrum Leeuwarden, the Netherlands

Introduction

Mild therapeutic hypothermia (MTH) is known to have a neuroprotective effect after cardiac arrest (CA). Among the well-recognized side effects is an increased incidence of infections. A useful strategy in preventing lower respiratory tract infections (LRTIs) during MTH is selective digestive tract decontamination (SDD). To this purpose, we examined the use of antibiotics and microbial flora in sputum in post-CA patients treated with MTH and SDD and compared this with the incidence rate during MTH that has been reported in literature.

Methods

We examined sputum (endotracheal aspirate) of all post-CA patients who were treated with MTH (32 to 33°C) during 24 hours after ICU admission and SDD/cefotaxim (SDD/CFT) in our 16-bed mixed ICU in a teaching hospital in the Netherlands in the period January 2007 to December 2008 (n = 55; male = 44, female = 11). Sputum was collected at ICU admission and several days later as part of our SDD/CFT routine. Between 24 and 48 hours after admission, body temperature was actively held below 37°C. LRI was defined as the presence of a potentially pathogenic microorganism (PPM) and the use of antibiotics other than SDD/CFT. The presence of Candida albicans/Candida spp. was considered colonisation and was treated with aerosol antifungal medication.

Results

The in-hospital mortality in our cohort was 30.9%. As can be concluded from our results, in 59.5% of cases a PPM was present in the first sputum during SDD/CFT treatment after admission, with C. albicans being the most prevalent (23.6%). As compared with the sputum on admission, the cultures of the first sputum with SDD/CFT more often showed a monomicrobial isolate (35.5% vs. 40.0%). In sputum of 9/37 (24%) of our patients, a PPM (other than C. albicans/C. spp.) that justifies the use of antibiotics was present, with S. aureus being the most prevalent PPM (13.5%); 5/9 patients were treated with antibiotics, 1/9 received no additional antibiotics, 3/9 were lost to follow-up. Our results point towards a lower incidence of LRI in SDD/CFT-treated patients as compared with non-SDD/CFT-treated patients (88%) who were treated with MTH post-CA [1]. The incidence of LRI in our small cohort (24%) was also considerably lower as compared with a recent study by Nielsen and colleagues (48%) [2].

Conclusions

Our results might point towards a beneficial role of SDD/CFT in preventing LRI during treatment with MTH.

Earlier intra-arrest transnasal cooling may be beneficial

Introduction

Animal studies suggest a life-saving benefit for intra-arrest cooling. Transnasal evaporative cooling has sufficient heat transfer capacity for effective intra-arrest cooling and improves survival in swine. A 200-patient study showed transnasal cooling to be a safe and feasible method of intra-arrest cooling. The study also showed a solid trend to improved neurologically intact survival rates in those patients receiving intra-arrest transnasal cooling.

Methods

To determine effects on neurologically intact survival at 90 days from the addition of intra-arrest transnasal cooling compared with hospital-based cooling alone, patients in witnessed cardiac arrest of any rhythm and with CPR ≤15 minutes after a 112 call were randomized to intra-arrest transnasal cooling versus standard ACLS care in two European EMS systems. Transnasal cooling (RhinoChill (RC); BeneChill Inc., San Diego, CA, USA) was initiated using a mixture of volatile coolant plus oxygen for rapid evaporative heat transfer. In treatment patients, cooling was initiated pre-ROSC, during ongoing CPR. Patients in both groups were cooled upon hospital arrival.

Results

Forty-one patients have been included thus far. The median time from the 112 call for EMS to start CPR was 7 minutes and the time to initiate cooling was 17 minutes. ROSC was achieved in 8/19 (42%) of the RC group versus 8/22 (36%) of the control group. Site 1 initiated cooling at 11 minutes, and the ROSC rate at this site was 3/6 (50%) for RC versus 7 minutes in controls. Site 2 initiated cooling at 11 minutes, and the ROSC rate at this site was 5/13 (39%) for RC compared with...
7/13 (54%) in the controls. EMS was initiated at 7 minutes in RC versus 9 minutes in controls. Conclusions Initiating transnasal cooling extremely early during arrest may be superior to later intra-arrest initiation in relation to ROSC rates. The impact of this ultra-early cooling on outcome remains to be determined.

Hyperoxia post cardiac arrest: experience of a UK ICU
L. Tameem, K. Rooney, S. Deep, M. Thomas
Bristol Royal Infirmary, Bristol, UK

Introduction A recent US multicentre study demonstrated an increased mortality in intensive care patients exposed to high arterial oxygen levels following return of spontaneous circulation (ROSC) after cardiac arrest [1]. We attempted to ascertain the incidence of hyperoxia and associated mortality in a similar cohort of patients in the UK.

Methods We performed a retrospective observational study of a computerised database (Draeger Innovian) over a 14-month period (March 2009 to May 2010). All adult, nontraumatic cardiac arrests within 24 hours of admission to the ITU were included. Sixty-nine patients were identified.

The following data points were analysed: FiO2, pO2 and outcome. Time to first ABG and the PaO2/FiO2 (P/F) ratio were calculated. As per the US study, hyperoxia was defined as a pO2 <60 mmHg or P/F ratio <300; hyperoxia as PaO2 >300 mmHg. Normoxia was the values in between.

Results Ninety per cent of patients had an arterial blood sample within the first hour after admission, compared with the US study where 27.5% of patients did not receive an arterial sample within the first 24 hours. Hyperoxia was only half as common in our population and was associated with the lowest mortality rate (50%). This is at odds with the Kilgannon study, which showed that hyperoxia was associated with the highest mortality [1]. Using their definition of hyperoxia, there is no significant difference in mortality between hyperoxia and normoxia in our study. If hypoxia is defined as pO2 <60 mmHg then the hypoxia rate is only 2.9% with a mortality rate of 100%.

Conclusions In a single UK adult ICU attached to a cardiac arrest centre, hyperoxia after cardiac arrest was uncommon and associated with the lowest mortality. This is associated with increased vigilance in measuring arterial blood gases. Recent guidelines from the Resuscitation Council advise that inspired oxygen should be titrated to achieve a SaO2 of 94 to 98% due to potential harm from hyperoxia [2]. This assertion is not borne out by our data. The definition of hyperoxia is important as there is a significant difference in both incidence of hypoxia and mortality rates dependent on whether the P/F ratio is considered. In practical terms, clinicians can only aim to optimise their arterial oxygen saturations, not the P/F ratios.

Ammonia and lactate blood levels on hospital arrival predict neurological outcome in patients with out-of-hospital cardiac arrest
K. Shinokazi1, S. Oda1, T. Sadahiro1, M. Nakamura2, Y. Hirayama3, E. Watanabe4, Y. Tateishi2, K. Nakanishi3, N. Kitamura4, H. Hirasawa2
1Chiba Aoba Municipal Hospital, Chiba City, Japan; 2Graduate School of Medicine, Chiba University, Chiba City, Japan; 3Narita Red Cross Hospital, Narita City, Japan; 4Kimitsu Chuo Hospital, Kisarazu City, Japan

Introduction There is no reliable predictor on arrival at hospital for neurological outcome of the patient with out-of-hospital cardiac arrest (OHCA). We hypothesize that ammonia and lactate may predict neurological outcome.

Methods We performed a prospective observational study. Nontraumatic OHCA patients who gained sustained return of spontaneous circulation and were admitted to an acute care unit were included. Blood ammonia and lactate levels were measured on arrival at hospital. The patients were classified into two groups: favorable outcome group (Cerebral Performance Category (CPC) 1 to 2 at 6-month follow-up), and poor outcome group (CPC 3 to 5). Basal characteristics obtained from the Utstein template and biomarker levels were compared between these two outcome groups. Independent predictors were selected from all candidates using logistic regression analysis.

Results Ninety-eight patients were included. Ammonia and lactate levels in the favorable outcome group (n = 10) were significantly lower than those in the poor outcome group (n = 88) (P <0.05, respectively). On receiver operating characteristic analysis, the optimal cut-off value for predicting favorable outcome was determined as 170 μg/dl ammonia, 12.0 mmol/l lactate (area under the curve: 0.714 and 0.735, respectively). Logistic regression analysis identified ammonia (≥170 μg/dl), therapeutic hypothermia and witnessed by emergency medical service personnel as independent predictors of favorable outcome. When both these biomarker levels were over threshold, the positive predictive value (PPV) for poor outcome was calculated as 100%.

Conclusions Ammonia and lactate blood levels on arrival are independent neurological prognostic factors for OHCA. The PPV with the combination of these biomarkers predicting poor outcome is high enough to be useful in clinical settings.

Use of the Medicool™ cooling system to increase efficacy of therapeutic hypothermia post cardiac arrest
I. Goodhart, R. Porter, A. Temple
Sheffield Teaching Hospitals NHS Trust, Sheffield, UK

Introduction Patients admitted to intensive care (ITU) at Sheffield Teaching Hospitals who have had a cardiac arrest are cooled according to the local therapeutic hypothermia (TH) protocol regardless of rhythm or location of arrest [1]. A previous audit identified poor efficacy in cooling patients to target [2]. Following this, the Medicool™ device was purchased to improve cooling. This aim of this evaluation is to assess the efficacy of cooling with Medicool™.

Methods Following local audit committee approval, patients admitted between May 2008 and July 2010 were retrospectively identified from ITU admission records. The following data were collected: demographics, arrest and admission characteristics, details of TH and outcome. Previous audit data from 2008 were also examined [2].

Results Sixty-five patients were admitted to the ITU following cardiac arrest between May 2008 and July 2010. The median age was 67 years (29 to 81), 66% were male. Fifty-two per cent survived to hospital discharge. Forty-eight patients were eligible for cooling; in 43 cooling was performed: 26 were cooled using Medicool™ and 17 using traditional techniques. The median time to reach the target temperature was 4 hours with Medicool™ and 5 hours with traditional techniques. In six patients, cooling was abandoned. In patients who completed 24 hours of cooling, 57% of the Medicool™ patients and 31% of the traditionally cooled patients remained in the target temperature for the entire 24 hours. No patients (n = 20) in the previous audit were...
maintained within the target temperature for 24 hours using traditional techniques. See Figure 1.

**Conclusions** The Medicool™ system increases both the cooling rate and the efficacy of cooling in patients undergoing TH. We would advocate the use of Medicool™ over the traditional cooling techniques. It is more effective and additionally when compared with other more invasive cooling techniques is cheaper to instigate, easy for healthcare professionals to use and is associated with less side effects.

Choline kinetics in patients undergoing hypothermia treatment: a case observation in six cardiac arrest patients

T Schröder
Charité-Universitätsmedizin Berlin, Germany

**Introduction** Lately it has been proven that mild therapeutic hypothermia (MTH) after cardiac arrest (CA) weakens the prognostic value of both neurological tests and serum markers, established before MTH was implemented [1-3]. Current prognostication and decision criteria have to be re-evaluated as well as new markers being necessary. Whole blood choline (WBCHO) and plasma choline (PLCHO) are promising new markers in cardiac arrest patients and they are under investigation as markers for global tissue ischemia [4-6]. It is unknown whether the recommended MTH treatment in patients after CA will influence choline levels. Therefore we analyzed choline kinetics in CA patients undergoing hypothermia treatment as a feasibility trial.

**Methods** All patients received MTH irrespective of the initial rhythm. Blood samples were taken on admission then again when reaching the therapeutic temperature of 33°C and after 12 hours of MTH at 33°C. All samples were stored at –80°C [4]. In order to determine the whole blood and plasma choline levels; high-pressure liquid chromatography combined with a mass spectrometer technique was used.

**Results** Six patients after cardiac arrest were analyzed in this feasibility trial. Four patients were male, two female. Median age was 66.5 years (interquartile range 57.5 to 82.25). Choline analyses revealed in five patients increased choline levels (>10 μmol/L) on admission. Four patients showed a peak in both PLCHO and WBCHO when the 33°C target temperature during cooling was reached. Although MTH was maintained over 24 hours, in all cases the patients’ choline levels decreased already after 12 hours of treatment to low or even subnormal concentrations.

**Conclusions** Both whole blood choline and plasma choline demonstrated a release pattern in patients after cardiac arrest undergoing hypothermia treatment. Larger studies have to evaluate the kinetics in detail and the potential prognostic implications of low or high choline levels in cardiac arrest patients.

Employing knowledge translation interventions to increase the use of therapeutic hypothermia post arrest: the SPARC Network Trial

LJ Morrison, P Dorian, KN Dainty, S Brooks, K Thorpe, C Zhao, D Scales
University of Toronto, Canada

**Introduction** Current guidelines recommend early institution of therapeutic hypothermia (TH) in survivors of out-of-hospital cardiac arrest (OHCA). However, recent surveys show that TH is delivered inconsistently, incompletely, and with undue delay. Targeted knowledge translation (KT) strategies may increase the proportion of OHCA patients receiving TH.

**Methods** We conducted a stepped-wedge cluster randomized trial to evaluate the effectiveness of a multi-faceted KT strategy for increasing TH use in a network of 37 hospitals. After a baseline period of 1 year, four wedges of six hospitals were randomized to receive 1 year of passive KT followed by 4 months of active KT. PASSIVE KT included a generic protocol and order set; active KT included network events, performance feedback and ongoing nurse educator support. The primary outcome was the rate of successful TH, defined as a temperature of 32 to 34°C within 6 hours of emergency department (ED) arrival.

**Results** During the study the 4,742 OHCA patients were transported to hospital and 1,063 (22%) were eligible for TH. Overall, both KT interventions were effective at increasing the rate of successful TH (Figure 1), and passive KT led to marked improvements over baseline (96/395 vs. 30/320 patients; OR = 2.24, 95% CI = 1.54 to 3.26; P < 0.05). Active KT did not improve the primary outcome compared with passive KT (86 of 348 patients with active KT; OR = 0.94, 95% CI = 0.70 to 1.28; P = 0.70); however, it did significantly increase rates of initiating TH in the ED (P = 0.04). Inappropriate TH remained rare (5 to 6% of patients) during both KT phases.

**Conclusions** A multifaceted KT intervention markedly improved rates of TH in a large network of hospitals. Simple passive KT strategies were highly effective in increasing TH rates, whereas more active KT improved the use of TH in the ED.

Microvascular dysfunction in patients after successful resuscitation

P Biever, T Schwab, P Roos, O Willnauer, U Denz, K Fink, C Bode, HJ Busch
University Hospital Freiburg, Germany

**Introduction** The crucial role of the microcirculation for improved neurological outcome in patients after successful resuscitation has been discussed for many years. Near-infrared spectroscopy has been proposed as a non-invasive tool to measure continuously the haemoglobin saturation in the terminal vascularisation within the tissues (STO₂) of thaner emanence and to detect microvascular dysfunction by performing a vascular occlusion test (VOT). This study’s purpose was to explore the alteration in microcirculation in patients after successful resuscitation.
Methods Since August 2010 to date, 23 successfully resuscitated patients were prospectively enrolled in an observational study in the medical intensive care department of Albert Ludwigs University, Freiburg. VOT and the time to recanalisation were measured at admission to hospital (t1), after induction of mild therapeutic hypothermia (t2) and after re-warming (t3). The VOT was performed by stopping arterial infl ow by infl ating the arm cuff definitely above the systolic arterial pressure over 3 minutes and recorded with the InSpectra StO2 650 monitor (Hutchinson). The recorded StO2 alterations were analysed utilising the InSpectra StO2 Researcher’s Software V 4.01.

Results Patients after successful resuscitation showed a baseline StO2 of 78.7 ± 8.3%. In all three time points a reduced occlusion slope (t1: −7.2 ± 1.8; t2: −5.8 ± 1.2; t3: 7.6 ± 2.7%/minute) as well as a reduced recovery slope (t1: 1.7 ± 1.1; t2: 1.2 ± 0.7; t3: 1.9 ± 1.7%/second) was seen. Time to recanalisation was on average 2.7 ± 3.6 seconds.

Conclusions Here we could demonstrate important alterations of the tissue-dependent microvascular capacity in patients after successful resuscitation. Considering these data, patients in the post-resuscitation phase may have severe microvascular dysfunction compared with healthy people as described in the literature. This study may highlight a new potentially critical clinical paradigm: extending the duration of mild therapeutic hypothermia may result in favourable neurological outcome by improving post-resuscitation microcirculation.

Application of high-frequency jet ventilation for patients with severe traumatic brain injury
DM Sabirov, RN Akalaev, MB Krasnenkova, AL Rosstalnaya
Tashkent Institute of Postgraduate Medical Education, Tashkent, Uzbekistan

Introduction We carried out research of a brain blood-groove with the purpose of estimating cerebrovascular effects with high-frequency artificial ventilation of lungs in 30 patients with severe traumatic brain injury.

Methods Traditional intensive therapy in conditions of various modes of respiratory support was performed: CMV – 10 patients, SIMV – 10 patients, HFJV – 10 patients. Adequacy of modes of ventilation was estimated on SpaO2, 96 to 99%, and pCO2, 34.7 to 35.2 mmHg. The median age was 36 ± 6 years, GCS was 7 to 9 points; the level of ICP exceeded 15 mmHg. We registered the cerebral blood flow velocity (Vm), resistance pial vessels (Pi), and dilatation reserve (Ri).

Results The analysis of parameters of central and system hemodynamics with varying respiratory support revealed significant distinctions. At mode CMV: ICP – 38 ± 6.7 mmHg; Vm – 51.1 ± 1.4 cm/second; Pi – 1.84 ± 0.1; Ri – 1.28 ± 0.01; CPP – 67.4 ± 1.2 mmHg. At SIMV: ICP – 31.7 ± 1.7 mmHg; Vm – 52.6 ± 4.1 cm/second; Pi – 1.60± 0.1; Ri – 1.23 ± 0.2; CPP – 68.0 ± 2.8 mmHg. At HFJV: ICP – 18.8 ± 2.9 mmHg; Vm – 57.8 ± 7.1 cm/second; Pi – 1.39 ± 0.2; Ri – 1.36 ± 0.01; CPP – 64.1 ± 6.1 mmHg. At CMV adverse conditions for venous return that can be accompanied by depression of intimate emission are created. Decrease in intimate emission will lead to decreased CPP that leads to spasm of pial vessels, and the dilatation reserve will not react to increased tone of pial vessels. At variance, SIMV is markedly similar to CMV interference of autoregulation parameters of the brain blood-groove and system hemodynamics. At HFJV there are no negative phenomena inherent in traditional ventilation. Presence of the kept or increased intimate emission appears to provide more chance to keep cerebral perfusion. At HFJV an authentically lower level of resistance Pi, higher parameter of Ri and lower ICP is marked. This interferes with occurrence of the expressed spasm and ischemia of the brain. At both variants of traditional ALV, the expressed infringements of perfusion and resistance of vessels of the pial–capillary system accompanied by substantial growth are marked.

Conclusions HFJV as respiratory support in severe traumatic brain injury, on a background of intracranial hypertension, has doubtless advantages before traditional methods of ALV. Its application provides preservation of active autoregulation of brain blood circulation, and promotes stabilization of intracranial pressure at a lower level.

P311

Efficacy and safety of dopamine agonists in traumatic brain injury: a systematic review of randomized controlled trials
AL Frenette1, S Kanji1, L Rees1, DR Williamson1, MM Perreault1, AF Turgeon1, F Bernard1, DA Fergusson1
1Hôpital du Sacré-Coeur de Montréal, Canada; 2Ottawa Hospital, Ottawa, Canada; 3Montreal General Hospital, Montreal, Canada; 4Hôpital Enfant-Jésus de Québec, Canada; 5Ontario Health Research Institute, Ottawa, Canada

Introduction In the ICU, dopamine agonists (DA) have been used in TBI patients to augment or accelerate cognitive recovery and rehabilitation. However, the efficacy and safety of DA in this population is not well established.

Methods We conducted a systematic review of randomized controlled trials (RCT) examining the clinical efficacy and safety of DA in TBI. We searched MEDLINE, Embase and the Cochrane Central Register of Controlled studies up to June 2010. We sought trials comparing the effect of a DA with either placebo, standard treatment or another active comparator. We included trials addressing efficacy using any outcome measure as a primary outcome and/or safety. There was no restriction for age, date, or language of publication. We excluded unpublished and animal trials. Sensitivity analyses were planned to evaluate the potential effect of timing of TBI, age, drugs and year of publication on efficacy.

Results Among the 790 citations identified, 20 RCTs evaluating methylphenidate, amantadine and bromocriptine were eligible. Significant heterogeneity pertaining to timing from injury to randomization, mechanism of trauma, severity of TBI and age was observed between and within trials and precluded from any pooling of data. Efficacy outcomes included mainly neuropsychological measures of cognitive functioning. A total of 76 different neuropsychological tests were used, but most of them (59%) only once. For the 12 tests used in more than one study, statistically positive results were reproduced three times. Only five studies systematically assessed safety using predefined objective measures or tools. No trend could be drawn from the analysis of efficacy and safety in any of the predefined categories of outcome. Important sources of bias in the studies were of major concern, including inappropriate use of cross-over design and under-reporting of randomized methods.

Conclusions We observed a variability of neuropsychological tests. This may reflect disagreement regarding clinical relevance of cognitive and behavioral outcomes and lack of a gold standard test for each domain. Considering the absence of consensus along with the high risk of bias in included trials, more research is warranted before DA can be recommended to improve cognitive recovery in critically ill TBI patients.

Update on the RESCUEicp decompressive craniectomy trial
PJ Hutchinson1, AG Kollias1, IT Timofeev2, E Corte11, M Czosnyka1, DK Menon1, JD Pickard1, PJ Kirkpatrick1
1Academic Division of Neurosurgery, Addenbrooke’s Hospital & University of Cambridge, UK; 2Neurocritical Care Unit & University Department of Anaesthesia, Addenbrooke’s Hospital & University of Cambridge, UK

Introduction The fundamental pathophysiological process following head injury is the development and propagation of an escalating cycle of brain swelling, increase in intracranial pressure (ICP), reduction in blood supply and oxygen delivery, energy failure and further swelling, enhancing brain injury and poor outcome. The aim of the RESCUEicp trial (Randomised Evaluation of Surgery with Craniectomy for Uncontrollable Elevation of ICP) is to provide class I evidence as to whether decompressive craniectomy is effective for the management of patients with raised and refractory ICP following traumatic brain injury (TBI).

Methods An international multicentre randomised trial comparing decompressive craniectomy with optical medical management
(including barbiturate therapy). Inclusion criteria: TBI, age 10 to 65, ICP (>25 mmHg for 1 to 12 hours, refractory to first-line treatment). Exclusion criteria: treatment with barbiturates pre-randomisation, primary decompression (during evacuation of mass lesion), bilateral fixed and dilated pupils, bleeding diathesis, devastating injury unlikely to survive >24 hours. In this study, patients are managed on ICUs using a standard protocol. The major objective of this protocol is to maintain ICP <25 mmHg by applying treatment measures in a number of stages. The total number of patients will be 400 (200 in each arm of the study) for a 15% difference in outcome (power = 80%, P = 0.05). The primary outcome measure was extended Glasgow Outcome Score at 6 months.

Results Over 280 patients have been recruited to date from more than 40 centres in 17 countries. The follow-up rate at 6 months is 96%. To date, evaluation of the first 182 patients shows equal distribution of characteristics between the two arms. Median age is 33 years and 80% of patients are male. Four percent were hypoxic and 13% hypotensive at initial presentation. Seventy percent had an initial GCS of 3 to 8, 19% a GCS of 9 to 12 and 11% a GCS of 13 to 15.

Conclusions Randomising patients with TBI to decompressive craniectomy versus optimal medical management is feasible. Whether this operation is effective remains to be seen. We welcome the participation of more centres.

Cerebral oxygen monitoring in intensive care
G Hadjipavlou1, O Touma2
1Nuffield Department of Anaesthetics, Oxford, UK; 2Oxford Radcliffe Hospitals, Oxford, UK

Introduction The purpose of this literature review is to look at the potential of cerebral oxygen monitoring in the intensive care setting and how this monitoring modality will impact our current practice.

Methods A PubMed literature search was conducted using the search terms cerebral oxygenation, and monitoring. The search was limited to adults and the search limited to the title or abstract. Articles selected were those that demonstrated a positive or negative benefit of cerebral oxygen monitoring on neurological outcome after surgery or intensive care.

Results The search revealed a total of 449 possible articles when conducted in December 2010. This was narrowed down to 18 articles related to monitoring cerebral oxygen. Patient outcomes: cerebral oxygen monitoring and the aggressive treatment of cerebral hypoxia reduced mortality and improved long-term outcomes after traumatic brain injury and coronary artery bypass surgery. Near-infrared spectroscopic cerebral oxygen monitoring is capable of detecting ischaemic cerebral perfusion deficits and may be more sensitive than transcranial Doppler in assessing blood flow and detecting delayed ischaemic deficits in subarachnoid haemorrhage. Cerebral hypoxia can persist despite good cerebral perfusion and normal intracranial pressure. Cerebral oxygenation monitoring can prevent iatrogenically driven hyperoxia and hyperperfusion, and can detect cerebral hypoxia before signs of standard pulse oximetry monitoring.

Conclusions The authors believe evidence is gathering supporting that cerebral oxygen monitoring may play an important role in neurointensive and adult intensive care centres. Cerebral hypoxia worsens long-term neurological outcomes, and this modality has potential to help reduce morbidity.

Optimising follow up and outcome assessments in traumatic brain injury trials
LJ Murray1, JD Cooper1, JV Rosenfeld1, Y Arabi2, A Davies3, P D’Urso1, T Kossmann1, J Ponsford3, P Reilly1, I Seppelt1, R Wolfe4, S Vallance5, B Howe6, M Alikshi2

Introduction Traumatic brain injury studies predominately use an assessment of neurological function some time after hospital discharge as the primary endpoint. Recent studies have followed up patients at 6 months after injury with very variable loss to follow up [1,2]. We have established an outcome process that minimises loss to follow up and maximises the quality of the outcome assessment.

Methods The DECRA trial is a prospective randomised trial of 155 patients from Australia, New Zealand, and Saudi Arabia. Patients with severe traumatic brain injury and refractory intracranial hypertension were randomly assigned to receive either a decompressive craniectomy or to continue with standard medical management. The primary outcome was patient’s neurological function using the Extended Glasgow Outcomes Scale (GOSE) at 6 months after injury. Patients were tracked following hospital discharge by the Research Coordinators at each participating site. The GOSE assessments were conducted by three blinded assessors using structured telephone questionnaires. The assessment team was led by an experienced assessor. Two assessors were located in Australia and one assessor in Saudi Arabia. Assessors were trained using a prepared training package of examples and self-testing exercises. The chief assessor reviewed the outcome assessments performed by the other assessors. Any complex assessments were referred to an assessment panel for a consensus decision.

Results DECRA commenced recruitment in 2003 and the last patient was enrolled in April 2010. Research coordinators successfully tracked all surviving patients, which resulted in a 100% follow-up rate for the primary study outcome measure.

Conclusions We have successfully completed a prospective randomised controlled trial with zero loss to follow up for the primary outcome measure of GOSE at 6 months. Assessments were reviewed by the chief assessor and a consensus panel if required to ensure consistency of the assessment.

Optimising the consent process in severe traumatic brain injury trials
LJ Murray1, D Cooper1, JV Rosenfeld1, Y Arabi2, A Davies3, P D’Urso1, T Kossmann1, J Ponsford3, P Reilly1, I Seppelt1, R Wolfe4
1The Alfred Hospital, Melbourne, Australia; 2King Fahad National Guard Hospital, Riyadh, Saudi Arabia; 3Epworth Healthcare, Melbourne, Australia; 4Monash University, Melbourne, Australia; 5Adelaide University, Adelaide, Australia; 6Nepean Hospital, Sydney, Australia

Introduction Severe traumatic brain injury (TBI) is a condition often associated with grave consequences and it remains a major public health problem globally. Clinical trials to improve management and treatment of this condition are a necessity; however, there are many issues that impact on the design and conduct of such trials including the complex and sensitive issue of consent. Obtaining consent for severe TBI trials is inherently complicated and difficult because the
family are being asked to make an informed decision when they are shocked, anxious, grieving and frequently physically exhausted. We established a process during the DECRA trial to minimise the difficulties and to ensure that consent was obtained with sensitivity and in an informed manner.

**Methods** The DECRA trial is a prospective randomised trial of 155 patients from Australia, New Zealand, and Saudi Arabia. Patients with severe traumatic brain injury and refractory intracranial hypertension were randomly assigned to receive either a decompressive craniectomy or to continue with standard medical management. Surrogate consent was obtained prior to randomisation and all participating hospitals had obtained approval from their Human Research & Ethics Committee.

**Results** Guidelines for obtaining consent were included in the protocol and manual of operations, and were discussed at the investigators’ meetings. The guidelines highlighted the importance of early communication with the patient’s medical team regarding possible recruitment into the trial, updating the family about the patient’s condition prior to the consent discussion, following a basic script to ensure all aspects of the trial were covered in the discussion, allowing time for the discussion including follow-up discussions and listening carefully to the family’s questions. DECRA commenced recruitment in 2003 and the last patient was enrolled in April 2010; 168 consent discussions were held with a 92% consent rate.

**Conclusions** Consent rates in brain injury studies in the critical care setting can be optimised by following a protocolised consent process.

**Acknowledgements** The authors thank the DECRA Trial Investigators, the ANZICS Clinical Trials Group, and the Neurosurgical Society of Australia. Funding was received from NHMRC, TAC, VNI, VTF, Intensive Care Foundation and WA Institute for Medical Research.

**Early clinical indices predicting functional survival in severely head-injured patients**  
M Zouka, G Tsaousi, E Anastasiou, E Geka, E Euthymiou, I Soultati, M Giannakou  
AHEPA University Hospital, Thessaloniki, Greece  

**Introduction** Given the burden of disability arising from severe traumatic brain injury (TBI) [1], plain assessment of mortality certainly underestimates the impact of TBI. Therefore, risk prediction models need to provide poor neurological outcome estimates other than mortality. The aim of the study was to determine whether a simple combination of early clinical indices may be predictive of disability after ICU discharge.

**Methods** A prospective study enrolling 133 patients (109 male/76 female) with TBI (associated or not with multiple trauma) and GCS ≤8 admitted to our ICU. Demographics, acute care preadmission factors (hypotension and hypoxemia), injury severity (GCS, ISS, RTS, pupil reactivity, CT scan grade) and acute physiological disturbance (APACHE II – 24 hours, SOFA) were evaluated. According to functional outcome (GOS) upon ICU discharge, two subgroups of patients were identified: GOS 4 to 5 (favorable outcome), and GOS 1 to 3 (poor outcome).

**Results** Data are presented in Table 1. Overall mortality was 32.3% (n = 43). Logistic regression analysis identified APACHE II (P = 0.004), CT scan grade (P = 0.002) and pupil reactivity upon ICU admission (P < 0.01) as the strongest predictors of functional outcome. Area under the ROC curve for APACHE II score was 0.841 (95% CI: 0.767 to 0.899, P < 0.0001).

**Conclusions** Acute physiological disturbance, poor preadmission clinical data and neurological signs, presence of severe intracerebral injuries combined with additional extracerebral injuries and advanced age, seem to be powerful determinants that adversely influence the early course of recovery and functional survival of patients with sustained severe TBI. Among them APACHE II, CT scan grade and pupil reactivity upon ICU admission were identified as the strongest early prognostic indicators.

Stroke and thrombolysis: an old disease with a new approach
N Catorze, I Pessoa, M Abu Hazima, F Camilho
Centro Hospitalar Média Tejo, Abrantes, Portugal

Introduction The incidence of stroke doubles for every decade after 45 years of age, and 70% of these events occur in the over 65s. A rational approach with a thrombolytic protocol can diminish this clinical and social burden.

Methods In the past 20 months all patients with acute stroke were referred to ICU staff for evaluation and compliance to effective thrombolysis until 4.30 hours from the onset of symptoms. All clinicians were advised and trained in the ED was adapted using NIHSS.

Results In this period 152 patients were evaluated and 32 (24.2%) were eligible for reperfusion treatment. Men were more prevalent than women (70.6 vs. 29.4%) and age was distributed between 29 and 82 years. Risk factors were equally distributed (Table 1). Twenty-nine patients (88%) received thrombolysis within 3 hours of symptoms onset and 19 (63%) got better NIHSS after treatment. Eleven patients (37%) never recovered. Five out of 34 patients (12%) were treated in the 3 to 4.30 hours window and three received benefit. All deaths were related to ischemia progression. Table 2 presents complications during the ICU stay.

Conclusions The clinicians’ compliance and patients’ reference to dedicated teams (stroke teams) resulted in the treatment of 22.4% of observed patients (1 to 11% in the literature). Some complications could be avoided with simple measures. This protocol should continue and should be emphasized.

Significance of admission temperature and impact on mortality in critically ill neurological patients
F Rincon1, C Schorr1, C Hunter1, B Milcareck2, R Dellinger1, J Parrillo2, S Zanotti2
1Thomas Jefferson University, Philadelphia, PA, USA; 2Cooper University Hospital, Camden, NJ, USA

Introduction The purpose of this study is to test the hypothesis that hyperthermia is associated with increased mortality after neurological injury using a robust multicenter ICU database.

Methods A multicenter cohort study using the Project IMPACT critical care database of ICUs at 120 US hospitals between 2003 and 2008. Patient inclusion criteria were age older than 17 years, acute neurological injury within 24 hours of admission (acute ischemic stroke (AIS), subarachnoid hemorrhage (SAH), intracerebral hemorrhage (ICH), subdural hematoma (SDH), and traumatic brain injury (TBI)), and admission to the ICU. Patients were divided into three main groups based on definitions of hyperthermia and hypothermia in the ICU. Hyperthermia was defined as temperature greater than 37.5°C, hypothermia as a temperature lower than 36.5°C, and normothermia, not classified as hyperthermia or hypothermia. The outcome measure was in-hospital mortality.

Results Over the 8-year period, the Project IMPACT database contained data on more than 700,000 ICU admissions. We found 16,889 patients that met the inclusion criteria. The mean age was 61 ± 19 years, 9,339 (56%) were male, and 12,634 (76%) were white. Of these, 3,081 (18%) had AIS, 2,413 (14%) had SAH, 4,315 (26%) had ICH, 2,748 (16%) had SDH, and 4,317 (26%) had TBI. The mean admission temperature was 37.5 ± 3°C and the overall mortality was 3,628/16,676 (22%). Of the total cohort, 7,878 (47%) had hyperthermia, 689 (4%) had hypothermia, and 8,167 (49%) were normothermic. The hyperthermia group had a high in-hospital mortality (2,180/7,822 (28%) compared with normothermia (1,169/8,167 (14%)) but the hypothermia group had significantly higher in-hospital mortality (279/687 (41%)). In a preliminary multivariate model controlling for potential confounders (age and gender), hyperthermia (OR, 1.2; 95% CI, 1.1 to 1.23) and hypothermia (OR, 1.9; 95% CI, 1.7 to 2.1) increased the odds of hospital mortality.

Conclusions Among critically ill neurological patients admitted to the ICU, hyperthermia and hypothermia are associated with increased mortality.

P319
Cerebral vasoreactivity is not impaired in patients with severe sepsis
S Szatmári, Z Fülep, P Sárkány, C Antek, P Siro, C Molnár, B Fülesdi
University of Debrecen, Hungary

Introduction In a previous report it was observed that acetazolamide-induced cerebrovascular reactivity was impaired in patients with sepsis-associated encephalopathy without organ dysfunction [1]. The aim of the present work was to assess whether patients suffering from severe sepsis also have these impaired cerebrovascular responses.

Methods Patients fulfilling the criteria of clinical sepsis and showing at least two organ dysfunctions other than the brain were included (n = 14). Nonseptic persons without previous diseases affecting cerebral vasoreactivity served as controls (n = 20). Transcranial Doppler blood flow velocities were measured at rest and at 5, 10, 15 and 20 minutes after intravenous administration of 15 mg/kg BW acetazolamide. The time course of the acetazolamide effect on cerebral blood flow velocity (cerebrovascular reactivity) and the maximal vasodilatory effect of acetazolamide (cerebrovascular reserve capacity (CRC)) were compared among the groups.

Results Mean blood flow velocity in the middle cerebral artery was lower (41.7 ± 13.3 cm/second) in septic patients at rest than in controls (58.2 ± 12.0 cm/second, P <0.01). Pulsatility indices were higher among septic patients at rest (1.56 ± 0.79) than in controls (0.85 ± 0.20, P <0.01). Assessment of the time course of the vasomotor reaction showed that patients with sepsis reacted in similar fashion and extent to the vasodilatory stimulus than did control persons. When assessing the maximal vasodilatory ability of the cerebral arterioles to acetazolamide during vasomotor testing, we found that patients with sepsis reacted to a similar extent to the drug than did control subjects (CRC controls: 46.2 ± 15.9%, CRC SAE: 63.2 ± 28.4%).

Conclusions Cerebral vasoreactivity to acetazolamide is not impaired in patients with severe sepsis. Our data suggest that the reaction of the cerebral arterioles to vasoactive stimuli changes along with the severity of the septic process.

Reference
in-hospital mortality compared with normothermia. The implications of these findings require further study.

Prognostic value of brain glucose levels in the outcome of patients with spontaneous cerebral hemorrhage
DC Papadopoulos1, TC Zafeiriou1, M Mpakopoulou2, G Paraforos1, A Chouvas1, V Christodoulou1, A Komnos1
1General Hospital of Larisa, Greece; 2University Hospital of Larissa, Greece

Introduction
Spontaneous cerebral hemorrhage is a major cause of morbidity and mortality. Bedside, multimodal cerebral monitoring is promising as a diagnosis and prevention of secondary brain damage. The aim of this study is to investigate whether microdialysis parameters can be used as prognostic factors in patients with spontaneous cerebral bleeding, and their association with the long-term outcome.

Methods
Twenty-seven patients with GCS ≤8 were included in the study. Mean age was 57.78 ± 9.94 years. The outcome of the patients was evaluated according to the Glasgow Outcome Scale (GOS) 3 and 6 months post-discharge. Data were evaluated using the SPSS 17.0 and P <0.05.

Results
In a linear statistical model that included all of the microdialysis parameters, only glucose was inversely associated with the patient outcome.

Conclusions
We can use microdialysis to determine cerebral glucose levels, which we found to be associated with patient outcome.

Potential use of transcranial sonography in the sick patient
G Hadjipa1, O Touma2
1Nuffield Department of Anaesthetics, Oxford, UK; 2Oxford Radicliffe Hospitals, Oxford, UK

Introduction
Transcranial sonography (TCS) is used to image brain parenchyma and vasculature. There is a growing body of evidence suggesting a possible imaging role and that Doppler reflects intracranial pressure. The authors conducted a review of this growing literature and propose potential uses of this modality in the assessment of the sick patient.

Methods
A search for papers of special interest was conducted using PubMed and the search items: transcranial, ultrasound, sonography, raised intracranial pressure, haemorrhage, and traumatic head injury. Articles where restricted to adults and considered relevant if they described standardisation, comparisons with other modalities, case studies or explored potential novel uses.

Results
TCS has been standardised and referenced to MRI imaging. It is able to identify intracerebral, and subarachnoid haemorrhage as areas of hyperechogenicity. Compared with CT, it identifies haemorrhage or infarct in 95% of cases. TCS is a reliable quantitative monitor of intracranial pressure. The pulsatility index (PI), a derived index from Doppler flow parameters of the middle cerebral artery, correlates significantly with invasive measures of intracranial pressure (ICP); R = 0.98, P <0.001. A formula can be used to convert the PI into ICP.

Conclusions
TCS has imaging potential, but is unlikely to replace CT for this purpose. The role for TCS in the assessment and monitoring of the sick patient starts where CT fails. It can be used as a quick screening adjunct to the primary survey looking for acute brain injury in those unstable for transfer. It can be used to monitor the size of CT-identified haemorrhage over time or with GCS removing the need for multiple trips to the scanner. It could help identify raised ICP and therefore extra risk from lumbar puncture in the meningitic patient with a normal CT. Finally it allows non-invasive monitoring of ICP in the head-injured patient in whom intubation and sedation are required, but invasive monitoring would be considered excessive.

Correlation of thermal Doppler flowmetry, brain tissue oxygen and microdialysis values in patients with severe subarachnoid hemorrhage and traumatic brain injury: a preliminary report
DC Papadopoulos1, A Komnos1, AS Filippidis2, T Chatzopoulos1, KN Fountas1, G Vrettzakis1, K Paterakis1, D Karangelis1, TK Zafeiriou1
1General Hospital of Larisa, Greece; 2Barrow Neurological Institute, St Joseph’s Hospital and Medical Center, Phoenix, AZ, USA

Introduction
The purpose of this study is to investigate the relationship between continuously monitored regional cerebral blood flow (CBF), brain tissue oxygen (PbrO2) and microdialysis values in subarachnoid hemorrhage and traumatic brain injury patients.

Methods
Advanced multimodal neuromonitoring including monitoring of PbrO2 (Licox; GMS), CBF (QFlow; Hemedex) and brain lactate, pyruvate, lactate/pyruvate ratio, glycerol and glucose values using microdialysis (CMA600; Microdialysis) was performed so far in eight patients with severe subarachnoid hemorrhage (n = 5) and traumatic brain injury (n = 3) for an average of 9.2 days. Additional recorded parameters include ICP, CPP, MAP, CVP, local brain temperature, body core temperature, PCO2 and blood glucose. The cerebral monitoring probes are inserted via a bolt (ICP, PbrO2 microdialysis) and an additional burr hole (CBF). All probes are positioned in the penumbra and location is verified by a brain CT. The study is to be conducted for an estimated total of 30 patients suffering the above pathologies.

Results
The data so far indicate a strong correlation between CBF and PbrO2 values. There seems to be a link between brain glucose levels and CBF values; however, it is not as clear as regards the CBF–PbrO2 correlation. This may be due to the fluctuation of brain glucose because of hyperechogenicity, hyperemia, hypermetabolism or hypometabolism.

Conclusions
This is a preliminary report of a study in human patients with severe subarachnoid hemorrhage and traumatic brain injury. The results indicate correlations of varying significance between the pooled data. We hope that the outcome of our study will be able to clarify the pathophysiology of severe brain injury and guide us in the titration of therapy, as it is needed by each individual patient.

UK practice in management of patients with poor-grade subarachnoid haemorrhage
H Langrick, C Hammell, E O’Callaghan, G Dempsey
University Hospital Aintree, Liverpool, UK

Introduction
Poor-grade subarachnoid haemorrhage patients have historically fared poorly and often been excluded from aggressive treatment. In a recent audit of practice at our ICU only 33% of these patients were transferred to a neurosurgical centre. Recent studies have demonstrated improved rates of survival with good neurological outcomes in patients receiving rapid resuscitation, control of ICP,
early surgery and treatment of cerebral ischaemia [1,2]. We wished to determine national neurosurgical practice with regards to these patients.

Methods We conducted a telephone survey of all UK adult neurosurgical centres. We presented the neurosurgical registrar with two mock-up patients – one grade 5 and one grade 4. We asked questions regarding their transfer policy, surgical and medical management, estimated probability of good outcome (Glasgow Outcome Score 4 or 5), and recommendations regarding management if not for transfer.

Results None of the 30 units had a policy on whom to transfer. Twenty-one out of 30 (70%) advised transfer of the grade 5 patient and all 30 would transfer the grade 4 patient. Good outcome was estimated at 10% for the grade 5 patient (range <5% to 60%) and 50% for the grade 4 patient (range 20 to 90%). Of those recommending transfer of the grade 5 patient, 12 would proceed to CT angiography and endovascular coiling of the aneurysm within 24 hours. Eight centres would wake and reassure the patient and coil if the GCS improved, seven would place a prophylactic extraventricular drain and nine would routinely insert an intracranial pressure monitor. Of the nine centres that would not transfer, all would subsequently reconsider transfer if GCS improved or hydrocephalus developed. No centres recommended insertion of an intracranial pressure monitor in the referring hospital.

Conclusions Treatment of poor-grade subarachnoid haemorrhage remains controversial. In the UK there are no national management guidelines and both recommendations and practice appear to vary considerably between hospitals. Further analysis of national data regarding morbidity and mortality in this patient group is needed. Debate is required to address the question of whether aggressive ICP control is warranted and if so whether this can be provided in a non-specialist ICU.

P325 Increased plasma neutrophil gelatinase-associated lipocalin levels in poor-grade aneurysmal subarachnoid hemorrhage at admission to the ICU
M Terwel, H De Geus, J Bakker, M Van der Jagt
Erasmus MC, University Medical Center Rotterdam, the Netherlands

Introduction Neutrophil gelatinase-associated lipocalin (NGAL) and cystatin C (CysC) are powerful biomarkers predicting acute kidney injury (AKI) in the critically ill. In addition, both NGAL and CysC are related to systemic inflammation, cerebral ischemia and vascular wall damage. Aneurysmal subarachnoid hemorrhage (SAH) is frequently accompanied by cerebral ischemia and has been linked to systemic inflammation. We studied the relationship between NGAL and CysC levels and the severity grade of SAH at ICU admission.

Methods Thirty-six patients with SAH were included. All SAH patients were recruited from a large prospective study on NGAL and AKI between September 2007 and April 2008. Patients with non-aneurysmal SAH (n = 3) and one patient with eGFR <60 ml/minute/1.73 m² were excluded. No subjects had AKI (RIFLE category Risk or more) or suffered from chronic kidney disease (CKD) stage 3 or more. We dichotomised patients into two groups: awake (GCS 15 to 11, n = 30) and comatose (GCS 10 to 3, n = 6), based on the Prognosis on Admission of Aneurysmal Subarachnoid Hemorrhage (PASAH) scale. Statistical comparisons were made with the Mann–Whitney U test and Spearman's rho test.

Results Plasma (p)NGAL was higher in comatose patients (median 144 ng/ml vs. 89 ng/ml, P <0.05). No differences were found in urine NGAL pCyC and urine CyC levels or regular inflammatory parameters (leucocyte count, CRP and temperature). A confounding effect from mechanical ventilation on pNGAL production was excluded using the correlation statistics in intubated and non-intubated patients separately. After correction the correlation between GCS and pNGAL persisted in non-intubated patients (Spearman's rho (non-intubated, n = 29) = −0.36, P <0.05, and (intubated, n = 7) = −0.62, P = 0.069). We found trends towards less positive fluid balance (P = 0.06) during the first 24 hours of admission and higher serum lactate (P = 0.08) in comatose patients, which did not reach statistical significance. Angiography-related contrast exposure was similar in both groups.

Conclusions Our results indicate that poor-grade SAH is associated with increased pNGAL levels at ICU admission not related to AKI, CKD or inflammatory parameters. Alternative mechanisms linking NGAL to SAH grade should therefore be investigated, such as increased sympathetic/catecholamine activity in poor-grade SAH patients [1].

P326 Spontaneous subarachnoid hemorrhage: clinical impact, prognostic value and complications
M Mourelou-Fariña, A Aller-Fernández, P Vidal-Cortés, R Galeiras, M García
University Hospital A Coruña, Spain

Introduction The aim of this study is to identify the characteristics of patients with spontaneous subarachnoid hemorrhage (SAH) and to analyze the complications, treatment, potential risk factors and prognostic value associated.

Methods A retrospective observational study of all patients admitted to our hospital with SAH during 4 years (2006 to 2009). We evaluate the functional outcome using the Glasgow Outcome Scale (GOS) at discharge and 6 months later. We compare variables with the chi-square and Student's t tests. Multiple regression analysis was performed.

Results A total of 168 patients were included: age 57.5 years (SD 14.9), 62.5% women, APACHE II 12 (SD 6.7), Glasgow Coma Scale (GCS) 9.9 (SD 6.5). Punctuation in clinical grading scales was: Hunt-Hess (H-H) 2.8 (SD 1.5); Fisher 3.0 (SD 1.0); World Federation Neurosurgeons Scale (WFNS) 2.8 (SD 1.5). Personal antecedents: arterial hypertension (32.1%) followed by drug use (31.2%). Presentation was headache in 62.1%. We perform CT angiography in 9.6% and arteriography in 78.6% (delay was 1 day). We found no aneurysm in 24.6%. The embolization was complete in 63.4%. The localisation of the aneurysm was more frequent in the anterior communicating artery. Surgical treatment was performed in 2.2%. Complications of SAH: vasospasm 31.5% (managed with triple-H therapy 71.7%), ischemic stroke occurred in 60.4%; 42% rebleeding; hydrocephalus in 23.2%. Mortality risk factors: univariate analysis found age (P = 0.004), worsening control CT (P <0.01), rebleeding (P <0.01), coma (P = 0.02), hydrocephalus (P <0.01), intracranial hypertension (P = 0.002), H-H (P <0.01), Fisher (P <0.01), WFNS (P <0.01). Initial GCS (P <0.01), GOS at discharge to ICU (P = 0.002) and time to embolization (P = 0.02). Multivariate analysis predictors of mortality: GCS at admission and at discharge to ICU (P = 0.013), worsening in control CT (P = 0.004) and length of stay (LOS) in the ICU (P = 0.04). ICU LOS was 10.6 days (SD 9.9) and hospital LOS was 56.7 days (SD 26.3). Global ICU mortality was 29.2% (77.5% brain death).

Conclusions The most frequent complications found were ischemic stroke, vasospasm and hydrocephalus. In our study we found that clinical grading scales predict mortality in univariate analysis. Predictors of mortality in SAH were age, GCS at admission and discharge; control CT, delay to embolization, and complications related to SAH are strong mortality predictors. In most patients, death is related to SAH complications.

P327 Global cerebral edema and brain metabolism after subarachnoid hemorrhage
R Heibrock1, J Claassen1
1Medical University, Innsbruck, Austria; 2Columbia University Medical Center, New York, USA

Introduction Global cerebral edema (GCE) is common amongst poor-grade subarachnoid hemorrhage (SAH) patients and associated with poor outcome. Currently no targeted therapy exists largely due to an incomplete understanding of the underlying mechanisms.

Methods This is a prospective observational study including 39 consecutive poor-grade SAH patients with multimodal neurmonitoring. Levels of microdialysate lactate/pyruvate ratio (LPR), episodes of cerebral metabolic crisis (MC, LPR >40 and brain glucose <0.7 mmol/L), brain tissue oxygen tension (PbtO2), cerebral perfusion pressure (CPP), and transcranial Doppler sonography flow velocities were analyzed.

Results Median age was 54 years (45 to 61) and 62% were female. Patients with GCE on admission (n = 24, 62%) had a higher incidence of MC in the first 12 hours of monitoring than those without GCE (n = 15; 15% vs. 2%, P < 0.05) and during the total time of neurmonitoring (20% vs. 3%, P < 0.001). There was no difference in PbtO2 and CPP between the groups; however, in patients with GCE a higher CPP was associated with lower LPR (P < 0.05). Episodes of crisis were associated with poor outcome (modified Rankin Score 5 or 6, P < 0.05).

Conclusions In poor-grade SAH patients, GCE is associated with early brain metabolic distress. Optimizing cerebral blood flow and homeostasis early after SAH may prove beneficial for patients with GCE.

P328 Incidence, risk factors, and impact on mortality of status epilepticus in sepsis in the United States
J Urtecho, A Seif, M Maltenfort, M Vibbert, W McBride, M Moussouttas, J Jallo, R Bell, F Rincon
Thomas Jefferson University, Philadelphia, PA, USA

Introduction We sought to determine the epidemiology of status epilepticus (SE), prevalence of risk factors and impact on hospital mortality in sepsis in the United States. We hypothesized that SE would be associated with increased mortality.

Methods Data were derived from the National Inpatient Sample from 1998 to 2008. We included patients older than 18 years, with a primary diagnosis of sepsis and SE. Definitions were based on the International Classification of Diseases, Ninth Revision, Clinical Modification Codes (ICD-9). Adjusted incidence rates, prevalence odds ratios (ORs) and 95% confidence intervals (CIs) were calculated. Multivariate logistical models assessed for the impact of SE on hospital mortality.

Results We identified 7,672,551 admissions with diagnosis of sepsis and 7,619 with SE from 1998 to 2008. The population-adjusted rate of sepsis increased from 72/100,000 in 1998 to 250/100,000 in 2008. In septic patients, SE was more common in older patients, in women than men, in urban academic centers than rural centers, in those with respiratory dysfunction and metabolic dysfunction. Total in-hospital mortality fell from 20% in 1998 to 18.1% in 2008, yet the number of deaths increased over the study period. Mortality was highest among SE (OR = 1.7; 95% CI = 1.4 to 1.9) (Figure 1), older patients, men, those with respiratory dysfunction, cardiovascular dysfunction, hematologic dysfunction, metabolic dysfunction, renal dysfunction and hepatic encephalopathy.

Conclusions Our study demonstrates the incidence of SE in sepsis is increasing. Despite a decline in sepsis-related mortality, the presence of SE doubles the risk of in-hospital death. Further study is needed to determine whether detection and treatment of SE will impact mortality.

P329 Seizure attacks in viral encephalitis: influence on a course and outcome
E Rozdziewicz, D Lipowski
Medical University of Warsaw, Poland

Introduction Although occurrence of seizures is common in the course of viral encephalitis, its influence on outcome is less known [1].

Methods The frequency and type of seizures in 229 patients with viral encephalitis were studied. We compared frequency of loss of consciousness, mental disorders, respiratory failure, need for intubation, mechanical ventilation and hospitalization in the ICU, duration of hospitalization and degree of disability at discharge from the hospital according to the Glasgow Outcome Scale (GOS).

Results Patients with seizures (31), significantly more frequent in comparison with patients without attacks (198), presented: mental disorders in 17 (54.83%) versus 62 (31.31%) patients (P < 0.001), loss of consciousness in 28 (90.32%) versus 16 (8%) patients (P < 0.001) and need for intubation, mechanical ventilation and hospitalization in the ICU (34 versus 8 times, P < 0.001). The mean total time of hospitalization was substantially longer in patients with seizures in comparison with the group without them (24.43 vs. 15.9 days, P < 0.001). Patients presenting seizures were prognosticated worse in the scope of good recovery as well as every degree of disability in comparison with a group of patients without attacks (P = 0.001). Outcome after viral encephalitis according to GOS in patients with seizures (31) and without them (198) was as follows: GOS 5 (good recovery) – 19 (61.2%) versus 180 (90.9), GOS 4 (moderate disability) – 7 (22.5%) versus 12 (6%), GOS 3 (severe disability) – 4 (12.9%) versus 5 (2.5%), GOS 1 (death) – 1 (3.2%) versus 1 (0.5%).

Conclusions The occurrence of single generalized seizures, epilepsy and particularly status epilepticus had substantial influence on a course of viral encephalitis and worsened the outcome. Appearance of every type of seizure attack, independent of other clinical symptoms, was a good indicator of the disease severity.

**Incidence, risk factors, and impact on hospital mortality of status epilepticus after subdural hemorrhage in the United States**

A Seith, J Urrutcho, M Maldonfort, M Vibbert, W McBride, M Mousouttas, J Jallo, R Bell, F Rincon

Thomas Jefferson University, Philadelphia, PA, USA

**Introduction** Patients with intracranial hemorrhages are at risk of developing status epilepticus (SE). Small cohort studies have shown that patients with subdural hemorrhages (SDH) may be at risk of developing status epilepticus (SE). In this study, we sought to determine the epidemiology of SE, the prevalence of risk factors, and the impact on hospital mortality in SDH, using a large administrative dataset.

**Methods** Data were derived from the National Inpatient Sample from 1988 through 2008. We searched for admissions with a primary diagnosis of SDH, and SE. Definitions were based on the International Classification of Diseases, 9th Revision. Adjusted incidence rates, prevalence odds ratios (ORs), and 95% confidence intervals (CIs) were calculated.

**Results** Over the 20-year period, we identified 890,153 admissions with primary diagnosis of SDH and 3,214 of SE. The population-adjusted rate of SDH increased from 9/100,000/year in 1988 to 22/100,000/year in 2008, and similarly, the adjusted rate of SE in SDH increased from 0.05/100,000/year in 1988 to 0.11/100,000/year in 2008. In SDH patients, the risk of SE was higher in older than younger patients (OR, 0.99; 95% CI, 0.99 to 1.0; P = 0.06), black than whites (OR, 1.5; 95% CI, 1.2 to 1.9), and in the presence of respiratory failure (OR, 4.3; 95% CI, 3.5 to 5.3), metabolic dysfunction (OR, 1.7; 95% CI 1.3 to 2.26), hematologic disorders (OR, 1.7; 95% CI, 1.3 to 2.26), renal failure (OR, 2.4; 95% CI, 2.1 to 3.26), central nervous system dysfunction (OR, 2.6; 95% CI, 2.1 to 3.26). The total in-hospital mortality fell from 17% in 1988 to 11% in 2008, yet the number of deaths increased over the study period. In-hospital mortality was higher among SE (OR, 1.6; 95% CI, 1.3 to 2.0) older patients (OR, 1.01; 95% CI, 1.01 to 1.01), women (OR, 1.1; 95% CI, 1.01 to 1.1); and in those with respiratory organ dysfunction (OR, 4.9; 95% CI, 4.7 to 5.2), cardiovascular dysfunction (OR, 2.9; 95% CI, 2.7 to 3.2), hematologic dysfunction (OR, 2.2; 95% CI, 2.1 to 2.3), metabolic dysfunction (OR, 2.5; 95% CI, 2.2 to 2.8), renal dysfunction (OR, 2.0; 95% CI, 1.9 to 2.1).

**Conclusions** Our study demonstrates that the incidence of SDH and SE in these patients is increasing in the United States. The risk of SE was higher among older patients, blacks, and in those with respiratory, metabolic, hematological, and renal system dysfunction. Despite a decline in overall SDH-related mortality, SE increased the risk of in-hospital death.

**Electrographic seizures after subarachnoid hemorrhage lead to derangement of brain homeostasis in humans**

J Claassen, A Perotte, D Albers, J Schmidt, B Tu, N Badjatia, K Lee, S Mayer, E Connolly, L Hirsch, G Hiprincsk

*Columbia University Medical Center, New York, USA; Casa de Saúde São José, Rio de Janeiro, Brazil*

**Introduction** This study intends to develop a physiologic fingerprint for nonconvulsive seizures (NCSz). Abnormal electrographic brain activity including NCSz is common after acute brain injury and is associated with poor outcome. Mechanisms underlying this phenomenon are poorly understood but in animals periods of inadequate perfusion during seizures have been documented. In the present study, we hope to gain better understanding of the relationship between abnormal electrographic patterns and brain homeostasis in patients with subarachnoid hemorrhage (SAH).

**Methods** Between June 2006 and June 2010, 51 poor-grade SAH patients underwent multimodality monitoring with microdialysis, brain oxygen tension (pbtO₂), regional cerebral blood flow (rCBF), and intracranial pressure monitoring; 69% (n = 36) also with intracortical EEG (ICE; eight-contact miniature depth electrode). Each minute of EEG (total of 326,513 minutes) was categorized separately into non-ictal, on the ictal–interictal continuum (including periodic discharges at 2 Hz or faster), or seizures. We identified seizure onsets on ICE recordings and extracted the physiologic monitoring data 30 minutes pre and post seizure onset. Physiologic profiles based on standard error of the means plots were generated using high-frequency time series physiologic measurements and interpreted by visual analysis.

**Results** Depth NCSz were recorded in 36% (13/36) of patients with ICE recordings. (depth seizures in 11,017 minutes). NCSz were preceded by an increase in rCBF starting 15 minutes prior to onset of depth NCSz that stayed elevated throughout the observation period. Heart rate, mean arterial, intracranial, and cerebral perfusion pressures were elevated surrounding NCSz. There was a small transient drop in pbtO₂ and a drop in jugular bulb oxygen saturation seen between 1 and 3 minutes following seizure onset. There was a small rise in brain temperature but no change in bladder temperature associated with the NCSz but water temperature of the cooling device dropped following seizure onset.

**Conclusions** These findings confirm in comatose human beings that NCSz detected by ICE are associated with hyperemia, increased metabolism, and possibly brain tissue hypoxia, which serve as surrogates for secondary brain injury. Future research should implement novel approaches for ICU time-series data analysis, evaluate surface seizures, and utilize other surrogates of brain metabolism such as microdialysis.
nonconvulsive status epilepticus (NCSE), and periodic epileptiform discharges (PEDs) in critically ill patients admitted to two mixed medico-surgical ICUs.

**Methods** This was a retrospective study of 58 consecutive ICU patients (mean age 68 ± 23 years old; 50% women) who underwent continuous electroencephalography (cEEG) monitoring for altered mental status. Outcome was assessed as hospital mortality.

**Results** Sixteen patients (28%) were admitted with a primary neurological diagnosis. Mean duration of cEEG was 12 ± 17 hours. Thirty-four patients (59%) were comatose and 32 patients were mechanically ventilated (55%) during cEEG monitoring. Seventeen percent (n = 10) had ESZ, 10% (n = 6) had NCSE, 19% (n = 11) had periodic lateralized epileptiform discharges and 26% (n = 15) had epileptiform discharges.

**Conclusions** In a mixed population of medical and surgical patients, ESZ and NCSE are frequent and associated with increased hospital mortality.

**Nursing environment and delirium in ICU patients**

Il Zaal, LM Peelen, CF Spruyt, J Kesecioglu, AJ Slooter

University Medical Centre Utrecht, the Netherlands

**Introduction** Delirium is a common and serious disorder in the ICU. It has been suggested that the ICU environment may play a role in the development of ICU delirium, but this has never been investigated. In this study we aimed to investigate the relationship between the nursing environment and the duration, incidence and severity of ICU delirium.

**Methods** This prospective observational before/after study was performed in the 32-bed, mixed adult ICU of the University Medical Centre Utrecht. All patients admitted to the ICU were daily assessed on delirium by research physicians. Exclusion occurred when patients remained unresponsive (RASS ≤ -3) during admission or when they were unable to understand Dutch and English. ICU delirium was compared between a ward-like setting, and a setting with single-patient, noise-reduced rooms with diurnal light variation.

**Results** A total of 55 patients (449 observations) were included in the old setting and 75 patients (468 observations) in the new setting. Demographic characteristics were similar for both groups. However, co-morbidity was more severe and emergency admissions were more frequent in the new setting. Delirium occurred in 28 (51%) patients in the old setting versus 34 (45%) patients in the new setting (P = 0.53). After adjusting for confounding, the days patients spent in delirious state decreased with 0.4 days in the new environment (P = 0.005).

**No difference could be observed in the severity of delirium or in the medications prescribed.**

**Conclusions** The number of days patients spent delirious during ICU admission was found to be shorter in patients who were treated in separate noise-reduced rooms with diurnal light variation despite a similar incidence and severity of ICU delirium.

**Development and validation of an eight-step flowchart based on the CAM-ICU: a quick and highly adaptable tool to determine the presence of delirium in ICU patients**

Il Zaal, LM Peelen, D Van Dijk, AJ Slooter

University Medical Centre Utrecht, the Netherlands

**Introduction** Delirium is a frequent and serious disorder in the ICU. Several tools have been developed for standardized delirium testing, of which the Confusion Assessment Method for the ICU (CAM-ICU) is the best validated and most widely used. The main limitations of the CAM-ICU are, however, that it is a very brief assessment of a highly fluctuating disorder, and that the test may lack sensitivity when administered in daily practice. For research purposes, we extended the CAM-ICU.

**Methods** This ongoing prospective validation study was performed in a 12-bed, mixed adult ICU of the University Medical Centre Utrecht. All patients admitted to the ICU were assessed daily and independently on delirium by two means: a junior doctor or neurologist (gold standard); and an eight-item flowchart, based on the CAM-ICU, the reports of the bedside nurses and the administration of haloperidol. Exclusion occurred when patients remained unresponsive (RASS ≤ -3) during admission or when they were unable to understand Dutch and English. With both assessment methods, patients were classified as either awake without delirium, delirious for one or more moments in the past 24 hours, or comatose during the whole past 24 hours.

**Results** A total of 55 patients (35 men, 63.6% mean age 60.0, SD 17.9; mean APACHE II score 18.7, SD 6.1) were included and 379 assessments were made. The form, which excludes patients with neurological pathology for further analysis, showed a sensitivity of 85%, a specificity of 88%, a positive predictive value of 81% and a negative predictive value of 91%.

**Conclusions** While the CAM-ICU is a tool to assess delirium during a brief observation period, this extension can be used to classify the presence of delirium in the previous hours in an ICU where the CAM-ICU is already implemented. The tool appeared to be easy in use and highly adaptable with good test characteristics.

**Delirium assessment in daily critical care with the CAM-ICU: a multicenter study**

MM Van Eijk1, M Van den Boogaard2, AJ Slooter1

1University Medical Center Utrecht, the Netherlands; 2Radboud University Nijmegen Medical Center, Nijmegen, the Netherlands

**Introduction** Delirium occurs frequently in the ICU and is associated with poor outcome. Screening for delirium in ICU patients is recommended by several medical organizations to improve prognosis by early diagnosis and treatment. The Confusion Assessment Method for the ICU (CAM-ICU) has high sensitivity and specificity for delirium when administered by research nurses. However, the test characteristics of the CAM-ICU as performed in routine practice are unclear. The objective of this study is to investigate the diagnostic value of the CAM-ICU in daily practice.

**Methods** Teams of three alternating delirium experts including psychiatrists, geriatricians and neurologists visited 10 ICUs twice. Based on cognitive examination, inspection of medical files and DSM-IV-TR criteria for delirium, the expert teams classified patients as awake and not delirious, delirious or comatose. This classification served as the gold standard to which the CAM-ICU as performed by the bedside ICU nurses was compared. Assessors were unaware of each others’ conclusions.

**Results** Thirteen delirium experts assessed 282 patients, of whom 101 (36%) were classified as comatose and excluded. In the remaining 181 (64%) patients, delirium was diagnosed in 72 by the experts of whom 35 scored CAM-ICU positive. This yielded a sensitivity of 47% (95% CI = 35 to 58%), specificity of 98% (95% CI = 93 to 100%), positive predictive value of 95% (95% CI = 80 to 99%) and negative predictive value of 72% (95% CI = 64 to 79%).

**Conclusions** Specificity of the CAM-ICU as performed in routine, daily practice appears to be high but sensitivity low. The low sensitivity hampers early detection of delirium by the CAM-ICU.

**P337**

**Assessment of delirium in intensive care using the CAM-ICU**

R Shetty, K Reid

BHR Hospitals, London, UK

**Introduction** Delirium remains a common but poorly diagnosed condition in the ICU (1). Delirium is an independent predictor of cognitive decline and mortality (2). The aims of this audit were: to measure the incidence of delirium in our unit; to consider the practicalities of using the CAM-ICU; whether a positive CAM-ICU test would change management; and the attitude of senior intensive care staff regarding the usefulness of CAM-ICU.

**Methods** The CAM-ICU was used for 5 weeks in a mixed general ICU (14 beds) at Queen’s Hospital, Romford. Patients were included into the
Long-term differences on these aspects between critically ill patients with and without delirium during their ICU stay, differences between delirium subtypes on HRQoL and the effect of delirium duration on HRQoL.

Methods At 18 months after ICU discharge an HRQoL survey was sent to 1,292 ICU survivors with (n = 272) and without (n = 1,020) delirium during their ICU stay. The survey consisted of the Short Form (SF)-36, the Checklist Individual Strength (CIS)-fatigue and the Cognitive Failure Questionnaire (CFQ). Covariance analysis was performed to adjust for gender, age, sepsis, APACHE II score and length of stay.

Results A total of 915 (71%) patients responded, of which 171 patients were delirious during their ICU stay (median age 65 (IQR 58 to 85), APACHE II score 17 (IQR 14 to 20)) and 745 patients were not (median age 65 (IQR 57 to 72), APACHE II score 13 (IQR 10 to 16)). After adjusting for covariates, no differences were found between delirious and nondelirious ICU survivors on the SF-36 and CIS-fatigue. However, delirious ICU survivors were significantly more absent-minded (P = 0.02), suffered a more pronounced change in cognitive function compared with their ICU stay (P < 0.01), and their total CFQ score was significantly (P = 0.03) lower compared with ICU survivors that had not been delirious. Hypoactive delirious survivors performed significantly better on several domains of the SF-36 than mixed and hyperactive delirious patients. Duration of delirium tended to correlate with changed health condition after ICU stay (r = -0.15; P = 0.06).

Conclusions ICU survivors that were delirious during their ICU stay experience significantly more cognitive failure than those who were not, even after adjusting for relevant covariates. Hypoactive delirious patients are less affected compared with other subtypes of delirium. Duration of delirium appears to relate to HRQoL.

P339

Effect of rivastigmine as an adjunct to usual care with haloperidol on duration of delirium and mortality in critically ill patients: a multicentre, double-blind, placebo-controlled randomised trial

MM Van Eijk1, KC Roes1, ML Honing2, MA Kuiper3, A Karakus4, M Van der Jagt5, PE Spronk6, WA Van Gool7, RC Van der Mast8, J Kesecioglu9, AJ Slooter1

1University Medical Center Utrecht, the Netherlands; 2Medical Center Alkmaar, the Netherlands; 3Medical Center Leeuwarden, the Netherlands; 4Diakonessenhuis Utrecht, the Netherlands; 5Erasmus Medical Center, Rotterdam, the Netherlands; 6Gelre Hospitals, Apeldoorn, the Netherlands; 7Academic Medical Center, Amsterdam, the Netherlands; 8Leiden University Medical Center, Leiden, the Netherlands

Introduction Delirium is frequently diagnosed in critically ill patients and is associated with adverse outcome. Impaired cholinergic neurotransmission seems to have an important role in the development of delirium. We aimed to establish the effect of the cholinesterase inhibitor rivastigmine on the duration of delirium in critically ill patients.

Methods Patients (aged ≥18 years) who were diagnosed with delirium were enrolled from six ICUs in the Netherlands, and treated between November 2008 and January 2010. Patients were randomised (1:1 ratio) to receive an increasing dose of rivastigmine or placebo, starting at 0.75 ml (1.5 mg rivastigmine) twice daily and increasing in increments to 3 ml (6 mg rivastigmine) twice daily from day 10 onwards, as an adjunct to usual care based on haloperidol. The trial pharmacist generated the randomisation sequence by computer, and consecutively numbered bottles of the study drug according to this sequence to conceal allocation. The primary outcome was the duration of delirium during hospital admission. Analysis was by intention to treat. Duration of delirium was censored for patients who died or were discharged from hospital while delirious. Patients, medical staff, and investigators were masked to treatment allocation. Members of the data safety and monitoring board (DSMB) were unmasked and did interim analyses every 3 months.

Results Although a sample size of 440 patients was planned, after inclusion of 104 patients with delirium who were eligible for the intention-to-treat analysis (n = 54 on rivastigmine, n = 50 on placebo), the DSMB recommended that the trial be halted because mortality in the rivastigmine group (n = 12, 22%) was higher than in the placebo group (n = 4, 5%). A total of 915 (71%) patients responded, of which 171 patients were delirious during their ICU stay (median age 65 (IQR 58 to 85), APACHE II score 17 (IQR 14 to 20)) and 745 patients were not (median age 65 (IQR 57 to 72), APACHE II score 13 (IQR 10 to 16)). After adjusting for covariates, no differences were found between delirious and nondelirious ICU survivors on the SF-36 and CIS-fatigue. However, delirious ICU survivors were significantly more absent-minded (P = 0.02), suffered a more pronounced change in cognitive function compared with their ICU stay (P < 0.01), and their total CFQ score was significantly (P = 0.03) lower compared with ICU survivors that had not been delirious. Hypoactive delirious survivors performed significantly better on several domains of the SF-36 than mixed and hyperactive delirious patients. Duration of delirium tended to correlate with changed health condition after ICU stay (r = -0.15; P = 0.06).

Conclusions ICU survivors that were delirious during their ICU stay experience significantly more cognitive failure than those who were not, even after adjusting for relevant covariates. Hypoactive delirious patients are less affected compared with other subtypes of delirium. Duration of delirium appears to relate to HRQoL.

Impact of delirium in critically ill patients on long-term health-related quality of life and cognitive functioning

M Van den Boogaard1, L Schoonhoven2, A Evers3, J Van der Hoeven4, TH Van Achterberg5, P Pickkers6

1Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands; 2Scientific Institute for Quality of Healthcare, Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands; 3Department of Medical Psychology, Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands

Introduction Delirium is associated with long-term cognitive decline and poor health-related quality of life (HRQoL). Little is known about...
Biomarkers of delirium in critically ill patients

M Van den Boogaard1, L Schoonhoven2, K Quinn3, M Kox1
1Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands; 2Scientific Institute for Quality of Healthcare, Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands; 3Departments of Anesthesia and Critical Care, St Michael’s Hospital, Toronto, Canada

Introduction Delirium occurs frequently in critically ill patients and is associated with disease severity and infection. Although several pathways for delirium have been described, biomarkers associated with delirium in ICU patients are unknown. We examined differences in levels of several biomarkers in matched delirious and nondelirious patients admitted to the ICU.

Methods Delirium in adult ICU patients was diagnosed using the Confusion Assessment Method-ICU (CAM-ICU). Delirious and nondelirious patients were meticulously matched for age, APACHE II score, presence or absence of infection or SIRS criteria, and length of ICU stay at the moment of blood withdrawal. Neurology and trauma patients were excluded. Within 24 hours after the development of delirium, blood was drawn for determination of biomarkers. Covariate analyses were performed using the C-reactive protein (CRP) level to adjust for severity of infection.

Results Fifty delirious and 50 nondelirious ICU patients were included. Levels of TNFα, IL-6, IL-8, MIF, IL-1α, IL-10, MCP-1, PCT, cortisol, and the brain-specific protein amyloid-β truncated-40 were significantly higher in delirious ICU patients. The ratio of amyloid-β 42/40 and truncated 42/40 were significantly lower in delirious compared with nondelirious patients (both \( P \) < 0.05). IL-6 (\( P = 0.057 \)) and MIF (\( P = 0.081 \)) tended to be different in delirious ICU patients.

Conclusions In ICU patients, delirium is associated with significantly increased concentrations of TNFα, IL-8, IL-1α, IL-10, MCP-1, PCT and a decreased ratio of amyloid-β 42/40, even after adjusting for severity of infection. We conclude that several proinflammatory and anti-inflammatory cytokines, PCT and amyloid-β are associated with delirium in ICU patients, and could therefore serve as possible biomarkers.

Introduction Delirium after cardiac surgery is associated with a prolonged length of stay in the ICU, prolonged ventilation time and higher in-hospital mortality. Although the exact pathophysiology of delirium is unknown, both the use of analgesics and the experience of pain have been suggested to be associated with the occurrence of delirium. The aim of the study was to evaluate the association between delirium and analgesics and pain in the ICU.

Methods In a retrospective observational study, pain and delirium scores in patients admitted to the ICU after cardiac surgery via sternotomy during a 2-month period were analyzed. Delirium was scored using the Intensive Care Delirium Screening Checklist (ICDSC, range 0 to 8, ≥4 was deemed delirious). Pain was scored on the Numeric Rating Scale (NRS, range 0 to 10, ≥4 was deemed unacceptable).

Conclusions While delirious patients received significantly less morphine than patients with all ICDSC scores <4 (mean dose 23 ± 8 mg/day vs. 29 ± 13 mg/day, \( P < 0.01 \)), without difference in pain scores between the groups (mean NRS 1.3 vs. 1.4, \( P < 0.3 \) and 34% vs. 28%, \( P < 0.1 \) experienced at least one unacceptable pain score). Delirious patients were older (70 ± 9 vs. 66 ± 11 years, \( P < 0.03 \)), and ventilation time and length of stay in the ICU were significantly longer (26 ± 34 vs. 14 ± 20 hours, \( P < 0.001 \) and 77 ± 53 vs. 48 ± 38 hours, \( P < 0.001 \) respectively). In-hospital mortality was significantly higher for this group (3 vs. 0 patients, \( P < 0.02 \)).

Introduction Secondary brain ischaemia (SBI) usually develops after aneurysmal subarachnoid haemorrhage (SAH) and severe traumatic brain injury (TBI). The current management strategies are based on intracranial pressure-targeted therapy (ICP-targeted) with cerebral microdialysis monitoring (modified Lund concept) or cerebral perfusion pressure-targeted therapy (CPP-targeted) [1–3]. We present a randomised controlled study to compare the two management strategies.

Methods Sixty comatose operated patients with SBI following aneurysmal SAH and severe TBI were randomized into ICP-targeted therapy with cerebral microdialysis monitoring and CPP-targeted therapy groups. Mortality rates in both groups were calculated and biochemical signs of cerebral ischaemia were analysed using cerebral microdialysis. Outcome for cerebral microdialysis was measured as poor outcome (Glasgow Outcome Scale score 1, 2 and 3) or good outcome (Glasgow Outcome Scale score 4 and 5).

Conclusions Patients treated by ICP-targeted therapy with cerebral microdialysis monitoring had a significantly lower mortality rate compared with those treated by CPP-targeted therapy (\( P = 0.03 \)). Patients undergoing cerebral microdialysis with poor outcome had lower mean values of glucose and higher mean values of glycerol and lactate/pyruvate ratio as compared with those with good outcome (glucose: \( P = 0.003 \); glycerol: \( P = 0.02 \); lactate/pyruvate ratio: \( P = 0.01 \)).

There was no difference in the outcome between aneurysmal SAH and severe TBI in the two groups.

Conclusions The ICP-targeted therapy based on modified Lund concept showed better results compared with CPP-targeted therapy in the treatment of comatose patients sustaining SBI after aneurysmal SAH and severe TBI.

Brain midline shift assessment using sonography in neurological care patients

J Motuel, J Bierte, C Cognard, O Fourcade, T Geraerts

University Hospital, Toulouse, France

Introduction

Brain midline shift (MLS) is a life-threatening condition that requires urgent diagnosis and treatment [1]. Bedside MLS assessment with sonography has been proposed as a valuable method in stroke patients [2]. We aimed to validate this method in neurological care patients by comparing it with the brain CT gold standard method.

Methods

This prospective study was conducted in a single neurological care unit. Patients who underwent brain CT scan were included and a concomitant brain sonography with MLS measurement was performed. Using sonography, the midline was determined bilaterally and a concomitant brain sonography with MLS measurement was performed. Using sonography, the midline was determined bilaterally with a 2 to 4 MHz probe using the temporal window by visualizing the third ventricle, with a double hyperechogenic image above the carotid siphon. CT MLS was independently calculated by a specialist in neuroradiology as the maximal difference between the ideal midline and the actual interventricular septum. A significant MLS was defined on brain CT as >0.5 cm.

Results

Fifty-five patients (with a total of 67 paired measured) were included (72% male with a median IGS II of 35.5 ranging from 12 to 65) (35 TBI, eight subarachnoidal hemorrhage, five intracerebral hematoma, seven postoperative care). The mean (± SD) MLS was 0.34 ± 0.34 cm using sonography and 0.48 ± 0.68 cm using CT. The linear regression showed an r value at 0.64 between sonographic and CT MLS (P <0.0001). Bland–Altman plot showed a mean bias of 0.09 cm and three values outside of the limits of agreement (4% of the total measures) (Figure 1). For sonography, the area under ROC curve for the detection of significant MLS was 0.80 (0.68 to 0.89) with a best cut-off value of 0.46 cm with 74% sensitivity and 89% specificity.

Conclusions

MLS measurement using sonography appears to have interesting performances for the detection of significant MLS (that is, >0.5 cm on brain CT). As the regression between sonographic and CT values for MLS was not very strong, and as the agreement between both methods showed relatively large limits of agreements, sonography would not replace the gold standard CT method. However, the bedside estimate could be used as a detection tool in emergency in neurological care patients.

Hypernatremia in neurointensive care: results of a 5-year prospective study

V Spatenkova1, A Kazda2, P Suchomel1

1Regional Hospital, Liberec, Czech Republic; 21st Faculty of Medicine, Charles University, Prague, Czech Republic

Introduction

Hypernatremia is a common medical complication in neurointensive care that is associated with worse outcome. It can be caused by water diuresis due to anti-diuretic hormone insufficiency in central diabetes insipidus (cDI) or from different mechanisms: osmotherapy, furosemide or renal failure. The aim of this prospective study was to analyse hypernatremias in neurointensive care over a period of 5 years.

Methods

We evaluated all hypernatremias defined as serum sodium (SNa+) >150 mmol/l in patients with acute brain disease hospitalised in the neurologic-neurosurgical care unit (NNICU). cDI was diagnosed according to serum and urine osmolality, hourly diuresis, electrolyte-free water clearance (EWC) and response to desmopressin. The remaining hypernatremias were called non-cDI. We compared these groups in Glasgow Coma Scale (GCS) on onset of hyponatremia, incidence of cerebral complications, Glasgow Outcome Scale (GOS) upon discharge from the NNICU and mortality in the NNICU, and EWC.

Results

There were 133 hypernatremic patients (mean SNa+ 154.9 ± 4.5 mmol/l) with mean age 60.6 years; male 72; diagnoses: stroke 88 patients, tumour 19 patients, trauma 19 patients, infection 4 patients, others three patients. The mean GCS on onset of hypernatremia was 9.4 ± 4.3, the mean GOS upon discharge from the NNICU was 2.4 ± 1.2. We diagnosed cDI in 16 patients, the majority (117 patients) was filed as the non-cDI group. Patients with cDI had significantly higher SNa+ (160.1 ± 8.4 mmol/l, P <0.001), diuresis (P <0.001), EWC (P <0.001), mortality in the NNICU (P = 0.012) than patients in the non-cDI group. There were no differences in GCS (P = 0.192), GOS (P = 0.079), cerebral complications (P = 0.809), and anti-edematous therapy (P = 0.221). Patients in the non-cDI group (SNa+ 154.4 ± 3.4 mmol/l) received more diuretics (P = 0.001) and 18 patients had renal failure.

Conclusions

In this study cDI was not a common type of hypernatremia in neurointensive care, but it had higher mortality in the NNICU than other types of hypernatremias, which are caused mostly by diuretics and by renal failure.

Paracetamol-induced skin blood flow and blood pressure changes

M Boyle1, A Lau2, L Nicholson1, M O’Brien1, G Flynn1, D Collins1, W Walsh2, D Bihari1

1Prince of Wales Hospital, Randwick, NSW, Australia; 2University of NSW, Randwick, NSW, Australia

Introduction

Paracetamol given for fever is associated with hypotenison [1]. Spectral analyses (Fourier, wavelet) can be used to identify low-frequency oscillations of skin blood flow (skBF) [2]. The relationship of paracetamol to skBF and blood pressure (BP) in febrile patients was studied.

Methods

Twenty-nine adults, 58 ± 15 years, were treated with enteral or intravenous paracetamol for fever. Forty-one percent (n = 12) were medical, 31% (n = 9) surgical, and 28% (n = 8) neurological. APACHE II score was 17.2 ± 8.3. Frequency domain analyses of the laser Doppler flowmetry (LDF) waveforms of two patients were undertaken. Both patients (A and B) had good LDF waveforms, both increased skBF whilst BP fell in patient B.

Results

Temperature, BP and skBF were recorded 15 minutes prior to paracetamol, at administration (T0) and then every 15 minutes for 60 minutes. Thirty datasets were recorded. Temperature at T0 was 38.7 ± 0.6°C. BP decreased over the study period whilst skBF and cutaneous vascular conductance (CVC = skBF / mean arterial pressure)
increased (repeated-measures ANOVA, \( P < 0.05 \)). Systolic BP decreased (\( P < 0.01 \)) at all post-administration times and was 90 ± 13% of T0 at 60 minutes (Figure 1). CVC was 128 ± 48% of T0 at 60 minutes. Systolic BP fell significantly (\( \pm 15\% \)) in 17 patients (59%). Normalised average power spectral density (PSD) increased substantially in the 0.40 to 2.0 Hz band in patient A, corresponding to an increase in cardiac output (CO). Wavelet scalograms showed increased relative energy for <0.012 Hz (patients A and B) consistent with cutaneous vasodilation and around 0.02 Hz (patient A) consistent with increased sympathetic activity [2].

**Conclusions** Paracetamol induced increases in sBF consistent with its antipyretic action. Changes in PSD and wavelet analysis were consistent with cutaneous vasodilation.

Intravenous paracetamol pharmacokinetics in neonates: a pooled analysis
K Allegaert1, G Palmer2, B Anderson3
1University Hospitals Leuven, Belgium; 2University of Bonn, Germany; 3Royal Children’s Hospital, Melbourne, Australia

**Introduction** The aim of this study was to describe paracetamol pharmacokinetics in neonates, to determine its covariates and suggest a dosing regimen for neonates (28 to 44 weeks postmenstrual age (PMA)).

**Methods** A population PK analysis of paracetamol time–concentration profiles (943 observations) from 158 neonates (27 to 45 weeks PMA) was undertaken using nonlinear mixed-effects models. Data from three earlier published studies involving neonates given either i.v. propacetamol or paracetamol were pooled with newly collected observations during repeated i.v. paracetamol administration (\( n = 60, 343 \) observations, PARANEO study) [1-3].

**Results** A two-compartment linear disposition model was used. Population parameter estimates (between-subject variability, %) were central volume (V1) 51.9 (21.6%) l/70 kg, peripheral volume of distribution (V2) 22.7 l/70 kg, clearance (CL) 5 (40%) l/hour/70 kg and inter-compartment clearance (Q) 16.2 l/hour/70 kg. About one-half (60.9%) of the overall CL variance is predictable from covariates. Weight was used to predict size and this was the major covariate (57.5%). Clearance expressed as mg/kg/hour increases only slightly with PMA (0.138 at 28 weeks, 0.167 l/hour/kg at 44 weeks PMA), contributing only 2.2% of variance within this cohort. Unconjugated bilirubin contributed only an additional 1.2% of variance.

**Conclusions** An increased volume of distribution supports the use of a loading dose when instigating paracetamol therapy in neonates while size is the major covariate of clearance. Clearance matured slowly in this cohort and a mean paracetamol serum concentration of 11 mg/l is achieved in neonates (28 to 44 weeks) given a standard dose of paracetamol of 10 mg/kg/6 hours. Based on these estimates, we suggest a loading dose of 20 mg/kg followed by 6-hourly dosing (10 mg/kg) within the age range evaluated.

**P347**
Tramadol and O-demethyltramadol disposition in humans: a pooled study
K Allegaert1, U Stamer1, B Anderson2, S Holford3, A Rochette4, I Troconiz5, R Pedersen6, N Holford1
1University Hospitals Leuven, Belgium; 2University of Bonn, Germany; 3Royal Children’s Hospital, Melbourne, Australia; 4Hopital Lapeyronie, Montpellier, France; 5University of Navarra, Pamplona, Spain; 6University of Southern Denmark, Odense, Denmark

**Introduction** To study the use of size, maturation and CYP2D6 genotype score as predictors of i.v. tramadol (M) disposition throughout human life, published observations were pooled [1-6].

**Methods** M and O-demethyltramadol (M1) observations in 295 subjects (25 weeks postmenstrual age to 84.8 years) were available for population PK analysis (NON-MEM, two-compartment model for M and two additional compartments for M1). Covariates were weight, age, sex, disease (healthy/patient) and CYP2D6 genotype score. A sigmoid maturation model was used to describe changes in M (CLPO + CLPM), M1 formation (CLPM) and M1 elimination (CLM0) clearance. Phenotype-based and genotype-based models were used to distinguish poor CLPM subjects.

**Results** Differences in M disposition between children and adults were largely accounted for by maturation and size. CLPM (TMSO 40.3 weeks, Hill 0.09) and CLPO (TMSO 39.1 weeks, Hill 5.8) display fast maturation, while CLM0 matures slower. The phenotype-based mixture model estimated that 8.6 were slow metabolizers (18.3% of normal CLPM). Genotype-based estimates were also lower (68%) but not all subjects with a low CYP2D6 score were in the poor metabolizer group.

**Conclusions** Maturation of M elimination occurs early with 50% of adult values at full-term age. Maturation and age are key predictors, while CYP2D6 genotype score only explains some of the variability in M disposition.

Bispectral index monitoring reduces sedative and vasopressor requirements during percutaneous tracheostomy
P Hampshire, A Guha, I Weiters, J Murphy, L Poole
Royal Liverpool and Broadgreen University Hospital, Liverpool, UK

**Introduction** Bispectral index (BIS) monitoring measures depth of anaesthesia, using electroencephalography (EEG). It has been validated against sedation scales used in intensive care. We hypothesized that using BIS during percutaneous tracheostomies would reduce sedation doses, resulting in fewer episodes of haemodynamic instability.

**Methods** Patients undergoing percutaneous tracheostomy were randomised to the control or intervention groups. Norepinephrine was administered to prevent a fall of more than 20% in mean arterial blood pressure. Patients in the control group were sedated with a propofol infusion at a dose chosen by the operator. All personnel performing the tracheostomy were blinded to the BIS score. In the intervention group, patients were sedated with a propofol infusion adjusted so that the BIS
was maintained between 45 and 60. Patients with encephalopathy or brain injury, and patients who had received sedative drugs other than alfentanil and propofol were excluded. All patients or their advocates gave written, informed consent. The primary outcome was the number of episodes of haemodynamic instability. Secondary outcomes were the dose of propofol administered to patients, BIS scores, time of recovery from sedation, total norepinephrine administered to patients, and time taken to do the procedure.

**Results** Twenty patients entered the study. Results are presented as mean ± SD. There was no significant difference in the incidence of hypotension (4.5 ± 6.8 events and 5.6 ± 6.9 events in control and intervention groups, respectively, \( P = 0.25 \)). There were fewer episodes of hypertension in the intervention group (2.5 ± 4.6 events in the control group and 0.9 ± 2.2 events in the intervention group) \( (P = 0.12) \). The dose of propofol and norepinephrine dose were lower in the intervention group: 5.4 mg/kg/hour cf. to 6.8 mg/kg/hour for propofol \( (P = 0.21) \); 0.05 μg/kg/hour cf. to 0.09 μg/kg/hour for norepinephrine \( (P = 0.14) \). The mean time to waking was significantly shorter in the intervention group (54 minutes) as compared with that in the control group (96 minutes), \( P = 0.04 \).

**Conclusions** BIS monitoring did not significantly reduce sedation requirements, or improve haemodynamics during percutaneous tracheostomy. Although there was a trend to both reduced sedation requirements and improved haemodynamic stability. The time to waking was significantly reduced.

**P349 How is sedation provided for percutaneous dilatational tracheostomy in English ICUs?**

P Hampshire, L McCrossan
Royal Liverpool and Broadgreen University Hospital, Liverpool, UK

**Introduction** Percutaneous dilatational tracheostomy (PDT) is commonly performed at the bedside in the ICU. Patients in the ICU often have multiple organ dysfunction, causing alterations in drug effects and metabolism. Alterations in sedative drug handling may make them vulnerable to awareness during PDT. Up to 40% of patients in the ICU report some awareness whilst receiving neuromuscular receptor blocking drugs [1] – these drugs are usually employed when performing PDT. Depth of anaesthesia monitoring may prevent awareness and has been reported some awareness whilst receiving neuromuscular receptor blocking drugs. Alterations in sedative drug handling may make them vulnerable to awareness during PDT. A bispectral index monitor (BIS), the Narcotrend Index and the Depth of anaesthesia monitoring may prevent awareness and has been reported some awareness whilst receiving neuromuscular receptor blocking drugs. Alterations in sedative drug handling may make them vulnerable to awareness during PDT.

**Methods** We contacted 240 adult ICUs in England by telephone. Two hundred and twenty-four units (93%) participated.

**Results** Two hundred and fourteen units (95%) perform PDT as their first-choice technique. Units that do not practice PDT \( (n = 10, 5\%) \) perform open surgical tracheostomy. Most ICUs use simple infusions of propofol via standard infusion pumps during PDT \( (n = 202, 94\%) \), and give additional boluses of propofol if necessary. In seven units \( (3.3\%) \) anaesthesia is provided using intermittent boluses of propofol, without a background infusion. This may be of concern given that one study reported awareness during rigid bronchoscopy [3] and all the patients who reported awareness were anaesthetized using intermittent boluses of propofol. Nine units \( (4.2\%) \) reported using a BIS during PDT. Three ICUs have used a BIS on a trial basis, but have discontinued. One reason given for discontinuing use of a BIS was that it ‘made no difference to the amount of sedation’ during PDT.

**Conclusions** Depth of anaesthesia monitoring is not widely used in English ICUs during PDT. It is unclear whether a BIS is effective for monitoring depth of anaesthesia during PDT, and further studies are needed to clarify this.

**P350 Meta-analysis of detection of respiratory events during procedural sedation**

JW Waugh, YA Khodneva, CA Epps
University of Alabama at Birmingham, AL, USA

**Introduction** The use of procedural sedation and analgesia (PSA) has increased in frequency and scope, including emergent settings inside as well as outside the hospital. Although end-tidal CO₂ (EtCO₂) monitoring is routinely used during general anesthesia to monitor ventilatory status, this is not the case for PSA. Pulse oximetry and visual inspection, both with inherent limitations, represent the current standards of care for monitoring ventilatory status during PSA. EtCO₂ monitoring may be a preferable method for detecting alveolar hypoventilation and preventing hypoxemia during PSA but is not widely used in this setting. Our study objective was to determine whether capnography, in addition to standard monitoring improved detection of respiratory events compared with standard monitoring alone.

**Methods** A literature search was conducted using the electronic databases PubMed, CINAHL, and Cochrane Library (Cochrane Reviews, CENTRAL) for studies published between 1995 and 2009 reporting adverse respiratory events during procedural sedation and analgesia with clearly defined EtCO₂ threshold, clear study design, P-value calculation, similar outcome and predictor variable definitions, and binary independent and dependent variable raw data. To limit threats from variations in practice, only reports of adults in the USA were included. Five such studies were evaluated independently. A meta-analysis of these studies was performed.

**Results** During PSA, cases of respiratory depression were 17.6 times more likely to be detected if monitored by capnography, versus cases not monitored by capnography (95% CI, 2.5 to 122.1; \( P < 0.004 \)).

**Conclusions** This analysis suggests that EtCO₂ monitoring is an important addition for detecting respiratory depression during PSA.

**P351 Decreased postoperative nausea and vomiting with dexmedetomidine after off-pump coronary artery bypass grafting**

H Okawa, T Oro, E Hashiba, T Tsuho, H Ishihara, K Hirota
Hirosaki University Graduate School of Medicine, Hirosaki, Japan

**Introduction** Postoperative nausea and vomiting (PONV) is one of the factors that affect the quality of postoperative patient care. We would like to report possible antiemetic effects of dexmedetomidine (DEX), a selective α₂-agonist sedative, in patients after off-pump coronary artery bypass grafting (OPCAB).

**Methods** Local Research Ethics Committee approval and written informed consent from patients or next of kin were obtained before this study. Patients after OPCAB were allocated into two groups (sedated with DEX; DEX(+), \( n = 123 \) and no sedation; DEX(-), \( n = 134 \)). The incidence of PONV, postoperative morphine consumptions and amount of gastric fluid drained via a nasogastric tube were compared in the two groups.

**Results** There were no significant differences in the patients’ profiles and intraoperative opioid consumptions. Eight patients in the DEX(+) group had PONV whereas 35 patients had PONV in the DEX(–) group \( (6.5\% \text{ vs. } 26.1\%, \ P < 0.01) \) during a postoperative observation period of 12.5 (3.2) and 11.8 (2.4) hours, respectively \( (\text{mean (SD)}). \) The ratio of patients who required morphine for postoperative pain relief was lower in the DEX(+) group than the DEX(–) group \( (67.5\% \text{ vs. } 83.6\%, \ P < 0.01) \), presumably due to analgesic effects of DEX. Analysis of individual patients revealed that five out of eight patients and 12 out of 35 patients had PONV after morphine use in the DEX(+) and DEX(–) groups, respectively. Repeated analysis without those patients revealed the same tendency \( (3.4\% \text{ vs. } 18.2\% \text{ had PONV in the DEX(+) and DEX(–) groups, respectively; } P < 0.01) \) as obtained in all the patients, revealing the same tendency (3.4% vs. 26.1% had PONV in the DEX(+) and DEX(–) groups, respectively; \( P < 0.01) \) as obtained in all the patients. There were no significant differences in the amount of gastric fluid drained via a nasogastric tube between groups.
Conclusions DEX is reported to inhibit gastrointestinal transit and gastric emptying like morphine. According to this report, the decreased incidence of PONV in the DEX(+) group in our study is not likely to be caused by peripheral effects of DEX on the gastrointestinal tract. It is widely recognized that morphine induces PONV, and we analyzed the incidence of PONV without patients who had any suspicion of morphine-induced PONV, obtaining the same result. According to these considerations, we would like to conclude that DEX could have antiemetic effects per se.

Heart rate variability during infusion of dexmedetomidine
T Imabayashi, K Ikoma, T Kikuchi, Y Kikasih, T Kanmura
Kagoshima University Hospital, Kagoshima, Japan

Introduction Dexmedetomidine is an α₂-agonist, used for sedation in the ICU, although much remains to be learned about the effects on the autonomic nervous function. We therefore investigated the real-time monitoring of heart rate variabilities.

Methods From May through November 2010, 20 patients were selected if they were treated on total mechanical ventilatory support and they were treated with continuous infusion of dexmedetomidine in our ICU. The exclusion cases were with arrhythmia or pacemaker or other treatment during the measure time. Heart rate (HR) variability analysis was recorded using the MemCalc system (MemCalc/Tonami16C; Suwa Trust, Tokyo, Japan). The spectral bands were 0.04 to 0.15 Hz (low frequency (LF)), 0.15 to 0.40 (high frequency (HF)) and others. The HF component was an indicator of sympathetic balance, and LF/HF was that of parasympathetic balance. We measured the HR, CV-RR, HF, LF/HF, systemic blood pressure (SBP), CV-SBP, SBP-HF and SBP-LF/HF. The CV-RR was SD of RR intervals, and the CV-SBP was SD of systemic blood pressure. We compared them between before and after 30 minutes administration of dexmedetomidine. The Wilcoxon signed-ranks test was used to compare the differences. P < 0.05 was considered statistically significant.

Results The HR was significantly decreased (P = 0.017), and the CV-RR was in a tendency of decrease (P = 0.085). Although the SBP was not significantly changed, the CV-SBP was significantly decreased (P = 0.038). Other parameters (HF, LF/HF, SBP-HF and SBP-LF/HF) were not significantly changed.

Conclusions We investigated the autonomic nervous functions in 20 patients treated with dexmedetomidine. The HR and the CV-SBP were significantly decreased. Dexmedetomidine was affected with depression of sympathetic nerve system to the HR, the CV-RR and CV-SBP.

Pharmacokinetics of long-lasting, high-dose dexmedetomidine infusions in critically ill patients
T Iirola1, R Aanta2, R Laati2, E Kentala1, M Lahtinen1, A Wighton2, C Garratt2, T Ahtola-Sätilä1, KT Olkkola1
Turku University Hospital, Turku, Finland; 2Orion Pharma, Nottingham, UK

Introduction The aim of this study was to characterize the pharmacokinetics of long dexmedetomidine (dexmed) infusions and assess the dose linearity of high doses.

Methods Dexmed was infused to critically ill intensive care patients for 12 hours using a constant infusion rate determined by the prestudy dose of propofol or midazolam. After the first 12 hours, the infusion rate of dexmed was titrated between 0.1 and 2.5 μg/kg/hour using prefixed levels to maintain sedation in range of 0 to –3 on the Richmond Agitation–Sedation Scale (RASS). Dexmed was continued as long as required to a maximum of 14 days. Safety and tolerability were assessed by adverse events, heart rate, blood pressure, ECG and laboratory tests.

Results Dexmed concentration profiles of the 13 patients during the infusion and 48-hour follow-up are depicted in Figure 1. The geometric mean values (CV%) for length of infusion, dexmed half-time, clearance and volume of distribution (elimination) were 91 hours (117%), 3.7 hours (38%), 41 l/hour (47%) and 223 l (35%), respectively. There was a linear relationship (r² = 0.95; P < 0.001) between the areas under the dexmed plasma concentration–time curves and cumulative doses of dexmed. All but one patient needed propofol to keep the RASS value in the target zone. The most common adverse events were tachycardia, hypotension and hypertension.

Conclusions The pharmacokinetics of dexmed was linear up to the dose of 2.5 μg/kg/hour. Despite the high dose and long-lasting infusions, safety findings were as expected for dexmed and the patient population.

Figure 1 (abstract P353). Dexmedetomidine concentration profiles of the 13 patients.

P354
Hemodynamic, metabolic and inflammatory effects of dexmedetomidine in a pig model of septic shock
P Carnicelli1, D Fantoni1, D Otsuki1, A Monteiro Filho1, M Kahvegian2, J Noel-Morgan3, J Auler Jr2
1Faculdade de Medicina Veterinária e Zootecnia da Universidade de São Paulo, Brazil; 2Faculdade de Medicina da Universidade de São Paulo, Brazil; 3Critical Care 2011, 15(Suppl 1):P354 (doi: 10.1186/cc9774)

Introduction The use of dexmedetomidine to achieve sedation, analgesia and mechanical ventilation has increased in critically ill patients, although little is known about its effects in septic shock. The aim of this study was to assess hemodynamic, metabolic and inflammatory effects of dexmedetomidine in a pig model of septic shock.

Methods Eighteen pigs were anesthetized, mechanically ventilated and randomly allocated into three groups of six animals: sham group, shock group (intravenous infusion of live Escherichia coli over 1 hour) and shock+dex group (E. coli + bolus and constant rate infusion treatment with dexmedetomidine). Both shock groups received fluid therapy with lactated Ringer’s (LR) and norepinephrine to reach central venous pressure of 8 to 12 mmHg and mean arterial pressure ≥65 mmHg. T0 was considered the end of bacterial infusion and animals were monitored hourly for 240 minutes. Hemodynamic parameters were assessed with a pulmonary artery catheter and femoral arterial catheter. Blood gases, intestinal tonometry and inflammatory cytokines were also measured. Two-way ANOVA and Tukey test were used for statistical analysis (P < 0.05).
Results  E. coli infusion resulted in cardiovascular collapse, acute lung injury and metabolic acidosis. At T0, oxygen consumption was significantly greater in the shock+dex group (149.9 ± 25.6 ml/minute/m²) than in the shock group (111.5 ± 21.6 ml/minute/m²), as was Pr–PaO₂ (53 ± 14 mmHg and 35 ± 11 mmHg, respectively). At T180, SvO₂ in the shock+dex group was statistically lower than in the shock group (62.5 ± 9.0 vs. 74.2 ± 9.1%, respectively). At T240, cardiac index in the shock+dex group was lower than that in the shock and sham groups (2.6 ± 0.5 vs. 3.6 ± 1.7 vs. 4.7 ± 1.1 ml/minute/m², respectively) while the oxygen extraction rate was larger in the shock+dex group (43 ± 29%) than in the shock group (25 ± 11%). TNFα levels were similar in both groups. Although plasma levels of IL-1β, IL-6 and IL-10 were elevated in the shock group, there was no statistical significance with the shock+dex group. No statistical difference was found in treatment with LR or norepinephrine, nor in urine output.

Conclusions  Dexmedetomidine is likely to cause a mismatch between oxygen delivery and consumption by affecting microcirculation in critically ill patients, despite treatment with crystalloids and vasopressors. Its effects on the inflammatory response remain unclear.

Dexmedetomidine improves attention and recall in agitated critically ill patients
MM Mirski, RG Gill, PM Murakami, CT Thompson, JL Lewin
Johns Hopkins Medicine, Baltimore, MD, USA

Introduction  It is of clinical interest to maintain patient comfort in the ICU and yet preserve their intellectual function, arousal and interaction. Recently, dexmedetomidine (DEX) was demonstrated in the ANIST Trial to preserve intellectual function as compared with propofol (PRO) when used as conscious sedation in both agitated neurologically intact and brain-injured critically ill patients [1]. The purpose of this study was to further understand whether selective areas of cognition were specifically affected by PRO and DEX through sub-analysis of the Trial’s results on each of the five subscales of the Adapted Cognitive Exam (ACE).

Methods  We preformed a post-hoc analysis of the prospective randomized, double-blinded cross-over designed ANIST trial that compared cognitive differences between PRO and DEX on the validated 100-point Hopkins ACE. This current study further investigated differences by analyzing the five subscales of the ACE, which consist of Orientation, Language, Registration, Attention/Calculation and Recall. Analysis included a generalized estimating equations approach to estimate differences between drugs while accounting for within-subject correlation arising from the crossover design. We examined unadjusted and adjusted models both with and without inclusion of potential period effects. We also accounted for period effects, and robust variance estimates were used to calculate standard errors.

Results  Sedation with PRO diminished adjusted scores on four of the ACE subscales (P <0.01), while DEX improved adjusted scores on two of the subscales (Attention/Calculation 2.33, 95% CI: 0.11 to 4.59; Recall: 2.03, 95% CI: 0.03 to 4.04). The other estimates for the effects of PRO and DEX on the ACE subscales were not statistically significant using a significance level of 0.05. The positive and significant difference in the change of ACE score between DEX versus PRO held up in all of the subscales.

Conclusions  Our findings indicate that DEX not only preserved but also improved Attention/Calculation and Recall in ICU patients who were awake, agitated and required sedation. This was evident by higher mean ACE subscale scores when compared with their baseline. Our findings suggest that DEX improved overall cognitive function without significantly compromising the ability to focus and recall events.

Skin conductance variability in ICU patients: an observational study of the relation to pain and Motor Activity Assessment Scale level
AC Günther1, AR Schandl1, H Storm1, P Bosi, PV Sackey2
1Karolinska Institutet, Stockholm, Sweden; 2Rikshospitalet University Hospital, Oslo, Norway

Introduction  Many patients describe pain and other adverse feelings from the ICU environment which impacts long-term psychological morbidity. Presently no objective method for detecting pain or distress is available. Skin conductance variability has been investigated as a monitor of perioperative pain. The method has not been studied in adult ICU patients.

Methods  Twenty-five (13 intubated and 12 non-intubated) patients were included in this observational study. Patients were monitored with the MED-STORM Stress Detector for 1 hour of intensive care treatment and care. Skin conductance variability (number of skin conductance fluctuations per second (NSCF)) was measured and patients were observed in parallel during rest and during procedures and staff–patient interactions. The sedation–agitation level was monitored with the Motor Activity Assessment Scale. Pain was monitored with the Numeric Rating Scale (0 to 10) in combination with observation of expressions of pain in patients unable to communicate verbally.

Results  In non-intubated patients, NSCF values were low when patients were unstimulated and comfortable and increased with increasing stimulation but also with increasing agitation without any apparent pain. The highest NSCF values were noted during combined pain and agitation. In intubated patients, a similar pattern was observed but with generally lower values, most likely due to sedation. Sensitivity and specificity of NSCF at a cut-off value >0.13 for detecting expressed pain/discomfort were 74% and 55% for non-intubated patients and 61.5% and 68% for intubated patients.

Conclusions  Skin conductance variability increases in critically ill patients with increasing stimulation but is also affected by the level of sedation/agitation, making the method unsuitable for detecting pain alone in critically ill patients, but possibly of value to more generally monitor emotional stress with different etiology. Further studies of the method in critically ill patients, over longer time and with validated pain instruments are warranted.

Conflicts of interest  HS is a co-owner of Med-Storm AS, the company responsible for the production and distribution of the Med-Storm Stress Detector. The other authors declare that they have no conflicts of interest.

Change in hypnotic sedative choice over time as a surrogate marker of improved performance
T Hughes, F Hanks, P Hopkins
Kings College Hospital, London, UK

Introduction  Daily sedation holds, particularly when combined with protocolised spontaneous breathing trials, are one of the only strategies available to intensivists that produce an outcome benefit [1]. This evidence has also provoked a renewed interest in the choice of both hypnotic and analgesic agents. Midazolam is known to produce unpredictable awakening and may prolong time to extubation when infusions continue longer than 48 to 72 hours. In contrast, propofol may enhance the benefit to critically ill patients of the daily sedation hold due to its pharmacokinetic properties [2]. This study examines the hypothesis that the ratio of propofol/midazolam use can be used as a surrogate marker of good practice and utilises the potential of the pharmacy procurement database.

Methods  The amount of propofol and midazolam supplied in grams per month was obtained from the pharmacy database for both the surgical and medical critical care units for the period April 2006 to July 2009. These data were compared with the number of monthly admissions, average monthly length of stay, APACHE II score (May 2008 to July 2009) and standardised mortality rate (SMR) for that period. SigmaPlot 11.0 was used to determine statistical significance.
Results There was a statistically significant increase in propofol use per patient ($r = 0.512; P = 0.0007$) and reduction in midazolam use per patient ($r = -0.384; P = 0.014$) between April 2006 and July 2009. The mean ± SD monthly admission rate was 142 ± 15.3 patients. The use of propofol/midazolam was independent from length of stay and APACHE II score. Statistical significance was not reached when correlating propofol/midazolam use to fall in SMR (1.11 to 0.77) due to the limited number of data points.

Conclusions Although a clear relationship between reduced midazolam use and improved outcome could not be demonstrated, information from the pharmacy database remains an important means to review prescribing practice. Monthly supply may not always accurately reflect use but over time will indicate significant changes in practice such as the reduced use of midazolam at this institution.

What happens to all that propofol during prolonged sedation?
N Cowley, TH Clutton-Brock
University Hospital Birmingham, UK

Introduction There are few published data on the pharmacokinetics of propofol infusion for prolonged periods in critical care. Propofol is frequently infused for days or weeks in critically ill patients with organ dysfunction. We aimed to determine whether propofol concentrations in critically ill patients are predictable during constant rate infusion, and whether significant organ failure might lead to accumulation when compared with conventional pharmacokinetic models.

Methods We compared blood propofol levels with total dose and duration of propofol infusion in 53 samples from 43 patients on a mixed critical care unit undergoing prolonged sedation. Estimated propofol concentration was calculated using the Marsh algorithm. The Richmond Agitation Scale at the point of propofol measurement was recorded, and the Sequential Organ Failure Assessment (SOFA) score was recorded for assessment of its impact on propofol levels.

Results Propofol was infused for a mean of 33 hours (14 to 44 interquartile range). The mean measured propofol concentration was 1.37 μg/ml (range 0.29 to 2.60). There was fairly good correlation between estimated propofol concentrations (based on the Marsh model) and measured levels with a $R^2$ value of 0.500, shown in Figure 1. The level of organ failure did not impact significantly on the accuracy of predicted propofol levels.

Conclusions We were able to demonstrate a correlation between predicted propofol levels and those measured in blood. Predicted propofol levels were on average lower than measured levels, suggesting a reduced capacity to metabolise propofol in critical illness, although this effect was not marked, and we were unable to demonstrate an association between severity of organ failure and deviation of measured from predicted propofol levels.

Acknowledgements The authors thank Sphere Medical Ltd for use of the novel blood propofol analyser.

Psychological long-term effects of a no-sedation protocol in critically ill patients
T Strom, M Stylsvig, P Toft
Odense University Hospital, University of Southern Denmark, Odense, Denmark

Introduction A protocol of no sedation has been shown to reduce the time patients receive mechanical ventilation and reduce intensive care and total hospital length of stay [1]. The long-term psychological effect of this strategy has not yet been described.

Methods We contacted all surviving patients who had been randomized to our original trial that compared a no-sedation strategy with a traditional strategy of sedation and daily wake-up trial. Patients were offered a follow-up interview with a neuropsychologist. The neuropsychologist was blinded to the randomized treatment. All patients were assessed with the same validated psychological tests. Post-traumatic stress disorder (PTSD) was evaluated with three tests: Revised Impact of Event Scale, State Anxiety Inventory Scale and Post-Traumatic Stress Syndrome 10-Questions Inventory scale (PTSS-10). The generic quality of life was evaluated using the Medical Outcomes Study 36-item short-form health survey (SF-36). Depression was evaluated using the Beck Depression Inventory-2 score (BDI-II). Patients were also assessed with a modified version ICU memory tool.

Results A total of 26 patients were interviewed (13 from each group). The time span between randomization and interview was 2 years (no-sedation group 1.78 (1.46 to 2.10) years vs. sedated group 2.04 (1.55 to 2.29) years, $P = 0.32$). No difference was found with respect to baseline data. Very few patients suffered from PTSD and no significant difference was found between the two groups. No difference was found with respect to generic quality of life (SF-36). A very low rate of depression was found in both groups with no significant difference. The modified ICU memory tool showed that two-thirds of patients from both groups had experienced nightmares during their ICU stay. Very few patients remembered pain or breathing difficulties in the ICU (NS).

Conclusions Our data disprove the popular supposition that a protocol of no sedation applied to critically ill patients undergoing mechanical ventilation increases the risk of long-term psychological sequelae after intensive care compared to standard treatment with sedation. With the reduced ventilator days, reduced ICU and hospital length of stay, this psychological follow up further supports the benefits from a no-sedation strategy applied to critically ill patients undergoing mechanical ventilation.

Cannabinoid receptor-1 inhibition causes anesthetic-induced excitation in septic rats
R Küchner et al.
Dalhousie University, Halifax, Canada

Introduction In systemic inflammation and sepsis, the endocannabinoid system is upregulated [1]. While it is known that neuronal
cannabinoid signalling via cannabinoid receptor-1 (CB1) in the central nervous system represents an intrinsic neuroprotective response [2] and exerts anti-epileptic activity [3], inhibition of CB1 (CB1inh) has been suggested as an experimental target for sepsis therapy [4]. We studied the effects of CB1inh in rats with experimental sepsis during anesthesia induction with pentobarbital.

**Methods** Five groups of Lewis rats were included in the study: Group 1 – sham-operated controls treated with CB1inh (AM281, 2.5 mg/kg i.v., n = 12), Group 2 – animals with colon ascendens stent peritonitis (CASp)-induced sepsis treated with CB1inh (n = 12). As additional control groups, we administered in CASP animals the CB1 agonist ACEA (2.5 mg/kg i.v.; Group 3; n = 4) or the solvent DMSO (Group 4; n = 4). In Group 5 we administered 50 mg/kg ketamine for induction of anesthesia 14 hours following the CASP treated by CB1inh. All other groups received a standard dose of pentobarbital (40 mg/kg i.v.) 14 hours following CASP procedure.

**Results** In five out of 12 septic animals (42%) with CB1inh (Group 2) we observed tonic–clonic seizures immediately after induction of anesthesia with a standard dose of pentobarbital. In sham-operated animals (Group 1) or CASP animals without CB1inh (Group 4) we did not observe anesthetic-induced excitation. Replacement of the barbiturate anesthesia induction with pentobarbital.

**Conclusions** CB1 inhibition in sepsis may increase the incidence of anesthetic-induced excitation and reduce CB1-mediated intrinsic neuroprotective response.

Introduction of a remifentanil-based analgo-sedation protocol leads to a reduction of duration of mechanical ventilation and ICU stay in critically ill patients

**J Van den Bosch, J Van Bommel, J Bakker, D Gommers**
Erasmus MC, Rotterdam, the Netherlands

**Introduction** Conventional sedation strategies in the ICU are based on the use of propofol or benzodiazepines for sedation in combination with morphine or other opioids for analgesia. An alternative strategy is based on analgo-sedation with remifentanil, a potent and very short-acting opioid agent. However, evidence is scarce that such a strategy is more efficacious.

**Methods** In January 2010 we introduced a remifentanil-based analgo-sedation protocol in our 32-bed academic general ICU. To evaluate the efficacy, we performed a retrospective comparison of all patients admitted between 1 April and 30 June 2010 with a control group consisting of patients admitted between 1 February and 30 September 2009 who underwent a conventional sedation strategy. Exclusion criteria were mechanical ventilation <24 hours, brain trauma, any other neurologic pathology, and moribund.

**Results** In total, 596 patients were selected in the conventional group (C) and 214 in the remifentanil group (R); after exclusion, group C consisted of 163 patients and group R of 70 patients for analysis. Both groups were identical in age, sex and APACHE II score. The mean duration of mechanical ventilation was significantly lower in group R (P = 0.01); time to successful detubation was significantly shorter in group R (log-rank P = 0.0026, HR = 0.57 (0.40 to 0.82). Overall ICU stay was shorter in group R; time to discharge to the ward was shorter in group R as well (log-rank P = 0.01, HR = 0.63 (0.44 to 0.90)). ICU and hospital mortality as well as overall hospital stay were comparable in both groups.

**Conclusions** Introduction of a remifentanil-based analgo-sedation protocol significantly decreased duration of ventilation and ICU stay, most probably due to its short half-time, the easy titration of sedation and the absence of prolonged oversedation in critically ill patients.

**Methformin increases skeletal muscle lactate production in pigs: a microdialysis study**

A Pignatti, P Properzi, S Magnoni, A Santini, T Langer, S Guenzani, P Bertoli, N Stocchetti, L Gattinoni

1 Università degli Studi di Milano, Milan, Italy; 2 Fondazione IRCCS Ca’ Granda, A Protti, P Properzi, S Magnoni, A Santini, T Langer, S Guenzani, A micr

Results

Ten subjects exhibited the wildtype, 20 were heterozygous and five were homozygous carriers of the allele. Peak effects of miosis did not differ for the three variants (Figure 1). However, while the results for heat pain response indicate almost no effect at all for wildtype subjects, carriers of the T allele experience a higher peak and an extended analgesia (Figure 2). Neither the parent drug nor the 3-glucuronide and 6-glucuronide serum concentrations differed significantly among the research subjects.

Conclusions

While morphine effects might be influenced in part by UGT2B7 genotype, there is a differential effect on pupil contractility and heat pain response. This cannot be readily explained by drug or metabolite serum concentration and warrants further investigation, including different enzyme product effects on cerebral morphine levels.

Eff ects of N-acetylcysteine on the erythrocyte and liver cholinesterase, nitric oxide and malondialdehyde levels in acute organophosphate toxicity
A Bayr1, H Kara1, O Köylü2, R Kocabas3, A Ak1
1Selçuk University, Selçuklu Faculty of Medicine, Konya, Turkey; 2Konya State Hospital, Konya, Turkey; 3Meram Faculty of Medicine, Konya, Turkey

Introduction The aim of this study was to investigate the eff ects of N-acetylcysteine (NAC) on the levels of erythrocyte and liver cholinesterase (CE), nitric oxide (NO) and malondialdehyde (MDA) in acute organophosphate poisoning (AOP) and to compare with pralidoxime (PAM)–atropine treatment.

Methods Twenty rabbits were divided into sham (n = 8), PAM–atropine (n = 6), and NAC groups (n = 6). The basal blood samples were taken from each test subject to measure plasma and erythrocyte CE, NO, and MDA values before toxicity. All of the groups were given 50 mg/kg DDVP orogastrically. The rabbits in the sham group did not receive treatment. The test subjects in the PAM–atropine group were given 0.05 mg/kg atropine with repeated doses when required and 30 mg/kg/i.v. bolus, then 15 mg/kg PAM i.v. every 4 hours. The subjects in the CoQ10 group received 50 mg CoQ10 i.v. Thoracotomy was performed in the 24th hour on the subjects in all groups and heart tissue samples were obtained to evaluate CE, NO and MDA values in the tissues. The test subjects were given high-dose i.v. anesthesia and were sacrificed at the end of the study.

Results In the 12th and 24th hours erythrocyte CE levels of the CoQ10 group were considerably higher than the PAM–atropine group (P = 0.007, 0.017, respectively). It was established that erythrocyte MDA and NO levels of the CoQ10 group were signifi cantly lower than the PAM–atropine group in the 12th and 24th hours (P < 0.05). Heart tissue CE levels of the CoQ10 group were considerably higher than the sham and PAM–atropine groups (P = 0.001, 0.004, 0.001, 0.000, respectively). Heart tissue MDA and NO levels of the CoQ10 group were signifi cantly lower than the sham and PAM–atropine groups (P = 0.000, 0.000, 0.001, 0.000, respectively).

Conclusions Treatment of AOP with CoQ10 plus PAM–atropine has a therapeutic eff ect on both erythrocyte and heart tissue lipid peroxidation and CE activity. Using CoQ10 with PAM–atropine in AOP patients with cardiac damage could reduce morbidity and mortality. Further clinical studies would be of benefi t to clarify this matter.
no signs of heart failure. Urine production was 200 ml/hour without any diuretic therapy, and remained high during 2 days after surgery. Laboratory investigation showed increased ANP levels during the patient’s stay. Sodium was 129 mmol/l and decreased to 127 mmol/l, GFR > 60 ml/minute, serum osmolality was 262 mOsmol/kg. Natriuresis was 175 mmol/l, urine osmolality was 563 mOsmol/kg. Pathological examination showed a large myxoma, connected to the fossa ovalis (4.3 x 4.5 x 3 cm). On the third day her urine production decreased to 70 ml/hour. Hyponatraemia persisted and 10 days later her sodium level normalised.

Conclusions We propose a mechanism of hyponatraemia caused by overproduction of physiologically active natriuretic peptides by atrial stretch and ventricular stretch caused by a large intracardial tumour. Atrial stretch releases ANP and ventricular stretch releases BNP from myocardial cells. Normally increased intracardial stretch implies a volume expansion, and release of natriuretic peptides act to regulate blood pressure by increasing sodium and water excretion. A large intracardial tumour attached to the embryonic remnant of the fossa ovalis caused intracardial stretch, mimicking a hypervolemic state. Overproduction of natriuretic peptides is seen in different clinical aetiologies such as intracerebral haemorrhage, lung cancer and pneumonia, linking natriuretic peptides to cerebral salt wasting and SIADH. We provide evidence of a rare cause of hyponatraemia and polyuria caused by overproduction of the physiological natriuretic peptide system by a large myxoma.

Hyponatremia of prognostic value in acute exacerbation of COPD
N Makhoul1, R Farah1, L Jacobson1
1Western Galilee Hospital, Naharya, Israel; 2Ziv Hospital, Zfat, Israel; 3Naharia Hospital, Naharia, Israel

Introduction Phosphorus is the most important anion and it is important to cell function, necessary to create the ATP energy, and an essential component of nucleic acids. Low levels of phosphorus in the blood may be due to a change in functioning of organs participating in the phosphorus balance and affecting the performance of different systems. A low level of phosphorus in the blood increases the exacerbation and the severity of COPD, increasing the need for mechanical ventilation.

Methods All patients were hospitalized in our hospital due to acute COPD exacerbation during 6 months. Comparison was made between the group with normal blood phosphorus and the group with a low phosphorus level. We checked the length of hospital stay, the need for ventilation, ventilation duration, mortality and morbidity rates.

Results We examined 242 patients, 73% men 27% women, average age 66.6 years. One hundred and ninety-four patients (80%) were hospitalized in the internal medicine department and 48 (20%) needed mechanical ventilation in the ICU. On admission, 95% of patients had a normal phosphorus level, 5% had a low phosphorus level, in 3.3% the phosphorus level was low, and 1.7% had a very low level of phosphorus. In the group of 48 ventilated patients, in 10% we observed a mild to moderate low phosphorus value and in 8% of patients a very low phosphorus level. See Figure 1.

Conclusions Low blood phosphorus levels contribute to increased severity of COPD and the need for ventilation, significantly increase the duration of hospital stay in the ICU, and increase mortality. Correction of these disorders may increase the survival rate of patients with COPD and may improve prognosis.

Investigation and management of hypocalcaemia amongst critically ill patients
A Carins1, M Mogk2, ID Welters1
1Royal Liverpool University Hospital, Liverpool, UK; 2Moredata GmbH, Giessen, Germany

Introduction There is a growing body of evidence linking the presence of hypocalcaemia with greater morbidity and mortality in the critically ill [1]. At present, no national guidelines for the treatment of hypocalcaemia in critically ill patients exist. The purpose of this investigation was to determine the prevalence of hypocalcaemia on admission to critical care, to assess the current diagnosis and treatment regime and to attempt to identify any correlation between severity of illness and the prevalence of hypocalcaemia.

Methods Data were collected for all patients admitted to a 13-bed ICU of a tertiary referral centre in September 2010 for at least three consecutive days of their stay. Three patients were subsequently excluded, as their data were incomplete. Serum and ionized calcium levels were reviewed for the presence of hypocalcaemia on admission and evidence of improvement over time. Sepsis was assessed according to the ACCP/SCCM Consensus definitions and APACHE II scores were calculated. Calcium levels were compared using the Wilcoxon test.

Results Fifty-three patients, 62% men and 38% women, were included. Ionized calcium levels on admission showed 75.0% of patients to be hypocalcaemic, while serum calcium levels revealed hypocalcaemia in only 72.6%. Supplementation of calcium gluconate based on daily serum calcium levels was found to be an effective treatment for hypocalcaemia and led to a significant increase in both ionized and serum calcium concentrations on day 3 (P = 0.001 and 0.020). On the third day of their stay on the ICU, 43.1% and 34.7% of patients still had low ionized and serum calcium levels. Serum calcium levels generally mirrored ionized calcium levels; however, compared with ionized calcium levels, hypocalcaemia remained undetected in two out of 53 patients (3.8%). There was no correlation between the severity of disease and the occurrence of hypocalcaemia. Similarly, a diagnosis of sepsis, severe sepsis and septic shock was not associated with hypocalcaemia.

Conclusions Serum calcium levels tend to underestimate hypocalcaemia compared with ionized calcium. Although the existing treatment strategy was found to be effective in general, the use of ionized calcium levels for detection and treatment of hypocalcaemia might be more effective [2].

Seasonal vitamin D variability and its effects on the innate immune response during human endotoxemia
MJ Van den Berg1, M Kox1, A Van der Ven1, JP Wielders2, P Pickkers1
1Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands; 2Meander Medical Centre, Amersfoort, the Netherlands

Introduction In the past several years, an important immunomodulatory role for vitamin D has been identified. At high latitudes,
seasonal vitamin D deficiency is common due to low UV-B radiation exposure, which is necessary for the synthesis of vitamin D. In this retrospective study we investigated whether vitamin D levels are subject to seasonal variation and whether plasma levels of vitamin D correlate with the extent of the innate immune response during human endotoxemia.

**Methods** Plasma levels of 25-hydroxyvitamin D3 were determined in samples obtained just prior to administration of an intravenous bolus of 2 ng/kg endotoxin (lipopolysaccharide derived from Escherichia coli O113) in 114 healthy male young volunteers. Plasma levels of the inflammatory cytokines TNFα, IL-6, IL-1β and IL-10 were determined serially after endotoxin administration. Correlation analysis was performed to investigate the relationship between vitamin D status and inflammatory cytokine levels.

**Results** Vitamin D levels were not subject to seasonal variation in the studied population. Furthermore, vitamin D levels did not correlate with peak cytokine levels or areas under the curve of cytokine time courses. Finally, vitamin-D-deficient subjects (<40 nmol/l) displayed an identical innate immune response compared with vitamin-D-sufficient subjects.

**Conclusions** Vitamin D levels in young healthy males appear to be stable throughout the year. Plasma levels do not correlate with the extent of the innate immune response during human endotoxemia. These findings question the role of vitamin D in modulation of the innate immune response.

**High bone turnover in critically vitamin-D-deficient patients**

K Amrein, H Sourj, A Holl, C Schneid, TR Pieber, H Dabnig

Medical University of Graz, Austria

**Introduction** Vitamin D deficiency, hypocalcemia and acute immobilization negatively affect bone metabolism and are present in the majority of critically ill patients. Although high bone turnover is highly prevalent in the ICU and might compromise long-term outcome, there are currently no data on fracture risk after critical illness.

**Methods** We assessed bone turnover comparing placebo (P) with a cholecalciferol loading dose (VITD) over a 1-week observation period in critically ill medical patients with vitamin D deficiency (25(OH)D ≤20 ng/ml). Markers of bone and mineral metabolism (β-CTx, OC, osteocalcin, IL-6, IL-1βA and IL-10) were determined serially after endotoxin administration. Correlation analysis was performed to investigate the relationship between vitamin D status and inflammatory cytokine levels.

**Results** Vitamin D levels were not subject to seasonal variation in the studied population. Furthermore, vitamin D levels did not correlate with peak cytokine levels or areas under the curve of cytokine time courses. Finally, vitamin-D-deficient subjects (<40 nmol/l) displayed an identical innate immune response compared with vitamin-D-sufficient subjects.

**Conclusions** Vitamin D levels in young healthy males appear to be stable throughout the year. Plasma levels do not correlate with the extent of the innate immune response during human endotoxemia. These findings question the role of vitamin D in modulation of the innate immune response.

*P <0.05.
Survival after surgery. Before surgery Se levels were low (75.8 ± 8.7 vs. 72.8 ± 3.9). The NOx, MDA and SOD levels were elevated (respectively 35.1 ± 1.2 vs. 35.2 ± 1.8; 6.4 ± 0.4 vs. 6.6 ± 0.38; 106 ± 8.7 vs. 107 ± 8.8). After Se supplementation, Se levels were significantly higher in G2 compared with G1 (90.8 ± 7.42 vs. 75.7 ± 9.91, P < 0.05). On the fifth day the NOx, MDA and SOD levels decreased in G2 compared with G1 (respectively 29.5 ± 1.2 vs. 39.3 ± 2.2; 6.59 ± 0.9 vs. 9.8 ± 1.2; 84 ± 10.1 vs. 123 ± 7.7, P < 0.05). In G2, postoperative encephalopathy was significantly less (P = 0.013).

Conclusions: Even in the early postoperative period, administration of high doses of sodium selenite in patients with colorectal liver metastasis who underwent extensive liver resection helps to improve AS. However, a small number of observations does not allow one to assess accurately the clinical effect of high doses of Se for these patients.

**P375** Nutritional support in severe traumatic brain injury

MN Cote, F Lauzier, V Bibeau, P Labbe, AF Turgeon
CHA-Hôpital de l’Enfant-Jésus, Université Laval, Quebec, Canada

**Introduction** Clinical guidelines recommend full caloric replacement within 7 days after severe traumatic brain injury (TBI) since it may improve clinical outcomes. However, enteral feeding is often poorly tolerated in this population. We hypothesized that most patients with severe TBI do not receive adequate caloric and protein intake.

**Methods** We performed a retrospective cohort study of randomly selected patients with severe TBI (GCS ≤8) identified with ICD-10 codes and admitted to a 24-bed ICU of a Canadian level 1 trauma center between January 2005 and December 2006. We excluded patients <16 years old, with penetrating TBI or mechanically ventilated for <48 hours. Using a standardized pretreated case report form, we collected daily kilocalories and proteins (ordered and received), sedation, use of prokinetic drugs and post-pyloric access. The primary endpoint was achievement of ≥90% of caloric and protein requirement within 7 days. Secondary endpoints were factors associated with achievement of nutritional goals and with gastric intolerance (one episode of residuals ≥250 ml/4 hours). A sample size of 100 patients was required to obtain a margin of error of 9%.

**Student t and chi-square tests were used to compare continuous data and proportions. We obtained ethics approval.**

**Results** Among the 109 patients included, 82.6% were men (mean age 40.5 ± 20.5 years, GCS 3.7 ± 1.3 and BMI 25.3 ± 5.1 kg/m²). Patients had 1,204 potential feeding days. Ninety-six patients (88.1%) were fed by day 3. Mean caloric and protein orders were 32.6 ± 4.8 kcal/kg and 1.4 ± 0.2 g/kg, respectively. Two patients never received enteral nutrition. Nutrition was started at a mean rate of 32.6 ± 9.3% of the nutrition goal using the stomach as the initial access in 97.2%. The mean caloric delivery (kcal/kg/day) was 14.8 ± 12.8. Energy delivery (kcal/kg/day) was 14.8 ± 12.8 vs. 17.1 ± 12.7* vs. 17.8 ± 12.6* <0.0001.

**P376** Energy deficit and hospital length of stay can be reduced by quality management of nutrition therapy: the ICU dietitian is essential

L. Soquet, JP Revelly, C Longchamp, MD Schaller, MM Berger
HES-SQ, Geneva, Switzerland; CHUV, Lausanne, Switzerland

**Introduction** Several studies show that nutrition delivery is insufficient, resulting in large energy deficits during the ICU stay [1]; the problem persists despite the diffusion of guidelines. The barriers to guideline implementation are known [2]. This study aimed at measuring the clinical impact of a two-step interdisciplinary quality nutrition program incorporating knowledge of the barriers.

**Methods** A prospective interventional study over three periods (A: baseline, B: intervention periods) in the mixed ICU of a university teaching hospital. Inclusion: patients requiring >72 hours of ICU. Intervention was a two-step quality program after baseline analysis: first, implementation of feeding guidelines; and second, additional presence of an ICU dietitian. Variables: anthropometry, severity scores, energy delivery and balances (daily, day 7, discharge), feeding route, length of stay, and mortality.

**Results** In total, 604 admissions and 6,073 days were analyzed. Patients in period A were less sick (lower SAPS and less rapidly fatal McCabe scores) than those of periods B and C. Energy delivery and balance increased gradually: impact was particularly marked in the cumulated energy balance on day 7 (P < 0.001). The feeding technique changed: use of EN increased from A to B (stable in C); combined and PN increased progressively. Oral intakes were uniformly low (305 kcal/day). Hospital mortality paralleled severity in periods B and C. The hospital stay was shorter in period C (P = 0.048). See Table 1.

**Conclusions** A bottom-up protocol improved nutritional support. The ICU dietitian further improved the process (early introduction, feeding route), achieving better early energy balance.

**P377** Enteral feed absorption during therapeutic hypothermia following out-of-hospital cardiac arrest

C Smith, J Nolan, M Williams
Royal United Hospital, Bath, UK

**Introduction** Enteral feeding is the preferred nutrition method in critically ill patients, with early administration leading to improved outcome [1]. There are no studies documenting the feasibility of enteral feeding during therapeutic hypothermia following cardiac arrest and, in our experience, many intensive care clinicians withhold enteral feed during the hypothermic period.

**Methods** Data were collected retrospectively from patients admitted to the Royal United Hospital ICU for therapeutic hypothermia following out-of-hospital cardiac arrest between 2002 and 2008. We recorded the total enteral feed input, total volume of gastric aspirate, total volume of gastric aspirate that was discarded and the number of vomiting episodes for 72 hours. The first 24 hours was the period of
cooling, the second 24 hours included 14 hours of re-warming and
10 hours of normothermia, and the third 24 hours was normothermia.
Feed balance was calculated by subtracting the volume of discarded
aspirate from the volume of enteral input.

Results Thirty-two patients were included in the study. The median
feed balance, percentage of patients with a positive feed balance, number
of vomiting episodes and percentage of patients vomiting for
each day is given in Table 1.

Conclusions Absorption of enteral feed increased with increasing
core temperature. Even during hypothermia, the median feed
balance was positive by 265 ml and 78% of patients had a positive
feed balance on day 2 and 94% of patients experienced vomiting. This
implies that at a core temperature of 33°C there is sufficient gastrointestinal
function to enable some enteral feed to be absorbed in most patients
without a significant increase in vomiting. This suggests that it may
be appropriate to feed patients undergoing therapeutic hypothermia
following cardiac arrest.

Enteral nutrition in mechanically ventilated patients with cervical
spinal cord injury
S O’Connor1, Y Yau1, R Yandell1, K Lange1, J Alexander1, B Freeman1,
M Chapman1
1Royal Adelaide Hospital, Adelaide, South Australia, Australia; 2University
of Adelaide, South Australia, Australia; 3Repatriation Hospital, Adelaide,
Australia

Introduction The aim of this study was to assess the adequacy of
nutrition provision to mechanically ventilated patients in the acute
phase after cervical cord injury. High spinal cord injury is associated
with reduced gastric emptying due to excessive sympathetic activity
from the isolated thoracolumbar cord (1), which is believed to
compromise nasogastric delivery of nutrition and worsen clinical
outcomes. However, the success of feeding early after high spinal cord
injury has not been formally evaluated.

Methods A retrospective cohort study. Success of enteral feeding and
associated factors were reviewed for 28 days (or until ICU discharge) in
all patients mechanically ventilated for at least 48 hours with cervical
spinal cord injury in a mixed, level 3 ICU, over a 2-year period. Adequacy
of nutrition was defined as net calories delivered (including propofol) as
a percentage of goal calories prescribed. Energy requirements were
determined using the Schofield equation or a weight-based method
(25 kcal/actual body weight). Data are presented as median and range.

Results Seventeen patients were recruited (14 male, aged 37 years (18
to 78), BMI 27 (23 to 35), APACHE II 14 (8 to 26), ASIA score A – 13, B – 4,
ICU length of stay (LOS) 40 days (14 to 78), hospital LOS 82 days (34
to 219), of which two died. Six patients were discharged prior to day
28. Goal calories were 2,140/day (1,867 to 3,400). Patients commenced
enteral feeding 44 hours (1 to 107) after ICU admission and received a
mean 73% (SD = 19%) of nutritional goals over the 28-day study period.
Energy delivery by day 4 reached 88% of goals. There was a significant
relationship (r = 0.564; P = 0.029) between feed volume and hospital
LOS. Feeding did not influence any other clinical outcomes including
ICU LOS and mortality. Eleven (65%) patients received prokinetics
for 7 days (2 to 20). No patients received TPN or post-pyloric feeding.

Conclusions Despite a high proportion of patients requiring pro-
kinetics, most received adequate nasogastric nutrition during their
stay in the ICU. Anecdotal evidence of weight loss and wasting after
cervical spinal cord injury suggests that there are complex nutritional
requirements in this group of patients and will form the basis for
further studies.

Reference
Protein losses and nitrogen balance during continuous renal replacement therapy (CRRT) has become a popular treatment modality, but may have the disadvantage of producing substantial protein losses, reported to be as high as 1.3 g/l. In the USA and Europe, CRRT outputs reach 50 l/day, and this value would amount to protein losses of up to 65 g/day. ASPEN and ESPEN guidelines recommend that these patients should receive increased protein, up to a maximum of 2.5 g/kg/day, and that protein should not be restricted in patients with ARF as a means to avoid or delay initiation of dialysis therapy. But most previous studies were conducted in the era when energy requirements were adjusted by stress factors, and without intense glucose control therapy. So the optimal amount of protein supplementation in ARF patients in recent nutritional control is still unknown. In Japan, due to the limitation of doses of dialysate by health insurance it remains only 15 l/day, and protein losses are expected to be smaller than western countries. We measured the amount of nitrogen concentration in dialysate/ultrafiltrate samples, and calculated the nitrogen balance in such patients.

Methods We analysed eight critically ill patients requiring CRRT in the ICU in a university hospital retrospectively. Patients received NPC 25 kcal/kg/day increasing to the target over the next 2 to 3 days, preferably by enteral (postpyloric) route if possible. The dose of protein intake differed mainly due to BUN concentration (70 mg/dl was acceptable).

Results Of eight patients, six died (D) and two survived (S). Days of CRRT treatment were 11.7 ± 5.2 (4 to 20) in group D versus 9.0 ± 5.7 (5 to 13) in group S, and 24 hours creatinine clearance of CRRT was 9.6 ± 2.9 versus 10.5 ± 3.6 ml/minute/m², dialysate/ultrafiltrate nitrogen loss was 6.4 ± 3.3 versus 8.5 ± 4.1 g/day, and nitrogen balance was –0.08 ± 0.48 versus –0.034 ± 0.44 g/kg/day (~5 ± 6.6 vs. 2.6 ± 6.1g/day), retrospectively. The estimated amount of protein loss was expected to be almost 40 g/day.

Conclusions Nitrogen losses in dialysate/ultrafiltrate samples were larger than previously reported even in a smaller dialysate/ultrafiltrate dose. In ICU patients with ARF, protein requirements can differ and have to be assessed individually. Large, prospective, randomized, controlled studies are needed to optimize the dosing of protein in critically ill patients with ARF who are treated with CRRT and the effects on patient morbidity and mortality.

Lipid-enriched and protein-enriched enteral nutrition limits inflammation in a human endotoxemia model
M Kox1, T Lubbers2, JJ De Haan3, JW Greve1, JC Pompe1, BP Ramakers1, M Kox1, T Lubbers2, JJ De Haan3, JW Greve1, JC Pompe1, BP Ramakers1,
1Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands; 2Maastricht University Medical Centre, Maastricht, the Netherlands; 3Atrium Medical Center, Heerlen, the Netherlands.

Introduction
Enteral administration of lipid-enriched nutrition was previously shown to attenuate inflammation and organ damage via a cholecystokinin-mediated vagovagal reflex in animal studies. The current proof-of-principle study investigates the immunomodulatory potential of enteral lipid-enriched and protein-enriched nutrition during experimental human endotoxemia.

Methods
After an overnight fast, 18 healthy male subjects received an intravenous bolus of Escherichia coli lipopolysaccharide (LPS; 2 ng/kg). Subjects in the fasted group (n = 6) were deprived of food throughout the study, while subjects in the intervention groups were fed either enriched (n = 6) or isocaloric control nutrition (n = 6) via a nasojejunal tube, starting 1 hour prior to LPS administration until 6 hours afterwards.

Results
LPS administration resulted in a marked inflammatory response. Continuous postpyloric administration of nutrition increased plasma cholecystokinin levels. Enriched nutrition attenuated circulating levels of the proinflammatory cytokines TNFα and IL-6 and the IL-1 receptor antagonist compared with control nutrition (all: P <0.01) and fasted subjects (all: P <0.05). Additionally, enriched nutrition augmented the anti-inflammatory response, reflected by increased IL-10 release compared with fasted subjects (P <0.0001). See Figure 1.

Conclusions
The current study establishes the anti-inflammatory potential of enriched nutrition in humans. The immediate anti-inflammatory effect of enriched nutrition suggests that the beneficial effects are mediated via a cholecystokinin-dependent vagovagal reflex. Enteral administration of enriched nutrition is a promising intervention to modulate the immune response in the early course of systemic inflammation.

Inflammation causes arginine to become an essential amino acid in critically ill children
CT De Betue1, DA Van Waardenburg2, KF Joosten1, NE Deutz3
1Erasmus MC, Rotterdam, the Netherlands; 2MUMC, Maastricht, the Netherlands; 3UAMS, Little Rock, AR, USA

Introduction
In critically ill children we previously found decreased plasma levels of arginine (Arg) and its precursor citrulline (Cit), with a strong inverse relation to C-reactive protein (CRP) [1]. Cit is the sole precursor of Arg de novo synthesis in the body. We hypothesized that Arg becomes an essential amino acid, because Cit availability is reduced during inflammation. Therefore we studied Cit and Arg production, using stable isotope technology, in relation to the severity of inflammation in critically ill children.

Methods
Twenty-two critically ill children (age 0.89 ± 0.04 years) with different levels of inflammation were studied on day 3 post-admission; viral bronchiolitis (group 1, n = 9), infectious disease without shock (group 2, n = 6) and septic shock (group 3, n = 7). A 2-hour stable isotope tracer protocol was performed after at least 4 hours fasting to determine Arg and Cit kinetics. Data presented as mean ± SE. Statistics by ANOVA, Spearman’s correlation.

Results
See Figure 1 for results per group. CRP was significantly different between groups. Cit production was significantly lower in the group with highest inflammation compared with the group with lowest inflammation. Cit production was inversely correlated with plasma CRP (r = –0.58, P <0.001).

Conclusions
Our data show that with increasing rate of inflammation the production of Arg’s precursor Cit is severely depressed. Previously we found that de novo Arg production is almost equal to Cit production...
Our aim was to compare the effects of intravenous, enteral and enteral + intravenous supply of glutamine on malnutrition in sepsis.

Methods
This was a prospective, randomized, controlled, single-blind, clinical study. Forty septic patients with malnutrition were randomly divided into four groups (n = 10 each group). All patients were receiving enteral access, and had a clinical diagnosis of either severe sepsis or septic shock. All patients received enteral nutrition during 15 days. Enteral feeding was delivered at a constant rate to achieve energy expenditure (Harris–Benedict equation). Blood and urine samples were obtained for transferrin, nitrogen balance and creatine/height index at least at baseline and on study days 7 and 15. Group 1: received 30 g/day intravenous glutamine, Group 2: received 30 g/day enteral glutamine, Group 3: received 30 g/day enteral + 15 g/day intravenous glutamine, Group 4: control group, without glutamine only enteral feeding. Data were compared by the Tukey HSD test.

Results
Nitrogen balance levels were not significantly different between groups on the first 7 and 15 days. The transferrin level was higher in Group 2 than Group 4 on the first 7 days (P <0.001). Transferrin levels were not significantly different between the other groups. Transferrin levels were higher in Group 3 than Group 2 (P <0.05) and Group 4 (P <0.001) in 15 days. Creatine/height index was higher in Group 3 than Group 4 (P <0.05) in 15 days.

Conclusions
Enteral plus intravenous supplemented glutamine has beneficial effects on transferrin and creatine/height index than only enteral or intravenous supply of glutamine. Also, we observed that enteral feeding of supplemented glutamine has beneficial effects on transferrin, nitrogen balance and creatine/height index in Groups 1, 2 and 3 when compared with Group 4.

Glucose absorption following gastric and small intestinal nutrient administration in the critically ill

M Chapman, A Deane, A Di Bartolomeo, A Zaknic, M Summers, N Nguyen, L Besanko, C Burgsad, M Horowitz.
Royal Adelaide Hospital, Adelaide, Australia

Introduction Glucose absorption from the stomach is abnormal related to low gastric emptying and impaired in critically ill patients (CIP) with normal gastric emptying, suggesting that small intestinal (SI) factors may also be responsible. Small intestinal absorption of nutrient has not been formally quantified in this group. The aim was to quantify and compare glucose absorption following gastric and SI administration in CIP and healthy volunteers (HV).

Methods Data from studies where glucose absorption had been measured were analysed. Sixty-six CIP (age: 51 ± 2, APACHE II: 17 ± 1) and 50 HV (age: 43 ± 3) were administered 100 ml Ensure (liquid nutrient 1.06 kcal/ml), labelled with 3 g 3-OMG to evaluate 3 and 50 HV (age: 43 ± 3) were administered 100 ml Ensure (liquid nutrient 1.06 kcal/ml), labelled with 3 g 3-OMG to evaluate 3 g 3-OMG to evaluate glucose absorption. Nutrient was administered via nasogastric (n = 44; CIP = 24; HV = 20) or SI (n = 72; CIP = 42; HV = 30) catheters. Plasma 3-OMG concentrations were measured at intervals for 240 minutes; peak, time to peak and area under the concentration curve (AUC) were calculated. Feed-intolerant patients were defined by gastric residual volume >250 ml in the 24 hours prior to study or requiring prokinetics for pre-existing feed intolerance. Data are mean ± SEM or median (range) and were analysed using nonpaired Student’s t tests.

Results Glucose absorption was markedly reduced in patients following both intragastric (AUC 0 to 240: CIP = 49 ± 7 vs. HV: 80 ± 4 mmol/l/minute; P <0.001; peak concentration CIP: 0.32 (0.004 to 0.804) vs. HV: 0.51 (0.343 to 0.679) mmol/l; P <0.001; time to peak CIP: 140 (30 to 240) vs. HV: 74 (45 to 120) minutes; P <0.001) and SI nutrient (AUC 0 to 240: CIP: 57 ± 4 vs. HV: 72 ± 4 mmol/l/minute; P = 0.008; peak concentration CIP: 0.57 (0.01 to 0.88) vs. HV: 0.47 (0.28 to 0.88) mmol/l; P = 0.02; time to peak CIP: 87 (15 to 240) vs. HV: 54 (15 to 120) min; P = 0.01). Gastric glucose absorption was delayed when compared with SI administration in CIP (time to peak: gastric: 140 (30 to 240) vs. SI: 86 (15 to 240) minutes; P = 0.005); however, there was no difference in overall glucose absorption when comparing gastric and SI administration in both HV and CIP. Feed-intolerant patients had reduced SI glucose absorption (AUC 240: intolerant 44 (2 to 98) vs. tolerant 75 (15 to 101) mmol/l; P = 0.01).

Conclusions Glucose absorption is substantially impaired in the CIP even when delivered directly into the SI. This suggests mechanisms in the SI contribute to nutrient malabsorption. Delivery of nutrient directly into the SI (particularly in those CIP who are feed intolerant) may not result in improved nutrient absorption.

Enhanced insulin sensitivity variability in the first 3 days of ICU stay: implications for tight glycemic control

JC Chase1, AJ Le Compte1, S Penning2, KT Moorhead2, P Massion3.

Introduction Effective tight glycemic control (TGC) can improve outcomes, particularly in cardiovascular surgery, but is difficult to achieve. Variability in insulin sensitivity/resistance resulting from the level and evolution of stress response, particularly early in a patient’s stay, can lead to hyperglycaemia and variability, which are associated with mortality. This study quantifies the daily evolution of the variability in insulin sensitivity for cardiovascular surgical and all other ICU patients.

Methods Retrospective analysis of SPRINT TGC study data. Model-based insulin sensitivity (SI) was identified hourly from data. Hour-to-hour percentage changes in SI were assessed for cardiovascular surgical (CVS) patients (n = 76) and all other, noncardiovascular surgery (Non-CVS) patients (n = 317). Results are compared for days 1, 2, 3 and days 4 onward. Cumulative distribution functions (CDFs), median values, and interquartile points (25th and 75th percentiles) are used to assess differences between groups and their evolution over time.

Results CVS patients are more variable than Non-CVS patients, on days 1 to 2 (P <0.005) and similar on days 3 and 4 onward (P ≥0.13). Variability declines by day. CVS and Non-CVS patients are both more variable on each of days 1 to 3 than the overall day 4 onward values (P <0.005). At the interquartile percentiles, CVS patients are 1.4 times more variable than Non-CVS patients on day 1, 1.4 to 1.44 times on day 2, and 1 to 1.2 times on day 3, but identical (<1.1x difference) on day 4 onward. Absolute SI increases daily for both groups, and the difference between groups shrinks from 33% to 12% over days 1 to 3 and is 4% on day 4 onward (P <0.005 for all). Glycemic control was equivalent for both groups (P >0.05) and thus these results were not due to differences in TGC achieved, but patient-specific factors instead.

Conclusions All ICU patients exhibit greater insulin sensitivity variability over days 1 to 3, and cardiovascular surgery patients are more variable than others. Clinically, the results imply that TGC patients, especially cardiovascular surgical surgery patients, will require greater measurement frequency, reduced reliance on insulin, and more explicit specification of carbohydrate nutrition in days 1 to 3 to safely minimise glycaemic variability and maximise control for best outcome.

Endogenous insulin secretion and suppression during and after sepsis in critically ill patients: implications for tight glycemic control protocols

CG Pretty1, PD Docherty1, J Lin2, L Pfeifer2, U Jamaludin1, GM Shaw1, AJ Le Compte1, JC Chase1.

1University of Canterbury, Christchurch, New Zealand; 2University of Otago, Christchurch, New Zealand; 3Christchurch Hospital, Christchurch, New Zealand

Introduction Insulin infusions over 24 hours can suppress endogenous insulin secretion in healthy subjects 30 to 45% [1]. Virtually all tight glycemic control (TGC) protocols deliver insulin via infusion. This study examines the impact of bolus delivery of insulin in TGC on the endogenous insulin secretion of critically ill patients.

Methods Eighteen patients from the Christchurch Hospital ICU enrolled in a prospective clinical trial studying sepsis each had two sets of blood samples assayed for insulin and C-peptide. The first set was taken at the commencement of the SPRINT TGC protocol for patients with suspected sepsis. The second set was taken when their SIRS score was consistently below 2. Each set had four samples taken at: –1, 10, 40 and 60 minutes following bolus delivery of insulin as required by SPRINT to capture endogenous insulin secretion during the bolus profile. Bolus size was dictated by the protocol, but was in the range 2 to 6 units. Model-based methods [2] were used to calculate the endogenous insulin secretion rate for each set of samples. The level of suppression was calculated as the ratio of the secretion rate between 5 and 15 minutes (just after peak plasma insulin) and average of the 0 to 5 minutes (basal) and 15 to 60 minutes (return to basal) secretion rates identified.

Results Median (IQR) endogenous insulin secretion rates for the first and second set of samples, respectively, were 4.0 (1.4 to 5.4) U/hour and 1.5 (1.0 to 3.3) U/hour, indicating a significant drop in secretion, post-sepsis and later in stay (P <0.05). Median (IQR) level of suppression for the first set of samples of each patient was 1.08 (0.96 to 1.29), showing an increase in secretion for most patients during suspected sepsis. Second set suppression post-sepsis was 1.02 (0.83 to 1.12), indicating limited or no suppression outside C-peptide assay error of 9%. Analyses of blood glucose levels, culture-confirmed sepsis and diabetic status show no consistent trends.

Conclusions TGC can be beneficial, but carries a high risk of hypoglycaemia. Bolus insulin may provide more effective TGC as unsuppressed endogenous insulin supplements the exogenous dose, possibly lowering the required doses and the risk of hypoglycaemia. These results suggest a comparative study between bolus and infused insulin in TGC.

Effects of hyperglycemia and intensive insulin therapy on neurons and glial cells during critical illness  
1KU Leuven, Belgium; 2 ‘Lambézsaïre Université Hospital, Paris, France; 3 Pasteur Institute, Paris, France; 4 Raymond Poincare University Hospital, Garches, France  

**Introduction**  
Treating hyperglycemia with intensive insulin therapy (IIT) may improve outcome of critically ill patients. However, this benefit may be counteracted by the increased risk of hypoglycemic episodes with this intervention, which may cause brain damage. We determined the effects of hyperglycemia and IIT on neurons and glial cells during critical illness.

**Methods**  
We performed a postmortem examination of the hippocampus and frontal cortex of 10 critically ill patients who were randomized to conventional insulin therapy (CIT, n = 5) or IIT (n = 5) in two previous studies [1,2]. Glucose levels differed between CIT (9.3 (8.5 to 11.2) mmol/l) and IIT (6.1 (5.3 to 6.2) mmol/l) patients (P < 0.01). Neuronal damage and density and function of glial cells were assessed by histochemistry and western blot. Data were compared with eight age-matched controls who died suddenly from extracranial injury.

Mechanisms were explored in a validated burn injury model of prolonged critical illness. Critically ill rabbits were allocated to four groups, each a combination of normal or elevated blood glucose with normal or elevated insulin levels. Brain samples were collected after 7 days of illness. Healthy rabbits were included as controls.

**Results**  
In the hippocampus of CIT patients, neuronal damage (P = 0.002) and microglia activation (P = 0.003) were increased as compared with controls. Density (P = 0.02) and activation status (P = 0.03) of astrocytes were decreased. IIT did not affect neuronal damage, but reduced microglia activation (P = 0.03) and restored astrocyte function and density (P = 0.009) versus CIT. Findings in the frontal cortex were largely similar. The experimental model showed pronounced neuronal damage and microglia activation with hyperglycemia, which were restored to normal levels with normoglycemia. Astrocytes were activated only in rabbits with high insulin and normal glucose levels, without increased network formation, as assessed by connexin-43 levels. MnSOD protein expression levels suggested reduced oxidative stress by glycemic control under high insulin levels.

**Conclusions**  
Critical illness is characterized by increased neuronal damage and microglia activation in the hippocampus and frontal cortex under hyperglycemia. Our data suggest that maintaining normoglycemia with IIT reduces brain inflammation and may be neuroprotective, despite the risk of brief episodes of severe hypoglycemia.

Errors in preparation of insulin infusions for critically ill patients  
R Pierson, I Mackenzie  
Queen Elizabeth Hospital, Birmingham, UK  

**Introduction**  
Dysglycaemia is associated with poorer outcomes in critically ill patients. Maintenance of normoglycaemia by the administration of intravenous insulin is an important therapy in the ICU, but many factors can affect plasma glucose levels in often unpredictable ways. Even if insulin could be delivered to patients at a guaranteed rate, the process of controlling glucose levels with exogenous insulin infusions is not straightforward. The preparation and administration of any drug for infusion is potentially subject to error. Insulin infusions are of particular concern, since they must be diluted from a concentrated stock solution. Random errors in the preparation of insulin infusions could result in significant differences between the concentration of insulin prescribed and that seen in the infusion. This would affect the rate of insulin delivery and could potentially result in unstable plasma glucose levels.

**Methods**  
Samples of 22 insulin infusions were taken over a 2-week period on a 14-bed adult general ICU. Each infusion had been prescribed as 1 IU/ml. After 10,000-fold dilution, samples were assayed using a two-step time-resolved fluorometric assay. To quantify the intra-assay variability, multiple aliquots were taken from a single sample of insulin. These were diluted and assayed in the same way as the ICU samples. Statistical analysis was performed via the SPSS computer package.

**Results**  
The 22 insulin solutions had a mean concentration of 0.99 IU/ml (SD 0.10, 95% CI: 0.95 to 1.03 IU/ml). The coefficient of variation was 10% (95% CI: 7.8 to 14.0%), with the insulin concentration ranging from 0.84 IU/ml to 1.16 IU/ml. Intra-assay coefficient of variation was found to be 3.6% (95% CI: 2.4 to 6.8%).

**Conclusions**  
The concentration of the insulin solutions studied varied from the prescribed concentration by up to 16%. This is probably due to random errors arising from differences in the methods of preparations of infusions by different nursing staff in the ICU. Insulin solutions could be prepared more accurately in a central location (for example, pharmacy), taking advantage of standardised techniques and equipment. This may reduce some of the random errors we have demonstrated and could potentially improve glycaemic control.

**P392**  
Blood glucose variability, measured as mean absolute glucose, strongly depends on the frequency of blood glucose level measurements  
RE Harmsen, F Van Braam Houckegeest, PE Spronk, MJ Schultz, A Abu-Hanna  
1 Academic Medical Center, Amsterdam, the Netherlands; 2 Erasmo Hospitals, Hilversum, the Netherlands; 3 Gelre Hospitals, Apeldoorn, the Netherlands  

**Introduction**  
Blood glucose variability (BGV) has been associated with outcome of critically ill patients [1-3]. Different BGV metrics exist, including mean absolute glucose (MAG) [4], which is the mean of absolute change per hour in glucose level. We hypothesized MAG to depend on the blood glucose level (BGL) measurement frequency, as doing more measurements could lead to more changes in the insulin infusion rate and hence in changes in the follow-up BGL.

**Methods**  
We developed and implemented an evidence-based guideline for intensive insulin therapy on a mixed medical–surgical ICU in the Netherlands. The new guideline explicitly specifies when the follow-up BGL measurements should be taken, and hence influences BGL measurement frequency. We collected all BGL measurements, patient demographics and outcome information for 1 year before and 1 year after the guideline’s implementation, and analyzed the association of MAG and mortality.

**Results**  
Data for 758 and 601 patients were collected 1 year before and 1 year after implementation. The two cohorts had similar baseline characteristics: median age 71 (59 to 80) years, median APACHE II scores 17 (13 to 23). Hospital mortality did not change (30.7% and 31.6%, P = 0.729). After implementation, median BGL decreased from 117 (97 to 144) to 106 (90 to 130) mg/dl (P < 0.001), and the median BGL measurement frequency doubled, from 4 (3 to 6) to 8 (4 to 11) per day per patient (P < 0.001). MAG increased from 4.5 (2.5 to 7.0) to 6.6 (3.6 to 9.7) mg/dl/hour (P < 0.001). Both BGL measurement frequency and the APACHE II score significantly correlated with the MAG (Pearson’s correlation coefficient 0.574 and 0.19, respectively). The MAG was not independently associated with mortality when adjusting for both measurement frequency and the APACHE II score (odds ratio 1.01 (0.98 to 1.05), P = 0.42).

**Conclusions**  
The association between MAG and BGL measurement frequency and severity of illness requires careful interpretation when comparing cohorts differing in BGL measurement frequencies. It also requires adjustment for these variables when investigating the association between MAG and mortality, as it did not emerge as an independent predictor in our cohort.

P393 Validation of a virtual patient and virtual trials method for accurate prediction of tight glycemic control protocol performance 
F Suhaimi1, A Le Compte2, S Penning3, CG Prentie4, JC Pieters5, CM Shaw5, T Desaive1, JG Chase6
1University of Canterbury, Christchurch, New Zealand; 2University of Liege, Belgium; 3Erasme University Hospital, Brussels, Belgium; 4Chu Hoita, Liege, Belgium; 5Gelre Hospitals, Apeldoorn, The Netherlands; 6Gelre Hospitals, Hoita, Belgium

Introduction Effective tight glycemic control (TGC) can improve outcomes, but is difficult to achieve. In-silico virtual patient and trials offer significant advantages in cost, time and safety for designing effective TGC protocols. However, no such method has been fully validated. This study tests two matched cohorts from the Glucontrol trial treated with different protocols. The goal is to validate the ability of in-silico virtual patient models and methods to accurately predict patient-specific and clinical trial glycemic outcomes.

Methods The analysis uses records for a 211-patient subset of the Glucontrol trial (Liege, Belgium). Glucontrol-A (n = 142) targeted 4.4 to 6.1 mmol/l and Glucontrol-B (n = 69) targeted 7.8 to 10.0 mmol/l. Cohorts were matched by APACHE II score, age and sex (P > 0.3). The Glucontrol A cohort was slightly older (P = 0.04). Virtual patients are created by fitting a clinically validated model to the data, yielding time-varying insulin sensitivity profiles (Sit) that create in-silico virtual patients. Model fit and intra-patient (forward) prediction are used to validate individual in-silico virtual patients. Self-validation (tests A protocol on Group A virtual patients; and B protocol on B virtual patients) and cross-validation (tests A protocol on Group B virtual patients; and B protocol on A virtual patients) assess ability to predict a clinical trial result.

Results Model fit errors were small (<0.25%) for Group A, Group B and the entire cohort (A + B), indicating model fitness. Median prediction errors were 4.3, 2.8 and 3.5% for Group A, Group B and (A + B), indicating individual virtual patients were accurate representations of real patients. Self-validation and cross-validation results were within 1 to 10% of the clinical data for both Group A and Group B. Self-validation indicated clinically insignificant model and compliance errors. Cross-validation clearly showed that the virtual patients enabled by identified patient-specific Sit profiles can accurately predict the performance of TGC protocols different from those used to create the virtual patients.

Conclusions This study validates these virtual patients and in-silico virtual trial methods, and clearly shows they can accurately simulate, in advance, the clinical results of a TGC protocol, enabling rapid virtual trial methods, and clearly shows they can accurately simulate, predict and validate individual in-silico virtual patients.

P394 Intensive insulin therapy-associated costs differ substantially between ICUs

1Academic Medical Center, Amsterdam, the Netherlands; 2Tergooi Hospitals, Hilversum, the Netherlands; 3Medical Center Haaglanden, The Hague, the Netherlands; 4Gelre Hospitals, Apeldoorn, the Netherlands

Introduction Intensive insulin therapy (IIT) has been shown to reduce morbidity and mortality of critically ill patients [1,2]. A survey among ICU managers and nurse clinicians showed that <10% of participants evaluated costs surrounding the implementation of IIT [3]. We hypothesized IIT-associated costs to differ substantially between ICUs.

Methods Three ICUs developed and implemented an evidence-based guideline for IIT. For 1 year before and 1 year after implementation, all disposables and devices explicitly used for IIT were identified in each hospital. Local costs were calculated, based on costs for disposables and devices. Variable cost included costs associated with disposables. Fixed cost included costs associated with syringe pumps and point-of-care devices for blood glucose level (BGL) measurements.

Results A total of 2,490 patients were subjected to IIT. Patient demographics did not differ among the three ICUs and did not change over time. Median BGL declined from 119 (99 to 150) to 105 (85 to 130) mg/dl (P < 0.001). The number of BGL measurements per patient per day doubled from 4 (3 to 7) to 9 (5 to 12) per day (P < 0.001). Yearly variable costs increased from €58,574 to €118,624 (P < 0.001), yearly fixed costs increased from €450 to €14,282 (P < 0.001). Importantly, costs differed substantially from one centre to another: variable costs per patient increased from €34 (€13 to 75) to €116 (€61 to 212) (P < 0.001), from €13 (€5 to 44) to €48 (€32 to 88) (P < 0.001) and from €15 (€7 to 34) to €31 (€15 to 70) (P < 0.001) for the three ICUs, respectively. Fixed costs per bed per year increased from €9 to €250 (P < 0.001), from €13 to €384 (P < 0.001) and from €25 to €544 (P < 0.001) for the three ICUs, respectively.

Conclusions Glucose control-associated costs rise with the implementation of IIT. Major differences in costs are noticed when comparing ICUs with similar patient cohorts and similar blood glucose control metrics after implementation of IIT.

P395 Tight glycemic control managed by ICU nurses induces extremely low rates of hypoglycemia
F Delodder, C Joseph, P Maravic, T Szostek, MD Schaller, M Berger, JP Revelly, PJ Eggermann
CHUV, Lausanne, Switzerland

Introduction Recent studies failed to confirm survival benefit of tight glycemic control (TGC). Moreover, they reported high rates (6 to 18%) of hypoglycemia (<2.5 mmol/l) associated with significant mortality. The protocols used for TGC may be difficult to apply. The reasons for blood glucose level variations are complex and TGC requires in-depth individualized knowledge of the patient condition. Frequent blood glucose measurements are mandatory for continue adaptations of insulin and glucose administration. We report the evolution of blood glucose level through various phases of TGC implementation, which become progressively completely nurse driven.

Methods An internal audit performed in 2002, in five of our 32 adult ICU beds, showed 26% of hypoglycemia (>10 mmol). TGC was introduced in 2003 for all patients in the ICU and supported by detailed guidelines for bedside glucose control. TGC was progressively transferred from physicians to nurses since 2007. Nurses are specifically trained to adapt infusion rates of glucose (nutrition), insulin according to medically predefined targets (4.5 to 6.0, 6.0 to 8.0, >10 mmol/l). Arterial and venous glucose levels are determined by the central laboratory or by blood gas analyzers in the ICU. Glycemia (n = 750,178) was extracted from our electronic clinical information system (Metavision®) and analyzed with STATA.

Results Suppression of the lowest target (4.5 to 6.0 mmol/l) in May 2009 may explain the mean increase in 2009. Improved TGC is confirmed by a continuous decrease in yearly standard deviations (IQD). The proportion of hyperglycemia decreases to less than 10% in 2008, with rates of hypoglycemia (<2.5 mmol/l) 50-fold to 100-fold lower than those reported in the literature. See Figure 1.

Figure 1 (abstract P395).
Conclusions Implementation and progressive transfer of tight glucose control to ICU nurses in a large mixed adult ICU significantly decreased the proportion of hyperglycemia to less than 10%, and maintained extremely low rates of hypoglycemia (<0.1%).

P396 Investigation of the blood glucose target for mortality reduction by the proportion of hyperglycemia to less than 10%, and maintained control to ICU nurses in a large mixed adult ICU significantly decreased.

Conclusions Even a single episode of mild hypoglycemia was associated with a significantly increased risk of mortality in heterogeneous cohorts of critically ill patients, independently of severity of illness, diabetic status, diagnostic category and glycemic variability.

Introduction The blood glucose (BG) target has not been determined especially in acutely ill patients. The purpose was to investigate the BG target in order to reduce the mortality in terms of clinical phases (Early (E) phase and Late (L) phase) as well as to clarify mutual relationships among the BG parameters.

Methods Patients with daily mean BG (BGm) below 200 mg/dl in whom BG was controlled by a bedside-type artificial pancreas (AP), STG22, were researched in the E phase (3.3 ± 2.5 days after admission, n = 67) and L phase (10.1 ± 3.4 days after admission, n = 77). Nutritional support for all patients was performed by total parenteral nutrition. Studied items: BG parameters (mg/dl), BGm, daily standard deviation of BG (BGsd), daily maximal and minimal BG (BGmax, BGmin), and daily BG difference (BGd: BGmax – BGmin), maximal value of the accuracy (%) of the BG parameters for predicting survival (AS), and correlation coefficients (r) among the BG parameters.

Results AS (%): E phase/L phase; BGm below 196 (75%)/BGm below 175 (68%), BGsd below 17 (73%)/BGsd below 20 (62%), BGmax below 225 (72%)/BGmax below 218 (65%), BGmin below 172 (72%)/BGmin below 158 (73%), and BGd below 80 (70%)/BGd below 98 (68%). Strong positive correlation (r) was found in both phases (E phase/L phase) between BGsd and BGd (r = 0.87/r = 0.95), BGsd and BGmax (r = 0.79/r = 0.78), and BGd and BGmax (r = 0.77/r = 0.82). There was no significant correlation in both phases (E phase/L phase) between BGm and BGsd (r = 0.16/r = 0.37), BGm and BGd (r = 0.13/r = 0.38), and BGmax and BGmin (r = 0.07/r = 0.29).

Conclusions The above-mentioned values of the BG parameters were considered to be the BG targets. Strict BG control in the E phase is significant, from the data indicating that the AS values in the E phase were greater than those in the L phase except BGmin. BGm, BG variability (BGsd, BGd), and BGmin were suggested to be independent BG parameters. AP was essential for determining the BG target.

P397 Mild hypoglycemia is independently associated with increased mortality in the critically ill

Introduction Severe hypoglycemia (blood glucose level (BGL) <40 mg/dl) is independently associated with an increased risk of mortality in critically ill patients. The impact of milder hypoglycemia (BGL <70 mg/dl) on outcome is less clear.

Methods Prospectively collected data from two observational cohorts in the USA and in the Netherlands and from the prospective GLUCONTROL trial were analyzed. Hospital mortality was the primary endpoint.

Results We analyzed data from 3,262 patients admitted to Stamford Hospital (ST), 2,063 patients admitted to three institutions in the Netherlands (NL; loose glycemic protocol (L, n = 1,098) and strict glycemic protocol (S, n = 965)) and 914 patients who participated in the GLUCONTROL trial (GL); control arm (C, n = 460) and intensive insulin therapy arm (IIT, n = 454). The percentage of patients with hypoglycemia varied widely among the different cohorts. Patients with hypoglycemia experienced higher mortality than those without hypoglycemia within each subgroup (P <0.0001 for all comparisons), even after stratification by severity of illness or diabetic status. Multivariable logistic regression analysis revealed that hypoglycemia had a greater impact on the mortality of surgical patients than of medical patients. The impact of hypoglycemia on mortality occurred independently of mean glucose level during ICU stay or glycemic variability.

Conclusions Mild hypoglycemia is independently associated with increased risk of ICU-acquired infection

Introduction Infections that develop after admission to the ICU cause substantial morbidity and increases in resource utilization. The purpose of this investigation was to study the relationship of hypoglycemia, defined as blood glucose level (BGL) <70 or >139 mg/dl and the risk of developing ICU-acquired infection, occurring more than 2 days after ICU admission.

Methods This is a retrospective evaluation of prospectively collected data from the ICU’s clinical database. Infection control nurses using standard definitions prospectively identified ICU-acquired infections.

Results A total of 3,263 patients were admitted to a medical–surgical ICU between 1 December 2007 and 31 May 2010 and had at least three BGL measurements. In this group, 142 (4.4%) patients developed 171 infections. Patients who developed infection had significantly longer ICU length of stay (P <0.0001), higher scores for severity of illness (mean APACHE IV predicted mortality 34.8% vs. 18.5%, P <0.0001) and greater mortality (32.4% vs. 13.3%, P <0.0001) than did those who did not develop infection. Of 505 patients who did not have a single episode of malaiglycemia, none developed infection. In contrast, 16.8%, 13.1% and 7.2% of patients with lowest BGL <40, 40 to 54 and 55 to 69 mg/dl as well as 0.8%, 3.3%, 5.7% and 9.6% of patients with highest BGL 140 to 159, 160 to 179, 180 to 249 and >249 mg/dl developed infection. Multivariable logistic regression analysis identified BGL <70 and >139 mg/dl as independent predictors of the risk of developing infection (odds ratio (95% CI) 2.23 (1.45 to 3.44, P = 0.003 and 13.94 (1.91 to 101.90), P = 0.0094, respectively).

Conclusions Malaglycemia is strongly associated with increased risk of ICU-acquired infections. Efforts to decrease the rate of hypoglycemia and hyperglycemia may reduce morbidity in the ICU.

P399 Intensive insulin therapy-induced severe hypoglycemia does not affect long-term functional and cognitive outcome or health-related quality of life

Introduction Intensive insulin therapy (IIT) has been shown to reduce mortality in intensive care patients [1,2]. A large study on IIT was stopped prematurely due to high incidence of severe hypoglycemia (SH) (blood glucose level (BGL) <40 mg/dl) [3]. It remains unclear, however, whether short episodes of IIT-associated SH are truly harmful [4]. We investigated long-term quality of life and functional and cognitive outcome in patients with and without IIT-associated SH.

Methods Prospectively collected data from two observational cohorts in the USA and in the Netherlands and from the prospective GLUCONTROL trial were analyzed. Hospital mortality was the primary endpoint.

Results We analyzed data from 3,262 patients admitted to Stamford Hospital (ST), 2,063 patients admitted to three institutions in the Netherlands (NL; loose glycemic protocol (L, n = 1,098) and strict glycemic protocol (S, n = 965)) and 914 patients who participated in the GLUCONTROL trial (GL); control arm (C, n = 460) and intensive insulin therapy arm (IIT, n = 454). The percentage of patients with hypoglycemia varied widely among the different cohorts. Patients with hypoglycemia experienced higher mortality than those without hypoglycemia within each subgroup (P <0.0001 for all comparisons), even after stratification by severity of illness or diabetic status. Multivariable logistic regression analysis revealed that hypoglycemia had a greater impact on the mortality of surgical patients than of medical patients. The impact of hypoglycemia on mortality occurred independently of mean glucose level during ICU stay or glycemic variability.

Conclusions Mild hypoglycemia is independently associated with increased risk of ICU-acquired infection.

P398 Malaglycemia is strongly associated with increased risk of ICU-acquired infection

Introduction Infections that develop after admission to the ICU cause substantial morbidity and increases in resource utilization. The purpose of this investigation was to study the relationship of malaglycemia, defined as blood glucose level (BGL) <70 or >139 mg/dl and the risk of developing ICU-acquired infection, occurring more than 2 days after ICU admission.

Methods This is a retrospective evaluation of prospectively collected data from the ICU’s clinical database. Infection control nurses using standard definitions prospectively identified ICU-acquired infections.

Results A total of 3,263 patients were admitted to a medical–surgical ICU between 1 December 2007 and 31 May 2010 and had at least three BGL measurements. In this group, 142 (4.4%) patients developed 171 infections. Patients who developed infection had significantly longer ICU length of stay (P <0.0001), higher scores for severity of illness (mean APACHE IV predicted mortality 34.8% vs. 18.5%, P <0.0001) and greater mortality (32.4% vs. 13.3%, P <0.0001) than did those who did not develop infection. Of 505 patients who did not have a single episode of malaglycemia, none developed infection. In contrast, 16.8%, 13.1% and 7.2% of patients with lowest BGL <40, 40 to 54 and 55 to 69 mg/dl as well as 0.8%, 3.3%, 5.7% and 9.6% of patients with highest BGL 140 to 159, 160 to 179, 180 to 249 and >249 mg/dl developed infection. Multivariable logistic regression analysis identified BGL <70 and >139 mg/dl as independent predictors of the risk of developing infection (odds ratio (95% CI) 2.23 (1.45 to 3.44, P = 0.003 and 13.94 (1.91 to 101.90), P = 0.0094, respectively).

Conclusions Malaglycemia is strongly associated with increased risk of ICU-acquired infections. Efforts to decrease the rate of hypoglycemia and hyperglycemia may reduce morbidity in the ICU.
Methods Three hospitals developed and implemented an evidence-based guideline for IT; we collected all BGL measurements and patient demographics for the 2 years after implementation. We captured all patients with SH, and randomly selected the same number of patients without SH as controls. To evaluate long-term outcome, we used the following scores: Glasgow Outcome Scale (GOS), Short-Form (SF)-12 for health-related quality of life (HRQOL) expressed as physical (PCS-12) and mental component score (MCS-12), Informant Questionnaire on Cognitive Decline in the Elderly (IQ-CODE) and the Modified Blessed Dementia Rating Scale (MBDRS) by proxies.

Results Our analysis included 93 patients, 43 patients with at least one episode of SH, and 50 control patients. Median length of an SH episode, assuming linear changes of glucose values between measurements, was 20 (10 to 50) minutes. Patient demographics (age, gender, APACHE II scores) were similar. Median length of ICU stay was longer in patients with SH, 12 (6 to 20) versus 4 (8 to 23) days ($P <0.001$). Median BGL was lower in patients with SH, 101 (97 to 106) versus 113 (102 to 123) mg/dl ($P <0.001$). Outcome indicators were similar between patients with at least one episode of SH and control patients: GOS; 1 (1 to 1) versus 1 (1 to 2) ($P =0.173$); PCS-12; 44 (33 to 50) versus 42 (34 to 52) ($P =1.000$); MCS-12; 49 (38 to 56) versus 45 (35 to 52) ($P =0.093$), IQ-CODE; 3.0 (3.0 to 3.3) versus 3.0 (3.0 to 3.1) ($P =0.116$) and MBDRS 1; (0.5 to 1.5) versus 0.5 (0.5 to 2.5; $P =0.734$).

Conclusions Neither long-term functional and cognitive outcome, nor HRQOL of patients who encountered IT-associated SH differed from patients who never had SH. However, it should be noted that the analyzed groups are small. Our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that our data suggest ITT-associated SH not from patients who never had SH. However, it should be noted that.
MBG and who had maximum variability or highest SD. In our study cohort, 212 patients (9.6%) had hypoglycemia. In this cohort also mortality increased from 6, 10, 11, 16%, respectively, with rising SD in the same way as the whole cohort. See Figure 1.

Conclusions In summary, this study demonstrated that glucose variability is associated with ICU mortality in a large heterogeneous cohort of ICU patients. This effect was particularly strong among patients in the euglycemic range.

P403 Glycemic control in critically ill infants and children: achieved quality of control in daily clinical practice in Leuven after a RCT
E Voets, T Van Herpe, L Desmet, D Vlasselaers, P Wouters, GV Van den Berghe
UZ Leuven, Belgium

Introduction A large RCT of our research group demonstrated that targeting age-adjusted normal fasting blood glucose concentrations with insulin infusion improves outcome in critically ill infants, children and adults [1-3]. Tight glycemic control according to the Leuven guideline has been implemented as a standard of care in all Leuven ICUs. This study aims to document the quality of glycemic control in daily clinical practice in the Leuven pediatric ICU (PICU).

Methods We performed a retrospective data analysis on all pediatric patients admitted to the Leuven PICU over a 12-month period, from 1 January 2009 to 31 December 2009.

Results One hundred and forty-two of the 333 PICU admissions (43%) were infants (<1 year) and 191 of 333 (57%) were children (1 to 16 years). We obtained a total of 12,208 blood samples in the infant group. The mean blood glucose level per infant was 98 mg/dl, the median was 86 mg/dl (interquartile range 77 to 111 mg/dl). Forty-six infants (32%) experienced at least one hypoglycemic period. Hypoglycemia (<40 mg/dl) was noted in 168 (1.4%) of the samples, and 37 samples (0.3%) were extreme hypoglycemic (<30 mg/dl). A total of 8,008 blood samples were taken in the children’s group. The mean blood glucose level per child was 116 mg/dl, the median was 103 mg/dl (interquartile range 88 to 125 mg/dl). Sixteen (8%) children experienced at least one hypoglycemic period. Twenty-two samples (0.3%) were hypoglycemic (<40 mg/dl) and three samples (0.04%) were extreme hypoglycemic (<30 mg/dl).

Conclusions Even outside the setting of a RCT, the blood glucose control achieved in clinical practice mimicked that during the study on tight glycemic control in critically ill infants and children [3]. The risk of hypoglycemia was even lower than during the RCT. These outstanding results were achieved by standardized management by experienced nurses who were allowed to make anticipative decisions. The principles of managing tight glycemic control in the PICU will be shared onsite.

P404 Glycemia in blood, brain and subcutaneous tissue measured by a continuous glucose monitoring system
M Zourek, Z Jankovec, P Hykova
Faculty Hospital, Charles University, Plzen, Czech Republic

Introduction Continuous glucose monitoring system (CGMS) technology provides the opportunity to measure glycemia in different tissues [1]. The aim of our study was to determine the lag-time between blood, brain and adipose tissue during rapid glucose changes.

Methods Fifteen male hereditary hypertriglyceridemic rats underwent the experimental protocol. After intraperitoneal anesthesia, the internal jugular vein and carotid artery were catheterized. A CGMS sensor (Medtronic) was inserted into the brain by micromanipulators and to the abdominal subcutaneous tissue. At the beginning of the experiment (~120 minutes), basal glycemia was measured and calibration of the sensors was started. Thereafter, insulin infusion was started (50 mIU/kg/minute) and 20% glucose at a variable rate of infusion. Blood glucose was measured every 5 minutes with manual correction of the glucose infusion rate to maintain the glycemia level of 6 mmol/l. At a time of ~10 minutes, the calibration procedure was finished and actual glycemia was recorded to sensors. At a time of 0 minutes, a bolus of glucose 0.5g/kg was administered; and at a time of 50 minutes, a bolus of insulin 5 IU/kg was administered. Moreover glucose and insulin infusion were stopped at this time. The experiment was finished at time 130 minutes and animals were euthanized.

Results After an intravenous glucose bolus of 0.5 g/kg, glycemia rose rapidly to 14 mmol/l in 5 minutes. On the contrary, the glucose content in the brain and subcutaneous tissue was increased in a slower manner, with a maximum in about 50 minutes (brain) and 60 minutes (subcutaneous tissue). Intravenous insulin bolus of 5 U/kg was followed by lowering blood glucose concentration to a minimum of 4.5 mmol/l. The brain and subcutaneous tissue glucose content decreased slowly to a minimum of 4.2 mmol/l (brain) and 5.5 mmol/l (subcutaneous tissue). The median glucose lag-time blood versus brain and blood versus subcutaneous tissue was 10 (10; 15) minutes and 15 (15; 25) minutes, respectively ($P = 0.01$).

Conclusions Contrary to a previous study, which showed no changes in glucose dynamics after a bolus of glucose between brain, adipose tissue and muscle, our data showed that glucose in the brain follows blood excursions during acute glycemic changes more closely compared with subcutaneous tissue [2].

P405 Evaluation of a continuous blood glucose monitoring system using central venous microdialysis
F Moller, J Liska, A Franco-Cereceda
Karolinska Institute, Stockholm, Sweden

Introduction Glycemic control in critically ill patients has been shown to be beneficial. In this prospective study we therefore evaluated the accuracy and technical feasibility of a continuous glucose monitoring system using intravascular microdialysis.

Methods Fifty patients undergoing cardiac surgery were monitored using a 4F intravenous microdialysis catheter (Eirus SL®, CMA Microdialysis AB, Solna, Sweden), percutaneously placed with the tip of the catheter positioned in the superior vena cava. The catheter was connected to the Eirus monitoring system and the patients were monitored for up to 48 hours postoperatively in the ICU. As reference, arterial blood samples were taken every hour and analyzed in a blood gas analyzer (ABL800 FLEX®, Radiometer Medical, Copenhagen, Denmark).

Results Data were available from 48 patients. A total of 994 paired (arterial blood gas–microdialysis) samples were obtained. The glucose correlation coefficient ($R^2$) was 0.85. Using Clarke error grid analysis, 100% of the paired samples were in region AB and 99% in region A.
Figure 1 (abstract P406). Error grid analysis of arterial blood gas and microdialysis glucose samples.

Methods This prospective observational study included 75 consecutive ICU patients, corresponding to 302 pairs of measures (aged 56 ± 16 years, SOFA 8 ± 4, IGS2 56 ± 20). Findings from two different methods of glucose measurement were compared with laboratory blood glucose measurements: glucose meter analysis of capillary blood (fingerstick), and glucose meter analysis of arterial blood during the first 3 days in the ICU. Agreement between measurements was assessed using the Bland–Altman method.

Results The correlation coefficient between fingerstick and laboratory results was 0.91 (95% CI = 0.89 to 0.99) and 0.92 (95% CI = 0.92 to 0.94) between arterial glucose meter analysis and laboratory testing. The mean bias between fingerstick and laboratory testing was 0.16 g/l and between arterial glucose meter and laboratory testing was 0.10 g/l. Norepinephrine used did not affect the bias between methods (P = NS for all comparisons). See Figure 1.

Conclusions The agreement between methods for glucose level measurements appears not to be clinically acceptable. Either fingerstick or arterial glucose meter analysis have large limits of agreement with the gold standard laboratory testing for blood glucose measurements.

Figure 1 (abstract P405). Error grid analysis of arterial blood gas and microdialysis glucose samples.
based on a target range of 100 to 140 mg/dl. For an analyzer (YSI 2300D). Data analysis was performed to mimic a clinical and hourly reference glucose data were collected using a chemistry dl. **Methods**

A feasibility study was targeted to enroll 10 ICU patients for 72 hours in the surgical ICU of an academic institution. Enrollment was determined by two consecutive glucose values greater than 140 mg/dl. The sensor data were collected while blinded to the clinicians and hourly reference glucose data were collected using a chemistry analyzer (YSI 2300D). Data analysis was performed to mimic a clinical setting that samples glucose every 6 hours. Sensors were calibrated with four reference values per day. Paired sensor glucose values and YSI values were analyzed for sensitivity and specificity of alarm setting (100 to 140 mg/dl) based on a target range of 100 to 140 mg/dl. For sensitivity and specificity, hypoglycemia was defined as 90 mg/dl or less, and hyperglycemia was defined as 160 mg/dl or greater. This analysis was repeated for paired sensor glucose values and point-of-care meter values in the same alarm settings and target range.

**Results**

Two patients completed 72 hours at the time of this abstract. There were not enough paired points in the hypoglycemic range (<90 mg/dl) to complete an analysis (8/136). In the hyperglycemic range (101/136), the algorithm showed an average sensitivity of 91% and an average specificity of 93% against hourly reference. A high sensitivity score indicates that the new hospital CGM has few false alarms for untrue hyper events; and a high specificity score indicates that the new hospital CGM rarely misses a true hyper event.

**Conclusions**

Alarms are more than convenient features; they are an important component of product and patient safety. However, poor or inconsistent sensitivity and specificity can quickly diminish the value of an alarm, reducing it to little more than a nuisance. This analysis shows that the novel CGM has the potential to provide sensitivity and specificity to satisfy the demands of the hospital environment. Given the growing reliance on automated and semi-automated clinical systems and the inherent safety implications resulting from this trend, alarm performance should be an important consideration when evaluating these products.

**Alarm performance in a novel continuous glucose monitor**

R Gottlieb, N Yang, F Luo, C Chiu, R Joshi, S Smith

*Medtronic, Northridge, CA, USA*

**Introduction**

The ability of a continuous glucose monitor (CGM) to provide actionable information is of utmost importance in the critical care setting. Medtronic has developed a new CGM specifically for the hospital environment. A human feasibility trial was conducted to assess the performance of this system in the ICU. While often overlooked, alarm performance is essential to characterizing both the safety and value of any clinical system – especially in a critical care setting. An analysis was conducted on the sensitivity and specificity of the alarm algorithm to simulate the expected performance when used in the clinical setting.

**Methods**

A feasibility study was targeted to enroll 10 ICU patients for 72 hours in the surgical ICU of an academic institution. Enrollment was determined by two consecutive glucose values greater than 140 mg/dl. The sensor data were collected while blinded to the clinicians and hourly reference glucose data were collected using a chemistry analyzer (YSI 2300D). Data analysis was performed to mimic a clinical setting that samples glucose every 6 hours. Sensors were calibrated with four reference values per day. Paired sensor glucose values and YSI values were analyzed for sensitivity and specificity of alarm setting (100 to 140 mg/dl) based on a target range of 100 to 140 mg/dl. For sensitivity and specificity, hypoglycemia was defined as 90 mg/dl or less, and hyperglycemia was defined as 160 mg/dl or greater. This analysis was repeated for paired sensor glucose values and point-of-care meter values in the same alarm settings and target range.

**Results**

Two patients completed 72 hours at the time of this abstract. There were not enough paired points in the hypoglycemic range (<90 mg/dl) to complete an analysis (8/136). In the hyperglycemic range (101/136), the algorithm showed an average sensitivity of 91% and an average specificity of 93% against hourly reference. A high sensitivity score indicates that the new hospital CGM has few false alarms for untrue hyper events; and a high specificity score indicates that the new hospital CGM rarely misses a true hyper event.

**Conclusions**

Alarms are more than convenient features; they are an important component of product and patient safety. However, poor or inconsistent sensitivity and specificity can quickly diminish the value of an alarm, reducing it to little more than a nuisance. This analysis shows that the novel CGM has the potential to provide sensitivity and specificity to satisfy the demands of the hospital environment. Given the growing reliance on automated and semi-automated clinical systems and the inherent safety implications resulting from this trend, alarm performance should be an important consideration when evaluating these products.
Interstitial cortisol levels obtained by adipose tissue microdialysis in mechanically ventilated septic patients: correlations with total and free serum cortisol.

Critical Care 2011, Volume 15 Suppl 1

Introduction
The aim of this study was to measure cortisol in the interstitial fluid of mechanically ventilated septic patients using MD and to examine the correlation between interstitial cortisol levels and total along with free serum cortisol.

Methods
A prospective study including 31 (20 men) septic patients. All patients met the ACCP/SCCM criteria. Upon sepsis an MD catheter was inserted in the subcutaneous tissue of the upper thigh. MD sampling was done on days 1 and 2, six times/day. The collected samples were analyzed for free cortisol, glucose, pyruvate, lactate, glycerol and lactate/pyruvate ratio. Blood samples were collected for routine hematology and biochemistry on the same days. Age, gender, sepsis stage, administration of vasopressors, death in the ICU and 28-day mortality were recorded. APACHE II scores for day 1 and SOFA scores for days 1 and 2 were calculated.

Results
Seventeen patients were given norepinephrine. Albumin on day 1 was uniformly low. One-third of patients died. Cortisol values in the interstitial fluid remained constant (P = 0.480). Serum total cortisol (P = 0.116) and serum total cortisol/albumin ratio (P = 0.127) were also constant. On day 2 serum-free cortisol was higher than MD-free cortisol. Log MD cortisol correlated strongly with the log serum total cortisol and serum-free cortisol on day 2 correlated well with serum total cortisol. Day 1 log MD cortisol correlated positively with log MD pyruvate and log APACHE II. Day 2 log MD cortisol correlated positively with norepinephrine dose and log SOFA score. There were no other significant correlations of MD cortisol.

Conclusions
Adipose tissue cortisol is strongly correlated with serum total and free cortisol, suggesting that serum cortisol reflects tissue cortisol availability. The utility of MD in studying cortisol dynamics needs to be further investigated.

Early administration of hydrocortisone replacement after advent of septic shock is a major determinant of final outcome

C Katsenos1, I Tsagarakis3, A Antonopoulou1, A Savva2, A Michaloglou2, E Gramarelos-Bourboulis2, A Armaganidis1, K Mandragos1, Korgiakos2

Korgiakos University Hospital, Athens, Greece; 2 University of Athens, Medical School, Athens, Greece; 3 Attikon University Hospital, Athens, Greece

Introduction
The CORTICUS trial doubts the value of hydrocortisone replacement for final outcome of septic shock [1]. We hypothesized that the time of starting hydrocortisone may impact on the final outcome.

Methods
Retrospective analysis was made of prospectively collected data for 41 patients with septic shock (ACCP/SCCM 1992 definition) in the past year in two ICUs. Hydrocortisone was infused as suggested [2]. The time lapsing from start of vasopressors until start of hydrocortisone was determined by the patients’ charts.

Results
Early start of hydrocortisone was determined by the quartiles of lapsing time as less as 24 hours. The impact of early start is shown in Figure 1. The mean APACHE II score for patients in early start was 22.09 and for patients in late start was 18.33 (P = NS). Cox regression analysis revealed that the only factor affecting final outcome was early start of hydrocortisone (HR: 4.85, 95% CI: 1.11 to 21.22, P = 0.036) as opposed to appropriateness of antimicrobial treatment (HR: 2.80, 95% CI: 0.56 to 13.91, P = NS).

Conclusions
Despite the observational approach, early start of hydrocortisone replacement in septic shock is a critical factor for outcome.

Low preoperative total lymphocyte count as a predictor of poor outcome in adult cardiac surgery

V Lomivorotov, S Efremov, V Boboshko
Novosibirsk State Institute of Circulation Pathology, Novosibirsk, Russia

Introduction
Evaluation of operational risk is an important goal of perioperative management of patients in cardiac surgery. The aim of this study was to investigate the prognostic value of preoperative total lymphocyte count (PTLC) in peripheral blood as a predictor of postoperative complications and mortality in cardiac surgery.

Methods
A retrospective observational study of 1,380 adults who were operated on the heart using cardiopulmonary bypass (CPB) in 2009. Patient characteristics, hospital mortality, postoperative complications, ventilation time, ICU and hospital stay were analysed. Patients were divided into four groups depending on their PTLC: <1,000 cells/μl, 40 patients; 1,000 to 1,500 cells/μl, 199 patients; 1,501 to 2,000 cells/μl, 414 patients; and >2,000 cells/μl, 715 patients. Analysis was performed using univariate analysis, Kruskal–Wallace test or Fisher–Freeman–Halton exact test (for qualitative characteristics). Univariate and multivariate logistic regression analysis of in-hospital mortality also were performed. P <0.05 was considered statistically significant.

Results
PTLC <1,500 cells/μl was associated with significantly higher mortality by univariate (OR = 3.53; CI = 1.98 to 6.28; P <0.0001) and multivariate (OR = 2.06; CI = 1.02 to 4.15; P <0.044) analysis. Low
Usefulness of presepsin (sCD14-ST) measurements as a marker for the diagnosis and severity of sepsis in systemic inflammatory response syndrome

T Shozushima, Y Suzuki, T Masuda, G Takahashi, S Endo

Iwate Medical University, Morioka, Japan

Introduction CD14 is present in macrophage, monocyte, and granulocytic cells and their cell membranes, and is said to be responsible for intracellular transduction of endotoxin signals. Its soluble fraction is present in blood and is thought to be produced in association with infections. It is called the soluble CD14 subtype (sCD14-ST), and in the text below it will be referred to by its generic name, presepsin. We have previously reported that presepsin is produced in association with infection and that it is specifically expressed in sepsis. In the present study we developed a new rapid diagnostic method using a chemiluminescent enzyme immunoassay, and it made automated measurements in a shorter time possible.

Methods The subjects were 41 inpatients (25 males and 16 females), 62 ± 19 years old, who had been brought to the Critical Care and Emergency Center of Iwate Medical University, and who fulfilled at least two of the diagnostic criteria for systemic inflammatory response syndrome (SIRS) on arrival. Blood specimens were collected a total of six times – that is, on admission, and 12 and 24 hours and 3, 5, and 7 days later – and the presepsin values were measured. The sepsis markers PCT, IL-6, and CRP were also measured for comparison.

Results The results of using this method to measure presepsin values in different pathological conditions were: normal, 294.2 ± 121.4 pg/ml; local infection, 721.0 ± 611.3 pg/ml; SIRS, 333.5 ± 130.6 pg/ml; sepsis, 817.9 ± 572.7 pg/ml; and severe sepsis 1,992.9 ± 1,509.2 pg/ml. Presepsin values were significantly higher in patients with local infection, sepsis, and severe sepsis than in patients who did not have infection as a complication. In a comparative study with other diagnostic markers of sepsis based on ROC curves, the area under the curve (AUC) for presepsin was 0.845, and higher than the AUC of PCT (0.652), CRP (0.815), or IL-6 (0.672).

Conclusions In the present study we were able to obtain results similar to those obtained with the conventional ELISA method, and it was possible to diagnose sepsis more rapidly and conveniently by using the immunoassay analyzer. We are currently using the analyzer in a multicenter clinical study, and are in the process of conducting a further clinical dynamics analysis in various pathological conditions. Based on the results of the present study, it appears that presepsin will soon be widely used as a diagnostic marker of sepsis in clinical settings.

Assessment of IL-18 values in septic acute lung injury/acute respiratory distress syndrome patients

T Masuda, Y Suzuki, T Shozushima, S Endo

Iwate Medical University, Morioka, Japan

Introduction IL-18 is said to be involved in organ injury. We investigated the IL-18 values of septic acute lung injury (ALI) and acute respiratory distress syndrome (ARDS) patients.

Methods The subjects were 38 patients during the 3-year period from 2004 to 2007 from whom it was possible to collect a blood specimen within approximately 6 hours of the onset of septic ALI or ARDS. Their mean age was 67 years, and their mean APACHE II score was 29. Their SOFA score was 13, and their mean PaO2/FiO2 (P/F) ratio was 170. The P/F ratio was 246 in the ALI group and 135 in the ARDS group. There were four cases (10.5%) in the 28-day mortality group, and six cases (15.8%) in the 90-day mortality group.

Results The value of IL-18 in the died group was significantly higher than in the survived group (1,649 ± 1,056 pg/ml vs. 4,523 ± 2,798 pg/ml; P < 0.05), and in the ARDS group also significantly higher than in all patients (2,467 ± 1,880 pg/ml vs. 1,314 ± 800 pg/ml; P < 0.05).

Conclusions These results suggested that IL-18 may play a major role in progression of ARDS in respiratory disorder as multiple organ failure.
ISS scale was 35 ± 14, on a scale of APACHE II was 26 ± 6, and on the SOFA scale was 7 ± 4. We investigated the serum markers of apoptosis: sapo-1/Fas (soluble Fas receptor, sFas), sFas-L (soluble Fas ligand), Bcl-2 and pS3 (Bender MedSystems, Austria). Data are presented as mean ± standard deviation.

Results In patients with severe injury on the first day determined by the initial high level of sapo-1/Fas (410.9 ± 89.7 pg/ml), which decreased on the second day, while remaining significantly above control values, the component for sapo-1/Fas was 108 ± 12 pg/ml (P = 0.001). The level of sapo-1/Fas increased, reaching a maximum on the fifth day (419.5 ± 94.5 pg/ml). The level of sFas-L was initially almost three times higher than the reference values at 48 ± 14 pg/ml, and on the third day rose in parallel to sapo-1/Fas, reaching a maximum on the fifth day. In response to increased Fas-L, sFas is released. With increased expression of Fasl, and sFas lack of apoptosis leads to the development of multiple organ failure, and an excess of sFas massive death of lymphocytes may cause immunosuppression. The level of Bcl-2 in serum on the first day was significantly higher than in the control group (7.11 ± 5.55 ng/ml, P = 0.001) and amounted to 26.5 ± 6.3 ng/ml. On the fifth day there was a significant increase in the concentration of Bcl-2 to 39.8 ± 8.8 ng/ml, but by the seventh day the level of Bcl-2 decreased to 22.8 ± 4.3 ng/ml. Increased levels of pS3 induced by hypoxia lead to increased concentrations of Bcl-2.

Conclusions The progressive development of multiple organ dysfunction syndrome in polytrauma is associated with serum concentrations of sapo-1/Fas and sFas-L, Bcl-2, and pS3.

P418 Sulfonated immunoglobulin improves cardiopulmonary functions by promoting IGF-I production in ARDS patients with severe sepsis

Y Deguchi1, H Suga1, T Sato1, N Harada2, T Nakagawa1, K Okajima2
1Tokyo Women’s Medical University MCE, Tokyo, Japan; 2Nagoya City University Graduate School of Medical Sciences, Aichi, Japan

Critical Care 2011, Volume 15 Suppl 1

Introduction It has been emphasized that severe sepsis often leads to shock and ARDS in critically ill patients. We reported previously that sulfonated immunoglobulin (sIg) administration significantly inhibited the increase of in lung MPO activities and the increase of pulmonary vascular permeability. In the present study, we examined whether sIg improves not only ARDS but also cardiovascular dysfunction in patients with severe sepsis.

Methods ARDS patients with severe sepsis were divided into two groups, the sIg administrated group and the polyethylene glycol treated immunoglobulin (pIg) administrated group. We evaluated them by measuring the value of IGF-I, lactate, PF ratio, catecholamine index, septic severity score (SSS) and SOFA score.

Results The serum IGF-I levels in the sIg group were increased at the seventh day significantly (P < 0.05). PF ratios in the sIg group were increased significantly at the seventh day (P < 0.05). The serum lactate levels and catecholamine index in the sIg group were decreased significantly at the seventh day (P < 0.05). The total score of SSS and SOFA also significantly improved in the sIg group at the seventh day (P < 0.05).

Conclusions These observations suggest that sIg might improve cardiopulmonary functions by promoting IGF-I production in ARDS patients with severe sepsis.

P419 Fluorinated compounds mediate the immunomodulatory effects of volatile anesthetics in acute pulmonary inflammation

M Urner1, J Hermmann2, B Muller-Edenborn3, L Limbach, W Stark, B Beck-Schimmer1
1University Hospital Zurich, Switzerland; 2ETH Zurich, Switzerland

Introduction Volatile anesthetics are known as immunomodulatory substances in inflammatory as well as in ischemia/reperfusion processes [1, 2]. We investigated in a model of acute pulmonary inflammation whether these immunomodulatory effects arise from the ether basic structure or from characteristics in their halogenation.

Methods Inflammatory response in pulmonary epithelial and endothelial cells as well as in neutrophils after co-exposure to endotoxin and sevoflurane, diethyl-ether or various water-soluble molecules carrying trifluorinated carbon groups (CF3) was evaluated. Expression of monocyte chemotactic protein-1 and cytokine-induced neutrophil chemoattractant protein-1, IL-6, and IL-8 as a measure of inflammatory activity were analyzed by ELISA. Chemotactic activity of supernatants regarding neutrophil recruitment was assessed. Flow cytometric analysis of neutrophil activation was performed measuring CD11b and CD62L expression. Viability was observed using fluorescence DNA quantitation. Cytotoxicity was evaluated by measuring lactate dehydrogenase in supernatants.

Results Expression of inflammatory mediators to lipopolysaccharide stimulation in epithelial and endothelial cells was dose-dependently decreased upon exposure to sevoflurane and other molecules with CF3 groups. This was not observed for diethyl-ether or structure-similar nonfluorinated molecules. In neutrophils, chemotactic activity as well as expression of surface CD11b and CD62L was decreased by molecules carrying CF3 groups. Cytotoxicity could be excluded.

Conclusions These findings show that the immunomodulatory effects are not limited to volatile anesthetics, but are associated with a much broader class of CF3 group-containing molecules. The immunomodulatory effects could now be provided in a hydrophilic, injectable formulation for the future treatment of patients suffering from acute pulmonary inflammation in environments not suitable for volatile anesthetics.

P420 Soluble triggering receptor expressed on myeloid cells as a marker of non-infectious systemic inflammatory response syndrome

E Grigoryev, A Golovkin, V Matveeva, G Plotnikov, D Shukevich
Institute of Complex Problems of Cardiovascular Diseases, Kemerovo, Russia

Introduction The objective was to determine the diagnostic significance of soluble triggering receptor expressed on myeloid cells (sSTREM-1) as a marker of the systemic inflammatory response syndrome (SIRS) in ischemia/reperfusion (extracorporeal circulation).

Methods Eighty-nine patients were included in the study. All patients were divided into: group 1 (n = 41) – coronary heart disease (CHD), group 2 (n = 47) – acquired heart diseases (AHD). All the operations were performed with normothermic nonpulsatile extracorporeal circulation (EC) with cold blood cardiopla (coronary artery bypass surgery in the group with CHD and prosthetics/plastic valves for the group with AHD). Systemic inflammatory response (SIRS) was defined by Bone and colleagues [1]: ischemia and reperfusion by lactate and oxygen status of arterial and mixed venous blood (StatProfile). We studied by enzyme immunonassay level (ELISA): high-sensitivity C-reactive protein (hsCRP), procalcitonin (PCT-Q) and STREM-1, using...
the set by Bender Medsystems, CanAg and Brahms PCT-Q. Data are presented as mean ± standard deviation.

Results All patients registered the increased level of hsCRP without significant difference between the two groups. At the point after the operation, the rate of hsCRP was significantly higher for the group AHD. Correlations were noted between levels of hsCRP and the frequency of occurrence of criteria for SIRS (r = 0.22 for the group of IHD, P = 0.03; r = 0.39 for the group AHD, P = 0.01). The odds ratio (OR) likelihood of SIRS complications on hsCRP was 2.4 in the group with CHD and 3.9 in the group with AHD. There was no significant difference between the rates of PCT for the corresponding points of comparison groups. The highest predictive value (OR = 2.9, P = 0.03) has a PCT in relation to the severity of SIRS in patients with AHD (infectious endocarditis and rheumatic heart disease). The sTREM-1 level was higher compared with the postoperative period (53.5 ± 8.8 vs. 77.8 ± 9.1 pg/ml, P = 0.005; 49.9 ± 6.7 vs. 87.5 ± 8.9 pg/ml, P = 0.004). We studied the correlation between the level of sTREM-1 and the frequency of occurrence of symptoms SIRS (r = 0.77 for the group of IHD, P = 0.002; r = 0.79 for the group AHD, P = 0.04). The OR sTREM-1 probability of SIRS complications was highest in comparison with all of the markers.

Conclusions sTREM-1 has the greatest diagnostic significance in relation to non-infectious SIRS in ischemia/reperfusion.

The normobaric oxygen paradox: does it increase haemoglobin?
S Theunissen1, D De Bels1, J Devriendt1, P Gernonpré1, P Lafaye1, J Valamsis2, T Snoeck3, P Meeus3, C Balestra3
1ISEK Environmental Physiology Laboratory, Brussels, Belgium; 2Brugmann University Hospital, Brussels, Belgium; 3Queen Astrid Military Hospital, Brussels, Belgium

Introduction A novel approach to increase erythropoietin (EPO) using oxygen has been reported in healthy volunteers. The purpose of this study is to investigate whether the EPO increase is sufficient to induce erythropoiesis.

Methods We compared exposure to daily versus every other day oxygen administration on haemoglobin variation during a 12-day period. Each subject underwent the two protocols at a 6-week interval period to achieve the same baseline values.

Results See Figure 1. Nine subjects underwent the study. We observed a significant increase in haemoglobin values in the every other day group compared with the each day group and with baseline. At the end of each day period, haemoglobin values increased to achieve a significant difference as compared with baseline. There was a significant rise of reticulocytes in the every other day group as compared with the each day group (182 ± 94% vs. 93 ± 34%, P < 0.001). These data provide demonstration of an enhanced production of erythrocytes.

Figure 1 (abstract P422). Comparison between haemoglobin variations after 30 minutes of 100% O2 breathing every day or every other day.

**Statistically significant difference from baseline (P <0.01) for oxygen breathing every other day (protocol B). ††Statistically significant difference from baseline (P <0.01) for Oxygen breathing each day (protocol A).

Conclusions The normobaric oxygen paradox seems effective to increase haemoglobin in non-anaemic healthy volunteers assuming there is a sufficient time interval between the two oxygen applications. This could permit interesting clinical applications in perioperative medicine as an adjunct therapy to EPO for blood predonation.

P423
Transfusion of red blood cells does not increase transcutaneous oxygen tension
O Schlager, M Gschwandtner, M Nikiardjam, R Koppensteiner, G Heinz
Medical University Vienna, Austria

Introduction We investigated the skin oxygen tension (tcpO2) of critically ill patients before, during and after transfusion (XF) of packed red blood cells (RBC).

Methods Nineteen critically ill patients (11 men, age 67 ± 15 years, SAPS II 60.1 ± 19) who received 2 U RBC due to hemoglobin (Hb) <8 g/dl underwent measurement of tcpO2 (TCM400; Radiometer Ltd,
Copenhagen, Denmark) at the dorsum of one hand. Each patient served as her/his own control (baseline, after XF of 1, and second RBC). Ventilation and pressors were kept constant. Patients with bleeding, in shock and with circulatory assists were excluded. Cardiac index (CI) was determined by FloTrac™/Vigileo™.

**Results**

Hb significantly increased (P <0.002), while tcpO₂ was not significantly different throughout XF (Figure 1; P = 0.72). Arterial pO₂ (86 ± 14 vs. 91 ± 11 vs. 88 ± 18 mMg, P = 0.68) and global hemodynamics (CI, P = 0.89; Figure 1; SVR: 822 ± 360 vs. 703 ± 233 vs. 941 ± 410, P = 0.13) did not change. Oxygen delivery (DO₂) significantly increased (644 ± 188 vs. 744 ± 234 vs. 818 ± 214 mL/minute, P = 0.049). Interestingly, central venous oxygen saturation (ScvO₂) decreased significantly during XF and did not completely recover until the end of XF (P <0.05 midst XF vs. baseline; Figure 1).

**Conclusions**

XF significantly increased Hb and calculated DO₂, but not tcpO₂. Increase in DO₂ occurred in the absence of changes in CI and oxygenation. ScvO₂ significantly decreased during XF but did not completely recover until the end of the study period.

Role of CD40 ligand in transfusion-related acute lung injury

PR Tuinman¹, M Gerards¹, G Jongsmay¹, L Boon², AP Vlaar², NP Juffermans³

¹Academic Medical Center, Amsterdam, the Netherlands; ²Bioceros, Utrecht, the Netherlands

**Introduction**

Transfusion-related acute lung injury (TRALI) is an important problem in the critically ill. CD40L has been implicated as a cofactor or even the cause of TRALI [1]. We hypothesized that blocking the binding of CD40-L to CD40 on alveolar macrophages may protect against lung injury in a murine model of TRALI. (2) Furthermore, we hypothesized that plasma sCD40L levels are elevated in TRALI patients compared with controls.

**Methods**

(1) Male BALB/c mice (n = 96) were challenged with monoclonal MHC-1 antibody (Ab), a previously used murine TRALI model [2]. In separate experiments, mice were pretreated with Ciglitazone, an inhibitor of the expression of CD40L on platelets, or anti-CD40L Ab, which antagonizes CD40L-CD40 interaction. Controls received vehicle or isotype Ab. After 2 hours, mice were killed and bronchoalveolar lavage fluid (BALF) was obtained. The wet lung to body weight ratio was calculated. Total protein, keratinocyte-derived chemokine (KC) and macrophase-inflammatory protein-2 (MIP-2) were measured in BALF. (2) Cardiac surgery patients were prospectively followed for the onset of TRALI (by applying the consensus definition). Sixteen TRALI cases were compared with controls (transfused patients not developing lung injury). Plasma levels of sCD40L were measured before surgery and at onset of TRALI.

**Results**

(1) Infusion of MHC-1 Ab resulted in pulmonary edema, accompanied by elevated BALF levels of total protein and KC and MIP-2 compared with infusion of isotype Ab (P <0.05 to all). Treatment with Ciglitazone or anti-CD40L Ab did not result in a decrease of pulmonary edema compared with MHC-1 Ab, nor did it reduce BALF KC levels (33 ± 6.1 vs. 27 ± 19 vs. 13 ± 9.4 mg/ml respectively) and MIP-2 levels (5.3 ± 3.0 vs. 1.5 ± 1.7 vs. 2.0 ± 2.9 ng/ml respectively). (2) Surgery resulted in a decrease in CD40(L) levels, with a concomitant decrease in platelet count. We found no difference in plasma levels of sCD40L between cardiac surgery patients developing TRALI and controls (275 ± 192 vs. 258 ± 346 and 93 ± 82 vs. 93 ± 123 pg/ml respectively, NS).

**Conclusions**

CD40L does not play a role in this model of antibody-mediated TRALI. Moreover, sCD40L levels are not different in cardiac surgery patients developing TRALI compared with transfused controls, further suggesting that sCD40L is not a mediator of TRALI.

Central venous to arterial carbon dioxide gap as an indicator of oxygen debt in isovolemic anemia

S Kocsi, G Demeter, D Erces, I Kaszaki, Z Molnar
University of Szeged, Hungary

Introduction Anemia can cause an imbalance in oxygen delivery (DO,) and consumption (VO2), which may be difficult to detect. Recently the venous to arterial carbon dioxide difference has been shown to be increased (>5 mmHg) in certain critically ill conditions [1,2]. No study has yet investigated its significance in severe normovolemic anemia. Therefore, the aim of this study was to investigate the course of the central venous to arterial carbon dioxide gap (dcvCO2) in isovolemic anemia.

Methods An experimental animal study on anesthetized Vietnamese mini-pigs. After splenectomy, mini-pigs (n = 13, weight range: 18 to 30 kg) were bled in five stages (~10% of estimated blood volume/5 minutes, T0 to T5) and blood loss was replaced by the same volume of colloid, after which hemodynamic measurements and blood gas analysis were performed.

Results The fall of hemoglobin was significant from the first bleeding, from T0 to T5, median = 125 (interquartile range = 113 to 134) to 49 (43 to 55) g/l, P < 0.05, respectively. Despite a significant increase in cardiac index by T5 (I'c = 2.6 (2.3 to 2.8) vs. T0 = 3.3 (2.7 to 3.6) l/minute/m2, P < 0.05), which remained so for the rest of the experiment, the O2 extraction (VO2/DO2) increased significantly only from T0 to T5 (90 (80 to 104) vs. 72 (55 to 91)%, P < 0.05). There was a strong significant correlation between VO2/DO2 and dcvCO2: r = 0.65, r2 = 0.43, P < 0.001. Furthermore, dcvCO2 with a cut-off value >5 mmHg had a sensitivity of 69% and specificity of 82% to show a VO2/DO2 <30%, and receiver operating characteristics showed an area under the curve of 0.787 ± 0.054 (CI: 0.682 to 0.892), P < 0.05. Anemia was accompanied by a significant increase in dcvCO2, from T0 = 5 (3 to 9) to T5 = 6 (6 to 11) mmHg, P < 0.05. There was a strong significant correlation between VO2/DO2 and dcvCO2: r = 0.65, r2 = 0.43, P < 0.001. Furthermore, dcvCO2 with a cut-off value >5 mmHg had a sensitivity of 69% and specificity of 82% to show a VO2/DO2 <30%, and receiver operating characteristics showed an area under the curve of 0.787 ± 0.054 (CI: 0.682 to 0.892), P < 0.05, for the same VO2/DO2 threshold.

Conclusions To our best knowledge, this is the first study to show that dcvCO2, could be used to detect oxygen debt in anemic anemia.

Red blood cell transfusion thresholds in pediatric septic patients

O Karam1, M Tucci1, T Ducruet1, H Humel1, J Lacroix2, F Gauvin2
1Hopitaux Universitaires de Genève, Switzerland; 2CHU Sainte-Justine, Montréal, Canada

Introduction In children with severe sepsis or septic shock, the optimal red blood cell (RBC) transfusion threshold is unknown. We analyzed the subgroup of patients with sepsis in the TRIPICU (Transfusion Requirements in Pediatric Intensive Care Units) study in order to determine the impact of a restrictive versus liberal transfusion strategy on clinical outcome.

Methods This study is a subgroup analysis of a prospective multicenter randomized controlled trial (TRIPICU). One hundred and thirty-seven patients whose hemoglobin levels were <7 g/dl were randomized to receive RBC transfusion if their hemoglobin dropped below either 7.0 g/dl (restrictive group) or 9.5 g/dl (liberal group).

Results In the restrictive group (69 patients), 30 patients did not receive any RBC transfusion, whereas only one patient in the liberal group (68 patients) was never transfused (P <0.01). No clinically significant differences were found for the occurrence of new or progressive multiple organ dysfunction syndrome (18.8% vs. 19.1%; P = 0.97), for PICU length of stay (P = 0.74) or PICU mortality (P = 0.44) in the restrictive versus liberal group.

Conclusions In this subgroup analysis of stable septic children, we found no evidence that a restrictive red-cell transfusion strategy, as compared with a liberal one, increased the rate of new or progressive MODS. On the other hand, a restrictive transfusion threshold significantly reduced exposure to blood products. Our data suggest that a hemoglobin level of 7 g/dl may be safe for stabilized septic children but further studies are required to support this recommendation.

Accuracy of a continuous non-invasive hemoglobin monitor in the ICU

D Frasca, C Dahyot-Fizelier, C Karen, Q Levrat, N Soumagne-Vialle, M Boisson, B Debaene, O Mimoz
CHU Poitiers, France

Introduction The non-invasive pulse CO-oximeter provides an immediate and continuous estimation of hemoglobin concentration non-invasively, and so has the potential to improve ICU patient care. We determined whether non-invasive hemoglobin measurement by pulse CO-oximetry could provide clinically acceptable absolute and trend accuracy in critically ill patients, compared with other invasive methods of hemoglobin assessment available at bedside and the gold standard, the laboratory analyzer.

Restrictive transfusion was associated with increased pulmonary levels of plasmigen activator inhibitor-1 compared with nontransfused controls with a further increase after multiple transfusions (P <0.001; 3.4 (1.2) vs. 4.4 (1.4) vs. 6.3 (2.5) ng/ml, respectively). Concomitantly, levels of plasmigen activator activity (PAA%) were lower (P <0.001; 42 (6.5) vs. 34 (6.5) vs. 32 (7.8)%, respectively), indicating impaired fibrinolysis. In the systemic compartment, transfusion was associated with a significant increase in levels of TNFα, TATc and PAA (P <0.05).

Conclusions Transfusion during cardiac surgery is associated with activation of inflammation and coagulation in the pulmonary compartment of patients who do not meet TRALI criteria, an effect that was partly dose dependent, suggesting transfusion as mediator of acute lung injury. These pulmonary changes were accompanied by systemic coagulopathy.
Methods A prospective study was conducted in the surgical ICU of a university teaching hospital. Blood samples from subjects continuously monitored with pulse CO-oximetry (SpHb) were analyzed for hemoglobin concentration determination by a point-of-care device (HemoCue301, HbHC), satellite laboratory CO-oximetry (Siemens RapidPoint 450, HbABG) and a laboratory hematology analyzer (Sysmex XT-2000i, thbH), which was considered the reference device. Hemoglobin values reported from the invasive methods were compared with the values reported by the Masimo Radical-7 Pulse CO-Oximeter at the time of the blood draw.

Results Sixty-two patients requiring 471 blood samples were included. Compared with the reference method, the bias and limits of agreement were 0.0 ± 1.0 g/dl for SpHb, 0.3 ± 1.3 g/dl for HbHC and 0.9 ± 0.6 g/dl for HbABG compared with the reference device. Accuracy assessed with ARMS was 0.8 g/dl for SpHb and 1.1 g/dl for HbABG and HbHC. Pulse CO-oximetry showed similar trend accuracy as CO-oximetry, whereas the point-of-care device did not follow the trend of the laboratory device as well as the other analyzers. See Table 1.

Conclusions When compared with laboratory reference values, hemoglobin measurement with pulse CO-oximetry has absolute and trending accuracy similar to widely used, invasive methods such as CO-oximetry and a point-of-care device. Hemoglobin measurement with pulse CO-oximetry has the additional advantages of providing continuous measurements, non-invasively, which may facilitate hemoglobin monitoring in the ICU.

P430 Safety and effectiveness of different treatment regimes with tranexamic acid in elective cardiopulmonary bypass patients JL Iribarren, JJ Jimenez, M Brousard, C Llanos, J Herrera, L Lorenzo, R Perez, S Palomo, N Perez, L Lorente, M Mora, R Martinez

Introduction Although tranexamic acid (TA) has been effective in reducing bleeding after cardiac surgery, the TA dosing scheme varies in a dose-dependent fashion. A cohort study. The TA treatment regimes were: A: none, B: 40 mg/kg before CPB, C: 25 mg/kg before and 25 mg/kg after CPB, and D: 40 mg/kg before and after CPB. Demographic variables, comorbidity, perioperative clinical data, and postoperative outcomes (bleeding, RIFLE classification, seizures, stroke and mortality) were recorded. SPSS v15 was used.

Results We studied four hundred and five patients (66, 80, 179 and 80 in the A, B, C and D groups, respectively). Surgical procedures were 209 (52%) coronary artery bypass grafting, 135 (33%) valvular, 41 (10%) combined surgery and 20 (5%) other procedures. The 24-hour postoperative bleeding was: A: 992 (95% CI = 808 to 1,177) ml; B: 829 (95% CI = 708 to 950) ml; C: 686 (95% CI = 607 to 765) ml; and D: 671 (95% CI = 550 to 793) ml (F: 18.98, P < 0.001). The post-hoc analysis (Scheffe test) showed significant differences between group A versus group C (P = 0.002), and between group A versus group D (P = 0.003). The 24-hour postoperative red blood cell requirements were: A: 384 (95% CI = 248 to 520) ml; B: 200 (95% CI = 119 to 280) ml; C: 253 (95% CI = 184 to 323) ml; and D: 156 (95% CI = 82 to 231) ml (χ²: 8.24 P = 0.041). We did not find significant differences after surgery between groups regarding the development of stroke (1.3 to 2.5%), RIFLE: I (2.5 to 7.5%) and seizures (0 to 2.5%), even though seizures were present in a dose-dependent fashion.

Conclusions A dose higher than 25 mg/kg before and after CPB does not show a clinically relevant decrease in blood loss with a potential increase of adverse events, particularly the observation of seizures.
test up to 1 day following FFP start. Patients dying within 72 hours surrounding FFP were excluded. Kaplan–Meier survival curves were estimated and time to death was assessed using Cox proportional hazards models. In sensitivity analysis, an INR threshold ≤1.5 was used to account for clinical practices that aim to avoid adverse outcomes (for example, thrombosis) of certain co-morbidities.

Results A total of 405 patients met the selection criteria (mean age 75 years, 53% male, and 67% remained uncorrected. Overall, 19% of patients died within 90 days of hospital admission, with a higher proportion of uncorrected versus corrected patients dying (24% vs. 13%, P = 0.013). In Cox regression analysis, patients with a first elevated INR value >4 (HR = 2.21; 95% CI = 1.36 to 3.60), with an ICH bleeds versus gastrointestinal or other bleed (HR = 2.08; 95% CI = 1.27 to 3.40), and with uncorrected INR (HR = 2.33; 95% CI = 1.30 to 4.16) were significantly more likely to die within 90 days of admission. In a sensitivity analysis (correction defined as INR ≤1.5), 39% remained uncorrected within 24 hours of FFP administration, with factors predicting 90-day mortality remaining robust in regression analysis.

Conclusions Among ACR major bleed patients, not correcting to either INR ≤1.3 or INR ≤1.5 with FFP is associated with an increased rate of mortality at 90 days. Further assessment of co-morbidities associated with hemostasis and other predictors of mortality risk in this population is warranted.

P434
Thromboembolic risks of recombinant factor Vila use in warfarin-associated intracranial hemorrhage
S Chou, X Cai, R Konisgberg, L Bresette, G Henderson, F Sorond, A Ropper, S Feske
Brigham and Women’s Hospital, Boston, MA, USA

Introduction Recombinant factor Vila (rFVila) may produce rapid hemostasis in warfarin-associated intracerebral hemorrhage (WICH) but may carry high thromboembolic risks. We compared baseline thromboembolic risk factors and thromboembolism rates in WICH patients treated with rFVila to those treated with FFP and vitamin K alone.

Methods We identified 45 consecutive WICH patients treated with rFVila and 34 treated with FFP and vitamin K, and compared their incidence of pre-existing thromboembolic risk factors, troponin elevation, EKG changes, ischemic stroke, pulmonary embolism (PE), and deep vein thromboses (DVT).

Results Both rFVila-treated and control WICH patients have high prevalence of pre-existing thromboembolic risk factors including atrial fibrillation (73% vs. 68%), DVT/PE (10% vs. 6%), coronary artery disease (CAD) (38% vs. 32%), and abnormal EKG (78% vs. 85%). Troponin elevation is common in WICH and incidence of troponin elevation (47% vs. 41%) and clinically significant myocardial infarction (MI) (13% vs. 6%) are similar between treatment groups. Past history of CAD (P = 0.0061) and baseline abnormal EKG (P = 0.02) were independently associated with clinically significant MI following WICH. Incidence of DVT/PE (2% vs. 9%) and ischemic stroke (2% vs. 0%) are comparable between rFVila-treated and control groups. Recombinant FVila-treated patients had lower mean INR at 3 (P = 0.0001) and 6 hours (P <0.0001) and received fewer units of FFP transfusion (3 vs. 5; P = 0.003).

Conclusions Recombinant FVila use in WICH is not associated with increased thromboembolic complications compared with FFP and vitamin K alone and may decrease the quantity of FFP use. A prospective randomized study is necessary to determine whether rFVila improves outcome of WICH.

Monitoring of coagulation in patients after abdominal cancer surgery
O Tarabrin1, V Suslov1, S Kalinichuk2, S Shcherbakov1, D Gavrychenko1
1Odessa National Medical University, Odessa, Ukraine; 2Odessa Regional Clinical Hospital, Odessa, Ukraine

Introduction Despite the evidence of perioperative hypercoagulability in cancer patients, there are no consistent data evaluating the extent, duration, and specific contribution of platelets and procoagulatory proteins by in vitro testing. This study compared efficacy of haemoscoelastography (HVG) versus thromboelastography for monitoring of coagulation imbalance.

Methods A total of 356 patients undergoing open surgery for abdominal cancer received HVG, a viscoelastic test, which measures clot formation and includes information on the cellular as well as the platelet coagulation system. We examined the effectiveness of coagulation tests. A complete coagulation screen activated clotting time (ACT), thromboelastography (TEG) and HVG were performed before surgery, at the end of surgery, and bemiparin anticoagulation monitoring on postoperative days 1, 2, 3, and 7. These were analyzed for the reaction time and the maximal amplitude (MA).

Results We calculated the elastic shear modulus of standard MA and HVG MA, which reflect the total clot strength and procoagulatory protein component, respectively. The difference was an estimate of the platelet component. There was a 16% perioperative increase of standard MA and HVG MA, which reflects the total clot strength and procoagulatory protein component, respectively. The difference was an estimate of the platelet component. There was a 16% perioperative increase of standard MA and HVG MA, which reflects the total clot strength and procoagulatory protein component, respectively. The difference was an estimate of the platelet component. There was a 16% perioperative increase of standard MA and HVG MA, which reflects the total clot strength and procoagulatory protein component, respectively. The difference was an estimate of the platelet component. There was a 16% perioperative increase of standard MA and HVG MA, which reflects the total clot strength and procoagulatory protein component, respectively. The difference was an estimate of the platelet component. There was a 16% perioperative increase of standard MA and HVG MA, which reflects the total clot strength and procoagulatory protein component, respectively. The difference was an estimate of the platelet component. There was a 16% perioperative increase of standard MA and HVG MA, which reflects the total clot strength and procoagulatory protein component, respectively. The difference was an estimate of the platelet component. There was a 16% perioperative increase of standard MA and HVG MA, which reflects the total clot strength and procoagulatory protein component, respectively. The difference was an estimate of the platelet component. There was a 16% perioperative increase of standard MA and HVG MA.
Conclusions Postoperative hypercoagulability, occurring for at least 1 week after major cancer abdominal surgery, may be demonstrated by HVG. Hypercoagulability is not reflected completely by standard coagulation monitoring and TEG and seems to be predominantly caused by increased platelet reactivity.

Overuse of coagulation parameter testing in critically ill patients
V Ribeha, F Lauzier, MN Cote, AF Turgeon
CHA-Hôpital de l’Enfant-Jésus, Université Laval, Quebec, Canada

Introduction The international normalized ratio (INR) is one of the most commonly ordered laboratory tests in the ICU. Recently, it was raised that laboratory tests are widely overused in critically ill patients. We hypothesized that most INRs are inappropriately ordered and could lead to inadequate frozen plasma (FP) transfusion.

Methods We performed a retrospective cohort study in a 24-bed medical–surgical ICU of a Canadian teaching hospital. Patients with ≥1 INR testing admitted between 1 January and 30 June 2009 were randomly selected. Admission diagnosis, APACHE II score, drugs affecting coagulation, liver function, invasive procedures, recent or planned surgery, and recent or current bleeding were recorded. INRs ordered for warfarin adjustment were excluded. The primary endpoint was the proportion of inappropriate INRs, based on a blinded assessment of the clinical context by two independent investigators.

Secondary endpoints were contributing factors to INR ordering and impact on FP transfusion. We used a standardized case report form. Inter-rater agreement was evaluated using weighted kappa. A third independent investigator resolved disagreement. We used the Student t and chi-square tests to compare continuous data and proportions. We obtained ethics approval.

Results We included 43 patients (mean age 61.9 ± 16.0, APACHE II score 20.2 ± 8.6, 53.5% males) admitted for nontraumatic bleeding (41.9%), respiratory failure (16.3%), trauma (11.6%), sepsis (11.6%) or other reasons (18.6%). A total of 208 INRs were analyzed, representing 41.9, 53.5% males) admitted for nontraumatic bleeding.

Nearly 60% of INR orders were inappropriate. Patients on i.v. heparin, not on vasopressors, and with low APACHE II score were more likely to have inappropriate INRs. Despite no FP transfusion following inappropriate INRs, rationalizing INR testing is warranted to decrease associated costs and resource utilization.

P437
Applying a new method for studying the functional state of hemostasis in clinical practice
O Tarabrin1, T Tyutrin1, S Kalinchuk1, A Turenko1, S Shcherbakov1, G Davyenkochn1
1Odessa Medical University, Odessa, Ukraine; 2Siberian State Medical University, Tomsk, Russia; 3Odessa Regional Clinical Hospital, Odessa, Ukraine

Introduction It is known that deep vein thrombosis of lower extremities and pulmonary embolism occupies an important place in the structure of postoperative morbidity and mortality.

Methods After ethics approval and informed consent, we studied the functional state of hemostasis in a group of 40 healthy volunteers who were not receiving drugs affecting coagulation and in 37 patients with postphlebothrombotic syndrome (PPTS). In patients with PPTS we conducted baseline studies of coagulation state and daily monitoring of dynamic changes in the functional state of hemostasis, a comparative evaluation of performance low-frequency piezoelectric vibration hemoviscoelastography (LPHV) and the platelet aggregation test (PAT), standard coagulation tests (SCT), and thromboelastogram (TEG).

Results It was found that the LPVH correlated with SCT, PAT and TEG. However, our proposed method is more voluminous: indexes ICC (the intensity of the contact phase of coagulation), t1 (the time the contact phase of coagulation), and AO (initial rate of aggregation of blood) were consistent PAT indexes; indexes ICD (the intensity of coagulation drive), CTA (a constant thrombin activity) and CIP (the clot intensity of the polymerization) for SCT and TEG. In addition, the advantage of this method is to determine the intensity of fibrinolysis – with indicator IRLS (the intensity of the retraction and clot lysis).

Conclusions LPVH allows one to make the total assessment of all parts of hemostasis: from initial viscosity and platelet aggregation to coagulation and lysis of clots, as well as their interaction. These data are objective and informative, as evidenced by close correlation with the performance of traditional coagulation methods.

P438
Comparison of point-of-care thrombelastography versus conventional coagulation tests in the emergency department management of trauma
V Jeger1, S Willi1, T Lüli1, L Omert2, A Orr1, MA Popovsky1, H Zimmermann1, AK Exadaktylos2
1University Hospital Inselspital Bern, Switzerland; 2Haemonetics Corporation, Braintree, MA, USA

Introduction To guide the administration of blood products, coagulation screening of trauma patients should be fast and accurate.

Conventional coagulation tests (CCT) are frequently not useful in the initial assessment of multiply injured patients, due to the delay in availability of results. The purpose of this study is to determine whether Rapid thrombelastography (RapidTEG®) results in 15 minutes correlate with Kaolin TEG or CCT.

Methods A 6-month prospective observational study of adult patients with suspected multiple injuries was conducted at a Level 1 trauma center of a university hospital. TEG, RapidTEG®, and CCT (INR, aPTT, TT, fibrinogen, platelet count) were performed within 10 minutes of the patient’s arrival. Physicians blinded to TEG/RapidTEG® results made the decision to transfuse based on clinical evaluation and prior threshold (cut-off) values for CCT. Cut-off values for RapidTEG® were retrospectively assessed.

Correlations between TEG and CCT and between TEG and RapidTEG® parameters were calculated, as well as sensitivity and specificity of CCT and RapidTEG® for any blood product transfused on day 1.

Results Seventy-six predominantly blunt trauma (96%, n = 73) patients comprised the dataset. The mean ISS was 18. Only weak correlation existed between CCT and relevant TEG parameters (r = 0.097 to 0.615). Strong correlation exists between Kaolin TEG and RapidTEG® for K, MA, and LY30 (r = 0.844 to 0.988). At the predetermined cut-off points for treatment in trauma, CCT demonstrated poor sensitivity. Cut-off points for RapidTEG® demonstrated good sensitivity and specificity: RapidTEG*: Rapid K (seconds) 1.2: 80.0%; 59.2%; 0.785 (cut-off; sensitivity; specificity; AUC), Rapid angle (°) 74.7; 84.0%; 56.9%; 0.765, Rapid MA (mm) 61.5; 72.0%; 71.4%; 0.745. CCT: TT (seconds) 15; 28.6%; 88.9%; 0.529, aPTT (seconds) 60; 4.8%; 97.8%; 0.735, INR 1.5; 19.0%; 96.0%; 0.730.

Conclusions In this study of severely injured blunt trauma patients, RapidTEG® can be utilized in lieu of kaolin TEG to provide faster test results. Cut-off points for treatment can be determined with RapidTEG to provide improved sensitivity and specificity compared with CCT with respect to blood product transfusion.

**Effect of hyperthermia on coagulation functions in Sprague–Dawley rats with untreated hemorrhagic shock**

KH Park, JJe National University Hospital, Jeju, South Korea

**Introduction** Acute coagulopathy, hyperthermia, and acidosis are known as the lethal triad of major trauma patients. Major trauma patients with hyperthermia and acidosis developed clinically significant bleeding despite adequate transfusion [1]. Recent animal experimental studies reported that hyperthermia is associated with improved survival in controlled hemorrhagic shock [2,3]. Post-traumatic hyperthermia is an unproven therapy unlike hyperthermia as a postcardiac arrest care. The objective of this study was to investigate the effect of hyperthermia on coagulation function in untreated hemorrhagic shock with major trauma.

**Methods** Thirty-two male Sprague–Dawley rats were divided into four groups randomly: Group 1 with normothermia (control, 37 to 38°C); Group 2 with hyperthermia (33 to 34°C on rectal temperature); Group 3 with hypothermic hemorrhagic shock; Group 4 with normothermic hemorrhagic shock. Hemorrhagic shock was induced by splenic laceration or blood shedding. Coagulation functions were measured by rotation thrombelastometry (ROTEM®). The clotting time, clot formation time (CFT), and maximum clot firmness (MCF) were measured at baseline, after 1 hour shock, and after 1 hour resuscitation. They were compared among the four groups using the Kruskal–Wallis test with Bonferroni correction, and the Friedman test was used to detect the differences in the repeated measures in the same group, taking P < 0.05 as a significant level.

**Results** No significant differences showed among the groups at baseline. CFT after the shock period of group 2 was longer than that of group 4. MCF after resuscitation of group 2 was higher than that of groups 3 and 4. When the factors were compared as a time process, CFT and MCF after shock and resuscitation of group 3 decreased significantly compared with baseline. Four in group 3 and two in group 4 died during 48 hours of observation.

**Conclusions** Although it took a shorter time to form a clot in normothermic shock compared with hyperthermia, clot firmness was poorer in hemorrhagic shock. In addition, clot firmness was significantly worse in the shock period and after resuscitation in the hypothermic shock group. Only hyperthermia does not deteriorate coagulation, but hyperthermia combined with hemorrhagic shock deteriorates coagulation.

**Sepsis: thrombocytopenia is bad, not recovering thrombocytopenia is too bad**

W Favier, T Boechat

Universidade Severino Sombre, Vassouras, Brazil

**Introduction** Thrombocytopenia is a prognostic marker in the critically ill population [1], affecting, indistinctly, patients presenting low platelet count on admission or developing it during their stay in the ICU. It has been shown that a drop in platelet count to ≤50% of admission is associated with high death rates [2]. We aimed to observe the outcome of thrombocytopenic septic patients in our ICU.

**Methods** A retrospective observational cohort study in an 11-month period (August 2009 to July 2010) in an eight-bed medical-surgical ICU at a university hospital. This study included patients who fulfilled the criteria for sepsis as defined in the Surviving Sepsis Campaign and excluded those who spent less than 24 hours in the ICU. Thrombocytopenia (T) was defined as platelet count <150 x 10^9/l, recovering thrombocytopenia (RT) platelet count returning to >150 x 10^9/l and not recovering thrombocytopenia (NRT) platelet count consistently <150 x 10^9/l. We focused on the demographic data, APACHE II score, platelet count on admission, platelet count during stay and platelet count at the time of discharge from ICU. The primary outcome was ICU mortality.

**Results** Complete data were available for 62 patients. Six were excluded. Twenty-eight males (50%), mean age 58 years (12 to 88 years), median APACHE II score 16.7 (interval 2 to 37). During the sepsis course 34 patients (60.7%) developed T, 15 (44.1%) had a drop in platelet count to <50% of admission and NRT occurred in 18 (53%). Mortality in the T group was 76.4% (RR = 1.9; 95% CI = 1.17 to 2.74; P < 0.01), in platelet count drop to <50% of admission group it was 93.3% (RR = 1.47; 95% CI = 1.02 to 2.2; P < 0.05), and in RT patients 50% survived to be discharged from the ICU. In the NRT group the mortality was 100% (RR = 2; 95% CI = 1.3 to 3; P < 0.001) while in nonthrombocytopenics the total mortality was 40.9% (P < 0.01). In T group patients the APACHE II score did not predict accurately the mortality risk. In both APACHE II groups (>22 (P = 0.007) or <22 (RR = 1.7; P = 0.05)) thrombocytopenia was highly associated with death. The ICU overall mortality in this period was 32%.

**Conclusions** Thrombocytopenia — and its behavior — is a simple prognostic marker for ICU mortality independently of and complementary to established severity of disease scores. For septic patients thrombocytopenia is bad, not recovering thrombocytopenia is worse.

**Thrombocytopenia: incidence and clinical impact on ICU mortality**

M Kompoti, M Michalía, P Peppa, F Nanou, M Charitidi, M Sartzí, I Vassiliadis, G Kallitsí, P Clouva-Molyvdas

Thriassio General Hospital of Eleusis, Athens, Greece

**Introduction** The prognostic significance of thrombocytopenia in critically ill patients has not been thoroughly explored. Our study aimed at investigating the incidence of thrombocytopenia among ICU patients, its association with ICU-acquired infection and its clinical impact on ICU mortality.

**Methods** All patients admitted to the ICU were prospectively followed with daily platelet (PLT) count measurement until ICU outcome. Thrombocytopenia was defined as PLT count lower than 150,000/mm^3 and severe thrombocytopenia as PLT count lower than 20,000/mm^3. Data were analyzed with one-way ANOVA and logistic regression with statistical significance set at P < 0.05.

**Results** We studied 169 consecutive patients (119 males, 50 females) aged (mean ± SD) 53.4 ± 19.8 years, with admission APACHE II score 22.7 ± 5.3. Thrombocytopenia during ICU stay was recorded in 101 patients (59.8%). Emergency surgical and trauma patients displayed the highest incidence of thrombocytopenia (77.3% and 72.1%, respectively). Emergency surgical and medical patients displayed the highest of severe thrombocytopenia (18.2% and 10.6%, respectively). Trauma and emergency surgical patients developed thrombocytopenia earlier during the ICU stay (that is, after 4.9 and 5.1 days, respectively) compared with medical and elective surgical patients (that is, after 13.3 and 10.9 days, respectively) (P = 0.001). Thrombocytopenia was more often recorded in patients with ICU-acquired infection compared with patients without infection. In particular, severe thrombocytopenia was recorded in 18.9% of patients with bloodstream infection and 9.0% of patients with other ICU-acquired infection. ICU mortality was significantly higher in patients who developed thrombocytopenia compared with patients with normal PLT counts throughout the ICU stay (30% vs. 9.4%, P = 0.002). In a logistic model adjusted for age, gender, admission diagnosis, admission APACHE II score and the occurrence of ICU-acquired infection, thrombocytopenia was independently associated with ICU mortality (P = 0.017) and the degree of PLT count decrease significantly increased the ICU mortality in a dose-dependent manner; that is, odds ratios of 3.4 for PLT 100,000 to 150,000/mm^3, 3.5 for PLT 50,000 to 100,000/mm^3, 14.9 for PLT 20,000 to 50,000/mm^3 and 25.2 for PLT below 20,000/mm^3.
Conclusions Thrombocytopenia was a common finding in our sample of ICU patients. Although the time of occurrence and the degree of PLT count decrease varied, reflecting a wide spectrum of pathogenic mechanisms, thrombocytopenia was independently associated with ICU mortality in a dose-dependent manner.

P442
Sepsis-induced thrombocytopenia: early prediction and modifiable mortality
G Geargiev, S Milanov, V Todorova, L Kozarov, M Milanov
Pirinogov Emergency Institute, Sofia, Bulgaria

Introduction Thrombocytopenia is a common problem in the ICU, considered to be associated with increased morbidity and mortality. Risk factors for sepsis-induced thrombocytopenia have not been yet specified. Our study focuses on its development and consequences in the general ICU.

Methods A prospective observational study was conducted including all cases of sepsis for a 2-year period. Data on demographics, primary diagnosis and source of infection, current infectious pathogens, presence/severity of shock and outcome were cross-tabulated according to the presence and severity of thrombocytopenia. Effects of immunotherapy and substitution with thrombocyte concentrate on outcome were also tested. Analyses of disease prescription, length of ICU stay (LOS), severity and dynamics of organ dysfunction/disease/systemic inflammation (serum creatinine levels, SOFA, SAPS II, SIRS, lung injury score) for each group of patients was performed.

Results The study included 118 patients with thrombocytopenia of variable severity (39.33% out of 300 septic patients). The following independent prognostic factors for supervening thrombocytopenia (reported with respective RR and 95% CI) were identified: platelet count <150 g/l – prescription >48 hours (1.31; 1.02 to 1.67), SOFA score on inclusion >6 (1.36; 1.02 to 1.78), ΔSOFA >5 (2.77; 1.27 to 3.55), initial SAPS II exp. score >5.5 (1.39; 1.04 to 1.82), LPS >1.75 (1.56; 1.13 to 2.19), serum creatinine >12 μmol/l (2.38; 1.72 to 3.36), Gram-positive infectious pathogen, especially if Gram-positive co-infection or if concomitant invasive candidiasis (1.44, 1.08 to 1.94; 1.9, 1.33 to 2.46 and 2.60; 1.31 to 3.02), Streptococcus spp. infection (2.04; 1.17 to 3.64), disruption of the lower GIT (1.48; 1.06 to 1.97), polytrauma (0.39; 0.22 to 0.65); and platelet count <20 g/l – urosepsis (6.53; 1.76 to 16.96), soft tissue infection (9.87; 2.75 to 22.07), initial SAPS II exp. score >6.2 (4.90; 2.02 to 11.71), SOFA score on inclusion >8 (6.52; 2.68 to 15.04), female sex (1.74; 1.13 to 2.26). Mortality was significantly higher for the thrombocytopenic patients (66.95% vs. 41.76%, P = 0.000), except for those who underwent specific therapy (37.5%, P = 0.000).

Conclusions Sequential measurement of biochemical and hematological parameters, mainly AST, IL-6, WBC, CRP and D-dimers, can help in early diagnosis of sepsis in patients after extensive operation such as esophagectomy. On the contrary, TEG does not seem to be helpful in differentiation of SIRS/sepsis during the early postoperative period. However, it seems to be useful after the fifth postoperative day.

Acknowledgements Supported by grant agency of Charles University No. 21509.

Use of thromboelastography in severe sepsis: a case–control study
A Cortegiani, L Marino, F Montalto, M Milana, A Di Benedetto, L Vento, SM Raineri
University of Palermo, Italy

Introduction Thromboelastography (TEG) is a global test of coagulation that records the viscoelastic changes in blood during clot formation. Cardiosurgery and liver transplantation are established fields of application for TEG. Severe sepsis is often characterized by an imbalance of the haemostatic equilibrium between clot formation and fibrinolysis in favor of a procoagulant status, especially in the first phase. A shift was gained in vitro due to coagulation factor consumption which TEG-detected variable is best correlated with sepsis. The aim of this study is to clarify this correlation.

Methods We enrolled 62 patients in an observational study: 31 severe sepsis (ACCP/SCCM sepsis criteria plus two organ dysfunction at least) and 31 postoperative patients (without sepsis criteria), all admitted to our ICU. Patients with primary hematologic dysfunction/malignancy were excluded. The SOFA score was registered before enlistment. We obtained a 5 ml whole blood sample into a citrate 0.15 M test tube within 12 hours of diagnosis in the sepsis group or surgery in the postoperative group from each patient. A sample of 340 μl blood were extracted from each sample and put into a heparinase cup; coagulation was initiated with the addition of 20 μl CaCl2 0.2 M. All of the tests were performed by Haemoscope® TEG5000. According to TEG analysis, r, k, α-angle, MA, G, A, lysis 30 and coagulation index were compared between the two groups using the t test.

Results The mean age in the sepsis group was 59.8 whereas it was 62.2 in the postoperative group. The SOFA score was statistically different between the two groups (t = 3.359; P = 0.0015), being higher in the sepsis group. The α-angle parameter was found to be statistically significant higher in the postoperative group than in the sepsis group (t = 2.240; P= 0.0288).

No significant differences were found between the other TEG parameters.
Conclusions According to our data, there is no difference in TEG parameters between severe sepsis and postoperative patients apart from the α-angle, which seems to be lower in the first group. The α-angle is supposed to be high in the procoagulant state; our result could be thought of as linked to the late phase characterizing our severe sepsis group wherein factor consumption coagulopathy could occur.

Effect of anemia on coagulation and platelet function: a whole blood in vitro study
G Scharbert1, L Wetzel1, L Berlinger1, S Kozek-Langenecker2
1Medical University Vienna, Austria; 2Evangelical Hospital, Vienna, Austria

Introduction It is known that red blood cells are involved in hemostasis. They can support and improve coagulation in different ways. Therefore recommendations are given for red blood cell transfusions in anemic patients with massive bleeding to reach a hemoglobin concentration of 8 to 10 g/dl. Although blood transfusions can be life-saving, a number of negative or even potentially life-threatening effects are described.

Methods In this study we investigated the effect of anemia on platelet function and plasmatic hemostasis with two different point-of-care methods: the multiple electrode aggregometry Multiplate® (MEA) and the rotational thrombelastometry ROTEM®. Blood was taken from 13 healthy volunteers to arrange in vitro anemia-series with 10, 7 and 3 g/dl hemoglobin. For the MEA we applied the agonists collagen, arachidonic acid, adenosine diphosphate (ADP), thrombin-receptor-activating peptide (TRAP) and ristocetin. For the ROTEM® analysis we used the tests EXTEM, INTEM and FIBTEM.

Results The MEA showed significantly increased velocity of platelet aggregation in anemic blood samples. The agonists TRAP and ADP demonstrated the highest effects. The Aggregation Units and the area under the curve were not influenced by anemia. The ROTEM® analysis displayed significantly an amplified maximum clot firmness (MCF), a shortened clot formation time (CFT) and an increased α-angle. The CFT and lysis index at 30 minutes did not show any changes through lowering hemoglobin. The calculated effect of platelets on ROTEM® coagulation (MCFplatelet = MCFEXTEM – MCFFIBTEM) was unchanged.

Conclusions In our study platelet function in anemic blood was observed with the MEA for the first time. Our results showed accelerated platelet aggregation through lowering hemoglobin. Our findings of a hypercoagulable profile in ROTEM® are in accordance with earlier observations. Future clinical studies are needed to evaluate risk of bleeding or hypercoagulability in anemic patients.

Effect of pH levels on platelet aggregation and coagulation: a whole blood in vitro study
G Scharbert1, G Franta1, L Wetzel1, S Kozek-Langenecker2
1Medical University Vienna, Austria; 2Evangelical Hospital, Vienna, Austria

Introduction The combination of acidosis, hypothermia and coagulopathy is associated with high mortality in polytrauma [1]. Acidosis impairs coagulation [2]. Whether acidosis leads to a reduced platelet function has not so far been evaluated.

Methods In this in vitro study we evaluated the effects of pH levels (7.6, 7.4, 7.2, 7.0 and 6.8) on platelet aggregation and coagulation with human whole blood of healthy male volunteers. We used multiple electrode aggregometry (MEA) Multiplate® (tests: ADP, ASPI, TRAP) for platelet function testing. The global coagulation was evaluated at pH 6.8 and 7.4 with ROTEM®, which is a rotational thrombelastometry (tests: NATEM and APTEM). The pH levels of the blood samples were achieved by titration of HCl and NaOH.

Results In MEA the AUC was significantly reduced for pH 7.0 and pH 6.8 in all three tests (ADP, ASPI and TRAP), as well as aggregation and velocity. Platelet function was not influenced by alkalosis (pH 7.6). In ROTEM® the AUC, CT, CFT and MCF showed no significant alterations. The α-angle and lysis index for 60 minutes were significantly reduced at pH 6.8. NATEM values were significantly different from those measured with APTEM.

Conclusions In our study we evaluated a significant decrease of platelet function at pH 7.0 and 6.8 with MEA. The results of the analysis with the ROTEM® system showed a significant reduction of thrombus formation at pH 6.8, as described in the literature. In the APTEM test, we could identify hyperfibrinolysis.

Hemostasis system condition in progress of sepsis in severe burns
M Plesyankova, S Evstigneev
Nizhny Novgorod Research Institute of Traumatology and Orthopedics, Nizhny Novgorod, Russia

Introduction Among infectious complications in patients with serious heat injury, the most dangerous is sepsis developing in the early stages of burn disease. Sepsis is characterized by a fulminant, severe course, complex diagnostics, and a high case fatality rate. Hemostasis system disorders are one of the key pathogenic links of organ failure development in sepsis.

Methods The hemostasis system condition was studied in 100 patients with over 20% of the body burned, from the first to 12th day after burn. Examined patients were divided into two groups: in the first group an acute period of burn disease was complicated by progress of sepsis (33 patients), and in the second group complications in the form of sepsis were not observed. The groups of patients studied were balanced in age and severity of the disease. Sepsis was diagnosed on the basis of clinical, laboratory and bacteriological findings, as well as confirmed by morphological studies in casualties. The control group consisted of 130 apparently healthy people.

Results Comparative analysis of hemostasis system disorders in severe burn patients with early sepsis and those without similar complication showed that the progress of generalized infection in the acute period of burn disease is accompanied by reliable decreased activity of antithrombin III, Xlla-dependent fibrinolysis, blood plate count, and prothrombin time prolongation. There were no differences revealed between the studied groups of severe burn when determining fibrinogen content, soluble fibrin monomeric complexes, activated partial thromboplastin time, thrombin clotting time and eichox time, and the test revealing fragmented erythrocytes. Correlation analysis showed that the most contingency between progress of sepsis and hemostasis system data was noted on the third to fourth days after burn (with decreased activity of Xlla-dependent fibrinolysis (r = 0.58, P <0.0001), antithrombin III (r = –0.57, P <0.0001), prothrombin time (r = 0.49, P <0.0001) and thrombocytopenia (r = –0.48, P <0.0001)). On the basis of a retrospective analysis of case histories of severe burns with verified generalized infection, it was determined that the development of an acute form of DIC syndrome manifesting in a marked imbalance of coagulation and antiocoagulative blood mechanisms as well as severe hepatorenal failure has a lead time of 1 to 8 days in revealing sepsis in the clinic.

Conclusions Hemostasis system disorders corresponding to an acute form of DIC syndrome not only accompany the progress of sepsis in severe burn but can be an indirect predictor of its development.

Muscular compartment syndrome and in vivo optical spectroscopy monitoring: a new model
F Ponciani, F Forget, M Vanhoonacker, G Stoquart, T Lejeune, F Lois, D Kahn, M De Kock
UCL, Brussels, Belgium

Introduction The muscular compartment syndrome (MCS) is consecutive to an increase in intramuscular compartment pressures [1],
Introduction Sepsis affects the venous component of microcirculation by decreasing venular compliance and volume of the venular bed. This might be caused by a real decrease of venular bed volume, due to microthrombosis, or by an increase of venular tone. However, the clinical relevance of our findings is not known, and further studies are needed.

Role of microcirculatory monitoring in polytraumatic patients
A Donati, S Loggi, R Domizi, MR Lombrauno, V Fiori, A Valentini, MC Melia, C Scorcella, A Cersetti, P Pelaia
Università Politecnica delle Marche, Ancona, Italy

Introduction Seventy-five percent of ICU mortality after the first 72 hours following major trauma is due to multiple organ dysfunction syndrome (MODS) [1]. How to follow this evolution is not completely understood yet and new parameters are still needed. The aim of this study was to evaluate the effects of polytrauma on sublingual microcirculation and to search correlations among it, Sequential Organ Failure Assessment (SOFA) score and biochemical markers and to use these factors for monitoring patients [2].

Methods This prospective study included 12 patients. Sublingual microcirculation has been registered using sidestream dark field imaging and analysed with AWA software, searching for indices of

This is a rare but serious postoperative complication. In vivo optical spectroscopy (INVOS) monitors tissular oxygenation continuously and non-invasively. Our objective was to develop a model mimicking the physiopathology of MCS and to assess the interest of the INVOS in this case [1-3].

Methods After approval of the ethics committee, we inflated a tourniquet in nine healthy volunteers at a pressure equal to the mean arterial pressure (MAP), obtaining a model of slight venous congestion and arterial hypoperfusion. The INVOS monitoring was compared with sensory deficits, pain, motor activity, electromyography and invasive pressure.

Results A profound motor nerve conduction block (>30% decrease in action potential amplitude from baseline) was observed in the seven volunteers completing the protocol, immediately reversible after releasing the external pressure. At baseline, the values of MAP, INVOS and intracompartmental pressure (ICP) were respectively 94.3 ± 6.5 mmHg, 73.3 ± 8.9% and 16.9 ± 8.6 mmHg. At the time of appearance of a significant block, the values of INVOS were 46.4 ± 10.9%; the absolute decrease of INVOS was 28.7 ± 10.6% and the ICP values were 70.0 ± 5.5 mmHg. The times to reach this significant block from baseline and from the time of an absolute INVOS decrease of 10% were respectively 33.0 ± 10.9 minutes and 27.43 ± 10.4 minutes (Figure 1).

Conclusions Our model is appropriate since it mimics perfectly MCS [3]. The time after achieving an absolute decrease of the INVOS value of 10% from baseline is as accurate as the time of intracompartmental hyperperfusion to predict MCS (Figure 2).

References
vessel density, perfusion and type of flow. For each patient, SOFA parameters, hemocoagulation indices, cytonecrosis criteria and hypoperfusion measures have been evaluated at admission and every 48 hours, for a minimum of 96 hours, and correlation between these and microcirculatory parameters has been researched. We then evaluated the discriminating capacity of these parameters versus microcirculatory indices, calculating the area under the ROC curve.

Results No correlation was found between microcirculatory indices and the others. The following parameters had good discriminating capacity: SOFA-platelets (area = 0.745), total-SOFA (0.724) and D-dimer (0.670) for perfused vessel density (PVD) values; Hb (0.693) and SOFA capacity: SOFA-platelets (area = 0.745), total-SOFA (0.724) and D-dimer and the others. The following parameters had good discriminating microcirculatory indices, calculating the area under the ROC curve.

Conclusions Even in polytrauma, microcirculatory dysfunction is important for MODS appearance, and its analysis (PVD, TVD, De Backer score, MFI) can help to evaluate this evolution, according to biochemical markers and severity index: joined with macrohaemodynamic indices, they allow one to better investigate organ features.

Early trauma deaths in a level 1 trauma center: whole-body CT is associated with a threefold increase in the time interval from hospital access to emergency surgery if compared with a standard protocol

G Nardi, E Cingolani, S Rogante, C Siddi, G Ranaldi, AP Cossu, D Piredda Ospedale S. Camillo-Forlanini, Rome, Italy

Introduction A retrospective analysis based on the data of the German Trauma Registry has shown a significant increase in the probability of survival in polytrauma patients submitted to whole body CT (WBCT). However, even when the CT is installed in the Emergency Department, the time required for positioning the patient for CT may significantly prolong the duration of CT diagnosis.

Methods Our hospital is a level 1 trauma center with a catchment population of 2.5 million; there are two CT scans in the ED. All severely injured patients are submitted to US on admission. WBCT is performed as the first-line radiologic investigation in haemodynamically stable patients or in unstable patients with negative abdominal US and without a clear source of bleeding. Unstable patients with severe head trauma and lateral signs are also submitted to CT. To evaluate whether the use of CT in the severely unstable patients brings a significant delay in emergency surgery, we retrospectively analyzed all early trauma death from January 2009 to November 2010.

Results Seven hundred severe trauma patients (ISS >15) were brought in alive. Thirty-eight (5.4%) died before ICU admission: 21 died in the shock room before any surgical intervention. One patient was submitted to thoracotomy and laparotomy in the shock room and died. One more died on the CT table. The remaining 15 patients, severely hypotensive, were alive on admission to the OR. One of them was brought directly to the OR with no investigation because of massive bleeding from the extremities. The others had US on admission. US was the only investigation for seven of them; they all had a positive US showing important bleeding in the abdomen or in the chest. The other seven, who had no evidence of bleeding on the US, were submitted to WBCT. The mean time elapsed from hospital admission to OR entrance was 23 minutes (15 to 30 minutes) for patients who had only US and 70 minutes (52 to 90 minutes) for the CT group. The seven patients who had only US were all submitted to shock room decompressive minithoracotomy (five bilateral) with the suspicion of pneumothorax.

Conclusions Recent reports suggest implementation of multi-slice CT integrated into the resuscitation room, thus enabling resuscitation to be performed directly on the ER CT. Unless this new technology is adopted, even the ED-based CT still needs excessive time to be performed in most unstable patients. In a cohort of patients who eventually died in the OR, a diagnostic process including ED-based WBCT was associated with a threefold increase in the time needed from hospital admission to surgery.

P452
Diagnostic value of duplex ultrasonography in comparison with conventional angiography in the assessment of traumatic arterial injuries of the extremities

H Ravari
Imamreza, Mashhad, Iran

Introduction Traumatic events are one of the major causes of arterial injuries. Physical examination is not a good predictor of these injuries and arteriography is considered the gold standard for this purpose. In recent years, non-invasive modalities are increasingly replacing diagnostic arteriography. Duplex ultrasonography is an excellent method for investigation of arterial diseases. In this study, we analyze the diagnostic value of duplex ultrasonography in comparison with angiography in traumatic arterial injuries of the extremities.

Methods Duplex ultrasonography was performed for patients with suspicious arterial injury due to extremity trauma just before angiography. The Doppler pattern and flow states were obtained, then standard angiography was performed. The results of duplex ultrasonography were compared with angiography.

Figure 1 (abstract P450). ROC curve: discriminating capacity of D-dimer, SOFA-Plt, and SOFA-tot versus PVD.

Figure 2 (abstract P450). ROC curve: discriminating capacity of myoglobin, lactate and tot-SOFA versus MFI.
Results A total of 75 patients with blunt and penetrating trauma to their extremities were investigated. Duplex ultrasonography had 95% sensitivity and 98% specificity in the diagnosis of arterial injury in this study.

Conclusions We suggest that duplex ultrasonography can be used as a reliable tool, both sensitive and specific, in screening of hemodynamically stable patients with suspicious limb arterial injury.

P453
Simple predictive scoring system for ventilator-associated pneumonia in trauma patients
N Saito, T Yagi, Y Hara, H Matsumoto, K Mashiko
Chiba Hokksu Hospital, Nippon Medical School, Chiba, Japan

Introduction VAP is associated with high mortality in trauma patients. However, detailed data on the prediction of VAP in such patients are limited. We therefore conducted a retrospective study aimed at developing a VAP predictive scoring system for trauma patients.

Methods We retrospectively analyzed 187 consecutive patients with trauma who were ventilated for more than 72 hours between April 2006 and April 2010. VAP was diagnosed by CDC criteria. Patients were divided into the VAP group and non-VAP group and their clinical and laboratory data were compared by univariate analysis using the chi-square and Mann–Whitney U tests. Multivariate analysis using the stepwise method was used to identify predictors of VAP.

Results Victims of blunt trauma accounted for 90.9% of the sample population. The median age of the patients was 50 (32 to 67) years, the median injury severity score (ISS) was 29 (22 to 32), and the hospital mortality rate was 12.3%. Seventy patients were assigned to the VAP group (27/5,1000 mechanical ventilator-days) and 117 to the non-VAP group. The independent predictors for VAP were thoracic cage trauma (odds ratio (OR) 2.5 (P = 0.02; 95% confidence interval (CI): 1.1 to 5.5)), history of chronic heart failure (CHF; OR 8.9 (P < 0.01; 95% CI: 2.4 to 33.0)), chronic obstructive pulmonary disease (COPD; OR 5.9 (<0.01; 95% CI: 1.9 to 18.3)), muscle relaxant (MR) use (OR 5.2 (<0.01; 95% CI: 1.7 to 15.3)), tracheal intubation (TI) in the prehospital setting (OR 4.7 (P < 0.01; 95% CI: 1.8 to 12.4)), use of a nasogastric (NG) tube (OR 6.5 (P <0.01; 95% CI: 2.7 to 15.4)), cervical vertebrae external fixation (CVEF; OR 9.0 (P <0.01; 95% CI: 2.2 to 36.7)), and ISS >25 (OR 5.0 (<0.01; 95% CI: 1.8 to 13.7)). Based on these results, we developed a VAP predictive scoring system. The following simplified clinical risk assessment tool was developed from the results of multivariate analysis, with scoring based on a cut-off point related to the adjusted odds ratio. VAP score: thoracic cage trauma = 2 points, CHF = 8 points, COPD = 5 points, MR use = 5 points, TI in the prehospital setting = 4 points, NG tube = 6 points, CVEF = 9 points, ISS >25 = 5 points. The area under the receiver operating characteristic curve for VAP in this scoring system was 0.847 (P =<0.001; 95% CI: 0.79 to 0.90). The cut-off value for this score according to the sensitivity specificity curve in relation to VAP was 15 points. Sensitivity was determined at 91.1%, and specificity 74.5%.

Conclusions The simple predictive scoring system developed for VAP in trauma will help physicians in the planning of early patient care.

P454
Effect of a trauma proforma on the quality of documentation in the Emergency Department
JE Millar, B Fisher, R McLaughlin
Royal Victoria Hospital, Belfast, UK

Introduction Improvements in trauma care are driven by an understanding of the patient population and their outcome after injury. In order to achieve this, many centres submit data to trauma registries. This process relies on accurate and comprehensive documentation. The aim of this study was to evaluate whether the introduction of a standardised proforma for major trauma patients improved the quality of documentation in an urban Emergency Department (ED).

Methods In September 2010 a proforma was introduced within the ED for use in patients presenting after major trauma. Prior to this, clinical documentation for these patients was recorded on the standard ED record. The last 30 patients attending the ED prior to introduction of the proforma, with major injuries requiring admission to a critical care bed or the operating room, were identified. In addition, 15 completed proformas were available for comparison. In order to set a standard for this comparison, the Utstein template for uniform reporting of data following major trauma [1] was examined to identify core variables that should reasonably be recorded in the ED. Of 31 variables, 23 were felt to be relevant. The ED record or proforma for each patient was then scrutinised in an attempt to extract these variables. A comparison was made between the two groups.

Results In those attending prior to the introduction of a proforma, the mean number of variables identifiable from the clinical record was 12/23 (52%); after the introduction of the proforma this improved to 20/23 (87%). Several parameters were well documented amongst both groups including age, gender and those relating to mechanism of injury (accountable for 5/23 variables). These were identifiable in greater than 95% of cases. Use of the proforma improved the documentation of the remaining 18 variables, including base excess, level of prehospital care and first key emergency intervention. The most marked improvements were seen in the documentation of prehospital observations (GCS, GCS motor component, systolic blood pressure and respiratory rate). Among the pre-proforma group, 0/30 patients had a fully recorded set of prehospital care observations; this improved to 9/15 (60%) in the proforma group.

Conclusions Improvements in trauma care are reliant on our ability to audit current practice, this in turn relies upon robust data collection. In a busy and stressful resuscitation room this is easily over looked. The introduction of standard documentation improves the clinician’s ability to record such information.

Efficiency of a French-language triage algorithm in the Emergency Department
J Jobé1, A Ghysen1, P Gérard2, V D’Orion1
1University Hospital, Liège, Belgium; 2University, Liège, Belgium

Introduction ELISA (Echelle Liégeoisse d’Index de Sévérité à l’Admission) is a valid new Emergency Department (ED) triage algorithm including five levels of categorisation (from U1, high emergency degree, to U5, low degree), based on vital signs and selected anamnestic data. Previous work has demonstrated that ELISA evidenced a strong inter-rater and intra-rater agreement [1]. In this study, we aimed at further evaluating its efficiency.

Methods From March 2008 to May 2008, we prospectively investigated 545 consecutive admissions to study the potential correlation between ELISA score and impact on resource consumption as well as ED stay. Resources were classified following three categories: complementary examinations (ECG, blood analysis, X-ray, and so forth), medical treatments (i.e., medications, casts, sutures, and so forth), and outcome after ED admission (discharge, hospitalisation, ICU admission or death). Each resource was considered a binary variable and was analyzed by means of a likelihood ratio test and correlation analysis. The ELISA score evidences the highest emergency degree.

Results The simple predictive scoring system developed for VAP in trauma will help physicians in the planning of early patient care.
Conclusions In addition to previous work demonstrating a strong inter-rater and intra-rater agreement, the present study points out the potent efficiency of ELISA, allowing its further use in the ED.

Optimized patient transfer using an innovative multidisciplinary assessment in the Kanton Aargau (OPTIMA I): an observational survey in lower respiratory tract infections
F Dusemund1, W Albrich1, K Ruegger1, R Bossart2, K Regez2, U Schild2, A Conca2, P Schuetz3, T Sigrist4, A Huber5, B Reutlinger5, B Muller1
1 Medical University Department of the University of Basel, Kantonsspital Aarau, Switzerland; 2 Department of Nursing, Kantonsspital Aarau, Switzerland; 3 Harvard School of Public Health, Boston, MA, USA; 4 Department of Pneumology, Kantonsspital Zug, Switzerland; 5 Department of Laboratory Medicine, Kantonsspital Aarau, Switzerland

Introduction Current medical scores have limited efficiency and safety to assign the most appropriate treatment site to patients with lower respiratory tract infections (LRTIs) [1-4]. We describe our current triage practice and assessed the potential of a combination of CURB65 with proadrenomedullin (ProADM) levels for triage decisions.

Methods Consecutive patients with LRTIs were prospectively followed and retrospectively classified according to CURB65 and ProADM levels (CURB65-A). Low medical risk patients were further subgrouped according to biopsychosocial and functional risks. We compared proportions of patients virtually allocated to triage sites with actual triage decisions and assessed the added impact of ProADM in a subgroup.

Results Ninety-six percent of 253 patients were hospitalized. Among the 136 patients with available CURB65-A, 17.4% had low medical risk indicating possible treatment in an outpatient or nonacute medical setting: 34.1% had intermediate medical risk (short hospitalization); and 48.6% had high medical risk (hospitalization). Fewer patients were in a low CURB65-A class (I) than a low CURB65 class (0, 1) (17.4% vs. 44.6%, P < 0.001). Mean length of hospitalization was 9.4 days including 3.5 days after reaching medical stability. In 56.9% of patients, hospitalization was prolonged after medical stability mainly for medical reasons.

Conclusions Current rates of hospitalization are high in patients with LRTI and the length of stay frequently extended beyond time of medical stabilization. The lower proportion of patients reclassified as low risk by adding ProADM to the CURB65 score might improve confidence in the triage algorithm.

Agreement of pain assessment between nurses and patients in the Emergency Department
M Modanlo1, H Abdollahi1, N Behnampour2
1 Golestan University of Medical Sciences, Gorgan, Iran

Introduction Pain is one of the most common reasons why patients visit the Emergency Department (ED) and is a healthcare problem for patients [1,2]. The purpose of this study was to determine the agreement between patient self-reported pain intensity and nurse pain assessment in the ED.

Methods A purposive sample of 100 patients and 36 nurses in the triage and clinical area within the ED was selected from 5Azar Hospital in Gorgan. The questionnaire included two components: participant characteristics and the Numeric Rating Scale (NRS). A questionnaire was administered twice to each patient. In triage the patients were asked to rate their pain intensity. Separately, the nurses assessed the patient's pain intensity. This process was repeated with the same patients after referring them to a clinical area within the ED, but the nurses were different. Gathered data were described by frequency distribution tables and analyzed by Wilcoxon, Mann–Whitney and Spearman tests. P < 0.05 was considered significant.

Results Most of the patients were male (61%), with mean age of 39.16 ± 16.83 years. Fifty-four percent of the patients had chronic pain. Most of them had a diagnosis of abdominal pain and chest pain (61%). In the triage, the mean nurses’ pain intensity score was significantly lower than patients’ score (7.60 ± 2.1 vs. 9.13 ± 1.26), as significant differences in mean scores were observed (P < 0.001). In the clinical area, patients’ scores were also significantly higher than nurses 7.36 ± 2.56 and 5.94 ± 2.33, respectively (P < 0.001). Nurses significantly underestimated pain on the NRS. See Table 1.

Table 1 (abstract P457). Patients’ (n = 100) and nurses’ (n = 36) pain intensity scores

Data presented as mean (SD).

Conclusions The findings have implications for the management of patients’ pain by highlighting the need for more accurate pain assessment. Further research is required to elucidate the way in which nurses and patients conceptualize pain and to understand better the process of pain assessment in clinical nursing practice.

Effect of delayed ICU admission on mortality and morbidity
R Ramaiah1, B Shepard2, P Hopkins2, R Maharaj1
1 King’s College Hospital, London, UK

Introduction Delayed admissions to the ICU from the Emergency Department (ED) may be associated with increase in mortality and morbidity [1]. We wanted to answer the following questions: is there an association between the timing of presentation to the ED and mortality; and is the time interval between the patient presenting to the ED and admission to the ICU associated with increase in mortality and morbidity?

Methods We collected the number of patients admitted from the ED to the ICU from April 2009 to March 2010. The time duration from the patient presenting to the ED and the patient admitted to the ICU was selected from 5Azar Hospital as delayed admission, as per the national standards. We assessed the APACHE score of the patient on admission, the length of stay in the ICU (LOS), relationship to the time of ED admission (either office hours 08:00 to 17:00 or out of hours 17:01 to 07:59) and the hospital mortality associated with each admission.

Results We had 547 admissions to the ICU from the ED. There was no significant association between out of office admission to the ED and hospital mortality (OR = 0.858, 95% CI = 0.457 to 1.610) after adjustment for age and APACHE score. There was also no statistically significant difference between patients that took more than 4 hours between ED and ICU, with respect to the hospital mortality (OR = 1.00 and 95% CI = 0.999 to 1.001). We performed a COX regression analysis to establish whether delays were associated with increased LOS, using age and APACHE as the covariates. There was no statistically significant association.
between ICU LOS and delays to ICU admission (hazard ratio = 0.948 and 95% CI = 0.934 to 0.962). There was no difference between APACHE scores >25 and ICU admission delays (chi-square \( P = 0.897 \)).

**Conclusions**
There was no association between delay in ED to ICU admission on mortality or length of stay in the hospital. This might be due to the fact that the sick patients presenting in the ED are seen by a physician early, thereby leading to appropriate triage of the patient to the ICU. APACHE II scoring seems to be an independent variable and has a linear relation to the mortality and length of stay in the hospital.

**Case note and chart review of mortality in patients with a predicted low risk of death on admission to the ICU**

S Elia, R Fisher, M Mostert
University Hospital Lewisham, London, UK

**Introduction**
The aim was to establish whether suboptimal care or system failures in the delivery of care contributed to mortality in patients admitted with a predicted low risk of death to our ICU.

**Methods**
We defined low risk of death as a predicted mortality of less than 20% based on either the ICNARC or APACHE II risk prediction models [1]. We reviewed the case notes and ICU charts of patients with a low risk of death admitted to our ICU during July to December 2008 and April to September 2009.

**Results**
Seven hundred and fifty patients (799 admissions, 49 readmissions) were admitted during the periods under review. The hospital mortality rate was 20.7% (155 patients) and of the 155 nonsurvivors 29 patients had a predicted low risk of death. Case notes for five patients could not be obtained and notes and charts for 24 of the 29 patients were reviewed. Errors identified in data collection: in two patients, incorrect data collection was identified that may have underestimated the risk of death. Suboptimal care identified: in four patients (16.7%), five instances of suboptimal care or system failures in care delivery were identified – delay in obtaining investigations (one laboratory, one radiology) delayed definitive treatment (two cases), delay in referring patient to the ICU (one case), elective surgical procedure caused bowel injury in a high-risk patient (one case), and delay in obtaining medical records caused the inappropriate admission of a patient to the ICU (one case). Patients with severe progressive illness: some patients were admitted with a low physiology score and low predicted risk of death but with a poor prognosis due to an underlying progressively ill illness.

**Conclusions**
A case note review of ICU nonsurvivors can identify areas where service delivery and patient safety can be improved. Four patients (16.7%) with alcoholic liver disease (ALD) died despite a low physiology score on admission. The increased incidence of ALD in our unit is in line with the national trend.

**Cost impact of blocking: predictability of ICU patient throughput and cost variance using process modelling**

S Nabors 1, T Boumontreil 1, S Schaefer 1, L Luangkesorn 1, J Khouroufeh 1, L Mailart 1, W Yang 2, G Clermont 1

1University of Pittsburgh Medical Center, Pittsburgh, PA, USA; 2University of Pittsburgh, Pittsburgh, PA, USA

**Introduction**
Efficient management of ICU patient turnover can significantly impact patient survival, medical expenses, overall satisfaction, and hospital operating expenses. Movement within a constrained healthcare delivery system is a dynamic and stochastic process that eludes traditional analysis and prediction tools. We hypothesized that simulation-based approaches allow for a better capture of the interaction between reality and policy, and therefore guide efficient ICU management. We developed a simulation process, modeling constrained hospital patient flow in a tertiary care center and generated a cost-variance analysis derived from differences in that patient flow.

**Methods**
This study consists of a retrospective analysis of a comprehensive sample of 3,518 patients admitted to the VA Pittsburgh Health System from 27 April 2010 to 3 November 2010. Patient movement data are extracted to produce a cohort dataset and time-series analysis of patients transitioning in the following units: the medical ICU (nine beds), surgical ICU (11 bed), coronary care unit (18 beds), step-down unit (nine beds), monitored medical (15 beds), monitored surgical (12 beds), nonmonitored medical (44 beds) and surgical (19 beds). Cost data are extracted from the VAPHS annual budget review and cost allocation records for specific patient units and levels of care. Blocking time is the difference between time of assignment and movement to a specified location. Assignment difference is the probability of being assigned to a location other than requested location. Cost variance is the difference between cost allocations based on standardized clinically indicated LOS and the cost allocations based on real LOS averaged per unit location.

**Results**
This model graphically depicts LOS rates, blocking times, assignment difference rates, and cost variance. The worst blocking time is observed for monitored medical beds (44 hours) while the worst assignment difference is observed for surgical monitored beds (0.55). The worst cost variance is recorded in the surgical ICU ($572,000). The total cost variance is $849,000.

**Conclusions**
ICU flow is a dynamic process affected by constraints manifesting in large blocking times, assignment differences and significant cost variance. This novel flow management tool could systematically and objectively aid managerial decision-making at both the unit and hospital levels.

**ICU readmission: good or bad?**

E Potter, D Vondra, S Green, M Zuleika
Royal Surrey County Hospital, Guildford, UK

**Introduction**
Patients requiring ICU management risk deterioration following discharge. Readmission to the ICU is used as a marker of performance [1] with some controversy [2]. It is established that higher APACHE II scores and longer length of ICU stay are associated with higher risk of ICU readmission [3]. However, there are no criteria available to identify those patients most likely to benefit from readmission [4].

**Methods**
Prospective data were collected on all patients admitted to a multidisciplinary adult ICU between 2001 and 2009 and entered into a computerised database. This included length of ICU stay, ICU and hospital outcomes, readmission to ICU and days prior to readmission. Data for all ICU admissions were analysed annually.

**Results**
There were 5,004 patients admitted during 2001 to 2009; 1,315 (26%) were elective postoperative admissions and 3,689 (74%) emergency admissions. The ICU mortality during this period was 15.8% and mean APACHE II score was 7.7 (1 to 55). There were 299 readmissions (6%). The average time between discharge and readmission was 8.5 days (0 to 89) with a mean length of ICU stay of 5.89 days (0.2 to 48.8). The average hospital mortality rate of readmitted patients was 33% and fell from 69% in 2003 to 24% in 2007. The proportion of readmitted patients increased from 3% (11) in 2001 to 10% (68) in 2007. As the proportion of patients readmitted increased, the hospital mortality rates for all ICU admissions fell 10% from 31% in 2001 to 21% in 2009.

**Conclusions**
As the number of patients readmitted has increased, hospital mortality of both readmitted patients and total ICU patients have fallen. Those readmitted have had a short length of stay (mean 5.89 days).

Is the ASA physical status classification system a good prognostic index for ICU admissions?

A Gregorio, A Pais-de-Lacerda, C França
Hospital de Santa Maria, Lisbon, Portugal

Introduction The physical state of the patient before surgery is defined by the American Society Anesthesiology (ASA) physical status classification system. The Simplified Acute Physiology Score (SAPS II) provides an estimate for the risk of intrahospital death for ICU patients. The Sequential Organ Failure Assessment (SOFA) score is used to monitor the patient’s condition during his/her stay in the ICU, assessing the extent of organ dysfunction or failure. Is the ASA physical status classification system a good prognostic index for determining postsurgical patient’s admittance to the ICU? What is the evolution of these patients? Could we predict the outcome of these patients?

Methods A retrospective analysis of the ASA, SAPS II and SOFA of all postsurgical patients admitted to an ICU, between 1 May and 31 October 2010.

Results Total ICU admissions: 323 patients, 118 being postsurgical patients (mortality: 12 patients – 10.17%). Maximum patient ASA: between 0 and 19. Patient SAPS II: between 8 and 99. Of the 118 patients, five had ASA 5, a mortality of 100% being expected but only three died. The expected mortality rate of the three deceased (SAPS II: 58, 99, 80) was 5.2%, 92.5%, 98.4%, respectively. The two patients who got better had a SAPS II of 21 and 56 with a maximum SOFA of 4 and 16, which means that they improved significantly, against all odds. Most ICU admitted patients were ASA 3 and ASA 4. Fifty per cent of ASA 3 patients presented a maximum SOFA between 0 and 5; maximum SOFA was higher in 34% of ASA 3 patients (5 to 10) with predicted ICU mortalities of up to 7% and 46%, respectively. Four patients of the ASA 3 group died. Of the ASA 4 patients, 43% had a maximum SOFA between 5 and 10, and 34% presented a lower maximum SOFA (0 to 5). In 10 (26%) ASA 4 patients, maximum SOFA exceeded 11 with a mortality ICU predicted rate of 56%. In fact, five died. The reason for admission to the ICU of the 20 patients with lower ASA (17 ASA 2 patients, three ASA 1 patients) was a need for tighter monitoring or stabilization of postsurgical complications. Indeed, all deaths in the ASA 2 (1/17) and ASA 3 (4/38) groups were related to complications from co-morbidities. Conclusions ASA 3 and ASA 4 patients are those who benefit the most from a stay in an ICU, enabling one to reduce mortality predicted by SAPS II and SOFA scores. The ASA physical status classification system is not a good indicator of mortality, but its association with SAPS II and maximum SOFA scores define more effectively the severity and prognosis of the postsurgical patient.

Factors and consequences associated with a delay in the discharge process of patients from an adult critical care unit

J Mellinghoff, A Rhodes, M Grounds
St George’s Healthcare NHS Trust, London, UK

Introduction Adult intensive care beds are a scarce and expensive resource. Efficient utilisation of these beds necessitates safe and timely discharge of patients to the general ward. However, the discharge process is complex and often delayed. This study aimed to look at the processes and consequences that cause a delay in the discharge of patients from an adult ICU.

Methods This was a retrospective study of our data collection databases based in a 17-bed London teaching hospital ICU. We examined the process of patient discharge from ICU to the ward over a 3-year period.

Results The study period was from July 2007 until June 2010. There were 3,511 patient discharge episodes to hospital wards. A delay of over 4 hours occurred in 2,829 patient episodes (81%). The delays in discharge to the wards increased by over 100% for the year following a reduction of 28 beds in total intrahospital ward bed capacity [1]. There were over 42,000 hours (equal to 1,751 days) of delays in discharges for the patient episodes. Delays were caused by all stakeholders involved in the discharge process. The main reasons were insufficient ward bed availability (21%), delays in bed allocation (30%), delays in the completion of administrative tasks on the ICU (4%), delays in adequate preparation of ward beds (27%) for the arrival of the ICU patient, and delays that were attributable to intrahospital transport arrangements (5%). Overall, discharge delays to surgical wards were twice as likely compared with medical wards as they were also trying to deal with elective and emergency surgical admissions. Medical wards had fewer delays in transfer but were more likely to have longer delay times as a result of subsequent delays in discharging patients back to the community.

Conclusions Delays were multifactorial and accumulative in nature and dependent on the individual processes involved in the transfer of patients. Themes were related to organisational, individual, teamwork and patient factors.

Intensive care admission triage for a pandemic: are government tools acceptable to UK intensivists?

DT Ashton-Cleary, NV Freeman, A Tilley

Introduction Triage criteria recommended by various governmental bodies are part of a process to cope with increased demand for intensive care resources during a pandemic [1]. It is unknown whether UK intensive care physicians agree with the proposed criteria that could automatically exclude a patient from receiving ICU care if adopted.

Methods We conducted an online survey amongst the members of the UK Intensive Care Society. We asked respondents to grade their opinion about each criterion of a Department of Health (DoH) triage tool and provide some additional information about their own health. We used Cronbach’s alpha (CA) to assess how close the opinions of the respondents were with regard to each criterion and each of three sets of criteria. We used a chi-squared analysis to see whether these factors differed between intensive care consultants and nonconsultants.

Results A total of 550 questionnaires were returned; 182 (33.1%) were from intensive care consultants. For six of the DoH 11 criteria, the agreement score was >4/5 indicating agreement or strong agreement. For both consultants and nonconsultants, the CA was >0.8 (significant inter- responder agreement). A total 19.4% of those currently meeting exclusion criteria and 34.6% of those in good health would give up the chance of a level 3 bed voluntarily if they fulfilled one of the proposed criteria during a pandemic.

Conclusions The results indicate a general acceptance of the requirement for triage but nearly 40% have significant reservations about the proposed tool. Sixty-five to 80% of respondents would not withdraw from the triage process in a pandemic even if they knew the proposed criteria would exclude them. While approximately 60% of respondents accepted the triage tool, it seems the majority would not wish it to be used to determine their own care.

Length of hospital stay prior to ICU admission and outcome

K Simpson, G Williams, T Quasim

Glasgow Royal Infirmary, Glasgow, UK

Introduction We hypothesised that for the general ICU population, a longer length of hospital stay prior to ICU admission was associated with a poor outcome. Previous work in specific ICU populations has suggested that an association of length of hospital stay prior to ICU admission is associated with a higher mortality [1,2], and longer and therefore more costly ICU stays [3]. We undertook an evaluation of the relationship between pre-ICU length of hospital stay (LOS), and hospital mortality over a 1-year period.

Methods Using prospectively collected data, we undertook a retrospective evaluation of all patients admitted to the ICU of Glasgow Royal Infirmary from 1 August 2008 to 1 August 2009. Patients were identified from Wardwatcher (Critical Care Audit Ltd). Only the initial event was included in those patients with readmissions during the same hospital stay. The patients were divided into hospital survivors (Group A) and nonsurvivors (Group B). Statistical analysis was performed using SPSS version 15.0 for Windows (SPSS Inc, Chicago, IL, USA). Medians, interquartile ranges (IQRs) and Mann–Whitney U tests were applied as appropriate.

Results A total of 419 patients were admitted during the study period. After excluding those with missing data and the outliers, 397 were included in the data analysis. There were 268 in the survivor group (Group A), and 129 in the group that died (Group B). Median patient age: Group A, 50 (IQR 36 to 66), Group B, 62 (IQR 50 to 70), P <0.001. Median APACHE II scores: Group A, 15.9 (IQR 6.3 to 31.6), Group B, 46.8 (IQR 30.8 to 67.4), P <0.001. Median predicted hospital mortality (%): Group A, 15.9 (IQR 6.3 to 31.6), Group B, 46.8 (IQR 30.8 to 67.4), P <0.001. Median pre-ICU LOS (days): Group A, 1 (IQR 0 to 2), Group B, 1 (IQR 0 to 4), P =0.001. Median ICU LOS (days): Group A, 2 (IQR 1 to 6), Group B, 2 (IQR 1 to 7), P =0.297. Median hospital LOS (days): Group A, 18 (IQR 7 to 36), Group B, 8 (IQR 3 to 23), P <0.001.

Conclusions In our cohort, the critically ill patients who survived to hospital discharge were younger, were less severely unwell and had a significantly shorter length of stay prior to ICU admission. What cannot be determined from this study is the bias of individual clinicians when seeing referrals. Assuming we admit the patients we anticipate to have the best chance of hospital survival, patients with a longer length of hospital stay prior to ICU appear to have worse outcomes.

Patients’ profile admitted to the ICU after establishment of a regulatory policy system for ICU patient allocation at public hospitals in Rio de Janeiro, Brazil

R Goldwasser1, S Oliveira1, C David1, M Oliveira1, A Babo1

1Secretaria Estadual de Saude, Rio de Janeiro, Brazil; UFRJ, Rio de Janeiro, Brazil

Introduction The consolidation of intensive care fundamentals was accompanied by growth of ICUs and increased utilization of intensive care services. Unfortunately it was not followed by national health planning. The demographic changing profile with a higher number of elderly patients and a changing case mix with less trauma patient admissions, associated with the high prevalence of cardiovascular diseases and the early approach to septic patients, will have implications on intensive care organization. A regulatory policy system for public ICUs was started in Rio de Janeiro to ensure appropriate selection and allocation of patients who need intensive care. The aim of this study is to report the profile of patients admitted to the ICU since the beginning of this new policy.

Methods A retrospective, 1-year, analysis of data from the Regulation Center. A nonchecklist medical application form is transmitted by fax for ICU patient allocation. Requests originated both from the hospital emergency room (HER) and nonhospital emergency units of care (Unidade de Pronto Atendimento (UPA)). The age, gender and the main prevalent diseases were recorded. Acute cerebrovascular disease (CVD) was considered all forms of stroke, both ischemic and hemorrhagic injuries; acute coronary disease (ACD) was considered stable and unstable angina and acute myocardial infarction; sepsis for severe sepsis and septic shock; trauma for any severe trauma, multiple trauma, burns and brain trauma; pneumonia for any severe lung infection with or without respiratory failure; and cardiac failure for any severe heart failure and acute pulmonary edema due to cardiac disease.

Results There were 15,036 applications, 10,360 (68.9%) forms from HER and 4,676 (31.1%) forms from UPA. From 12,591 adult requests, 7,333 were men and 5,258 were women. Mean age was 61.54 years old, and 461 (4%) were >80 years old. Major diseases that motivated the requests for admission were ACD (1,871, 15%), CVD (1,753, 14%), pneumonia with or without organ failure (1,678, 13%), sepsis (1,423, 11%), cardiac failure (825, 7%), trauma (741, 6%) and others (4,300, 3%).

Conclusions There was a significant number of ICU requests, mainly from in-hospital demand. The discussion regarding the indication of ICU care and knowledge of the patient profile may improve quality of the health critical care policy.

Changes in very older person admissions to an ICU over a decade

J Connelly, E Dawe, H Jones

Morriston Hospital, Swansea, UK

Introduction The UK population is getting older and consequently our attitudes, together with the number of very older person admissions
to critical care, may be changing [1]. We therefore reviewed admissions aged 80 or over (very older people) to our ICU and compared this with 10 years ago.

Methods Retrospective data collection was completed for all patients admitted to our ICU for a 12-month period starting in August 2009, and a comparable 12-month period starting August 1999. Data were retrieved from an electronic database of ICU admissions.

Results The number of very older patients admitted for the 1999 period was 87 out of a total 702 (12.4%) and for the 2009 period was 156 out of a total 1,071 (14.6%). There was a marked increase in emergency medical (from 24% to 47%) and emergency surgical (from 31% to 41%) admissions in the 10 years. This was in contrast to elective surgical admissions, which have reduced from 42% to 12%. The mean ICU admission APACHE II score for patients over 80 years old decreased from 21.2 to 18.6. The ICU and hospital mortality for the very older people is summarised in Table 1. The ICU mortality for this age group increased from 29% to 33% but the hospital mortality was unchanged at 44%.

Conclusions Changes in population demographics are reflected in our critical care by an increase in the number of very older person admissions. The ICU mortality was higher in this group compared with 10 years ago. One possible explanation is the marked increase in emergency admissions. This may reflect an increased willingness to refer the very older patient for critical care support.

Model Team in the ICU: does the implementation of intensive care assistants affect ICU nursing activity?
KB Tang
North District Hospital, Hong Kong

Introduction The healthcare workforce shortage is a global phenomenon, especially in the ICU. Use of a register nurse–unlicensed assistive personal model is an undeniable reality that fills the void created. Model Team is a structured training program for healthcare assistants to expand their role, facilitating them to perform nursing tasks that require nursing skill and knowledge. The purpose of the study is to investigate whether the Model Team approach could reduce bedside nursing activities.

Methods This was a prospective cohort study. All bedside nurses working in an ICU were recruited. Intensive care assistants have undergone 3-month structured training for specific nursing skills, and then served four ICU beds under the supervision of a bedside nurse. Activities of all involved nurses were recorded before and after the implementation of an intensive care assistant service using the work-sampling method. Activities were categorized into six groups: patient care activities consigned to TISS-28; patient care activities not indicated in TISS-28; patient care activities that are not interventions in direct contact with the patient; organizational activities; personal activities; and miscellaneous activities [1]. The TISS-28 score of each patient was recorded during both sampling periods, serving as an indicator for complexity of nursing activity. A statistical test was performed to compare the frequency of patient care activities related to TISS-28 score (Question A) and nursing activities not related to direct patient contact (Questions C, D, E and F), before and after the Model Team approach.

Results In total 29 nurses were recruited, 14 nurses during the control period and 15 nurses after the Model Team approach. Patients in both periods were comparable with no significant difference in TISS-28 score. Patient care activities related to TISS-28 score reduced by 16.33% (mean frequency 3.43 to 2.87, P = 0.249) after the implementation of the intensive care assistant, but were not statistically significant. For nursing activities not related to bedside care, there was an insignificant increase of 1.67% (mean frequency 4.79 to 4.87, P = 0.448).

Conclusions The Model Team approach may reduce bedside nursing activities, without effect on nonbedside nursing activities. Further study with a larger sample size should be done to test the hypothesis.

The CCT had been activated by each member of the team if needed and had provided rapid medical services including consultation. We evaluated the impact of implementing the CCT on open general ICU patient outcomes.

Methods We performed a prospective observational study in an open general ICU between March 2009 and February 2010 according to CCT. We compared outcome parameters: compliance with patient. Triggering progressed through involvement of junior medical staff at step 3. Outcome parameters: compliance with patient. Outcome through earlier identification of sick patients. We set out to improve outcome of patients admitted to ICU.

Results We analyzed 857 patients’ data (161 cases in CCT vs. 696 cases in non-CCT), excluding readmission cases. Patients who received CCT management were more severe than those who received non-CCT management significantly (APACHE II 21.4 vs. 17.7; SOFA 5.8 vs. 4.9). Although there were more patients on applied mechanical ventilation (46% vs. 23.6%) in CCT than those in non-CCT and a higher success rate of weaning (60.8% vs. 43.9%) in CCT than those in non-CCT, there was no significant difference of unadjusted ICU mortality rates in both groups (14.3% in CCT vs. 12.2% in non-CCT). Using a multivariate logistic regression model, the ICU mortality rate was associated with non-CCT, APACHE II scores, SOFA scores, and applied mechanical ventilation (Table 1).

Conclusions Although the CCT was not a full-time coverage team in the open general ICU, the CCT model was associated with reduced ICU mortality, especially in patients who received mechanical ventilation.

Impact of increased numbers of intensive care consultants on outcome in a central London teaching hospital

M Warach, J Zwaal, M Johnson
Kingston Hospital, Kingston Upon Thames, UK

Introduction The introduction of track and trigger systems for surrogates affecting ICU mortality, especially in patients who received mechanical ventilation.

Methods We performed a prospective observational study in an open general ICU between March 2009 and February 2010 according to CCT. We compared outcome parameters: compliance with patient. Triggering progressed through involvement of junior medical staff at step 3. Outcome parameters: compliance with patient. Outcome through earlier identification of sick patients. We set out to improve outcome of patients admitted to ICU.

Results We analyzed 857 patients’ data (161 cases in CCT vs. 696 cases in non-CCT), excluding readmission cases. Patients who received CCT management were more severe than those who received non-CCT management significantly (APACHE II 21.4 vs. 17.7; SOFA 5.8 vs. 4.9). Although there were more patients on applied mechanical ventilation (46% vs. 23.6%) in CCT than those in non-CCT and a higher success rate of weaning (60.8% vs. 43.9%) in CCT than those in non-CCT, there was no significant difference of unadjusted ICU mortality rates in both groups (14.3% in CCT vs. 12.2% in non-CCT). Using a multivariate logistic regression model, the ICU mortality rate was associated with non-CCT, APACHE II scores, SOFA scores, and applied mechanical ventilation (Table 1).

Conclusions Although the CCT was not a full-time coverage team in the open general ICU, the CCT model was associated with reduced ICU mortality, especially in patients who received mechanical ventilation.

Impact of increased numbers of intensive care consultants on outcome in a central London teaching hospital

V Metaux, C Bell, A Feehan, K Peters, T Chang, P Hopkins, M Ervine
King's College Hospital, London, UK

Introduction The standardised mortality ratio (SMR) is a key parameter by which ICUs quantify their performance. We report the effect of increased ICU consultant numbers on mortality and SMR in a central London teaching hospital.

Methods The study was registered with the Clinical Audit Support System. Data were collected prospectively from March 2005 to date by a dedicated audit team and were analysed as part of routine audit.

Results Table 1 shows the reduction in mortality and SMR from 2005 to date, comparing these data with patient and consultant numbers.

Conclusions In this study we describe the remarkable reduction in both mortality and SMR that has occurred in the general ICU at King’s College Hospital over the past 5 years. The improvement in outcomes was associated with a quadrupling of ICU consultant numbers. We hypothesize that this increase in intensivist numbers allowed the reinforcement of a closed model of ICU care. We are now further analysing these data to search for quantitative improvements in surrogate markers of quality of care over the same time frame.

Intensivist-led on-call service: key step in mortality reduction

NJ Harris, H Kliner, A Krishnamurthy, P Bishop
The Princess Alexandra Hospital NHS Trust, Harlow, UK

Introduction We conducted an audit to determine whether a change to a dedicated intensivist rota in our district general hospital ICU improved patient outcome. Our unit, like many others around the
country, had historically been covered out of hours by anaesthetists rather than specialists in intensive care medicine. This audit therefore had potentially far-reaching implications for many other similar ICUs in the UK.

Methods We conducted a retrospective analysis on data obtained from the ICNARC database, patient notes, drug charts and ICU charts over two cycles. The first ran from 1 December 2008 to 31 January 2009, when the conventional on-call consultant rota was still in operation. The second ran from 1 January 2010 to 31 March 2010, following implantation of a dedicated intensivist rota. Our primary outcome measure was unit mortality. We analysed a further eight parameters as indirect markers of good clinical practice. These were tidal volume, urine output, glycaemic control, lactate, mixed venous oxygen, and appropriate prescription of gastric protection, antibiotics and venous thromboembolism prophylaxis.

Results Patient demographics were similar between the two cohorts under investigation, but the mean admission APACHE II score was found to be significantly lower following the rota change, as shown in Table 1. This reduced inpatient unit mortality from 39% in cycle 1 to 25% in cycle 2. However, the change to an intensivist rota made little difference to our markers of good clinical practice.

Conclusions Our study suggests that the improvement to unit mortality was secondary to patient selection, rather than a fundamental change in clinical practice within the ICU. This indicates that a dedicated rota, in which consultative intensivists lead on out-of-hours referrals, reduces the number of inappropriate admissions to the ICU.

Mews Anesthesia Team: a project for in-hospital patient safety
R Oggiioni, L Tadini Buoninsegni, G Iannello, C Rosati
Azienda Sanitaria Firenze, Borgo San Lorenzo, Italy

Introduction In past years, to improve in-hospital patient safety, rapid response teams were put in place to treat, on ward’s call, the patients at risk in order of their severity.

Methods In the Azienda Sanitaria Firenze, a dedicated group of intensivists and nurses developed a project called the Mews Anesthesia Team (MAT) in order to prevent and manage clinical deterioration of patients. This would be achieved through the activation of a rapid response team lead by an intensivist acting in accordance with an intervention flowchart. The project was based on the Modified Early Warning Score (MEWS), a validated warning score designed to alert ward nurses to patients at risk (MEWS >3) and/or to trigger MAT intervention (MEWS >5). Previously the group realized a pilot phase involving 420 patients, preceded by a 1-day dedicated course addressed to ward staff; the preliminary results showed in 12% of patients with MEWS >3, that sicker patients were located more in surgical wards than in medicine wards (MEWS >3; 22% vs. 7%). As a result of MAT intervention, 30% of patients were admitted to the ICU (mostly from surgery).

Conclusions MAT is ongoing with good acceptance from nurses and good compliance, especially in surgery wards; the inclusion of MEWS into the EHR turned out to be a great support for the nurses. MAT represents a safety system for in-hospital patients at risk, as advocated also by the Tuscany Health Agency for Quality that, in the aim of developing good practices for patient safety, recommends MEWS for tracking and managing critical in-hospital patients.

Conclusions Implementation of a RRS can decrease the number of in-hospital cardiac arrests dramatically and thus avoid (serious) adverse events and possible deaths. Possible success factors include: timely activation of the RRS, the degree of implementation of the R5S, and timely agreed restrictive measurements on the general ward.

P477
Impact of training in the use of an early warning system on in-hospital cardiac arrests
A Raj, J Zwaal
Kingston Hospital NHS Trust, Kingston upon Thames, UK

Introduction The introduction of an early warning system (EWS) has been associated with a reduction in in-hospital cardiac arrest (CA) [1]. We set out to determine the impact of a programme of training in the use of an EWS on the number and nature of CAs in our hospital.

Methods We conducted a retrospective chart survey of all adult CA patients pre and post implementation of a training programme in the use of the EWS. If a patient develops abnormalities in two or more physiological parameters, the system forces escalation of care through three levels of care, with involvement of junior medical staff...
at level 1 and senior ICU medical staff at level 3. Abnormal physiology was defined as: $\text{SaO}_2 < 90\%$, HR < 50 or ≥110/minute, systolic blood pressure < 90 mmHg, conscious level: only responsive to pain, respiratory rate < 10 or ≥25/minute or clinical concern about the patient. Outcome parameters: CA/1,000 bed-days, percentage of CPR attempts deemed inappropriate by two senior intensivists, percentage of patients (in whom CPR attempts were deemed appropriate) with abnormal physiology prior to CA and survival post CA. Charlson’s co-morbidity index (CCI) [2] was calculated for both periods. Differences between mean values were tested with Student’s t-test and differences between percentages were tested according to the method described by Armitage [3].

Results After adjusting for age (mean pre: 81.7, post: 81.8 years ($P = 0.99$)), sex and co-morbidity (CCI pre: 6.4, post: 6.66 ($P = 0.79$)); CA/1,000 bed-days pre: 0.89, post: 0.76 ($P = 0.24$); percentage of inappropriate CPR attempts pre: 62.5%, post: 33% ($P = 0.11$); percentage of cases with abnormal physiology identified prior to arrest pre: 68.8%, post: 75% ($P = 0.72$); and survival pre: 12.5%, post: 0% ($P = 0.20$).

Conclusions Training in EWS was associated with a reduction in the number of CAs and percentage of inappropriate CPR attempts, both of which are in keeping with the literature. However, there was no significant difference in the percentage of cases with abnormal physiology identified prior to CA between both periods and there was no survival benefit after CA. An early warning tool may be unable to prevent CA in a subset of patients with deranged physiology.

Daily physiological goal-setting: medical prescription and nursing adherence in a London teaching hospital ICU
MK Khan, S Alawad, M Thavasothy
Royal London Hospital, London, UK

Introduction Individual, clearly defined physiological goal-setting can help to optimize patient care [1]. At our ICU, eight physiological goals can be prescribed on the daily ICU observation chart. These include Hb, MAP, ICP, CPP, $p_O_2$, $p_CO_2$, fluid balance and sedation scores. We performed a prospective audit assessing doctors’ compliance with goal-setting, nursing adherence to these, and what goals nurses used when none were documented.

Methods An audit was carried out from December 2009 to March 2010. A total of 90 patients were reviewed at random. Data collected included the total number of goals specified by the ICU medical team, the percentage of time those goals were achieved and what goals nurses used when none were documented.

Results Goals were prescribed for only 53% of patients. Most commonly prescribed were CPP targets for 63% of those with ICP bolts. The remaining parameters were prescribed for between 17 and 38% of patients, with balance and sedation goals being least commonly specified. For the ARDS subgroup of patients, no fluid balance goals were documented. Certain patterns were also evident; for example, $p_CO_2$ goal was more commonly stipulated for patients in the neuro group (for 41% of the group). However, there was no pattern seen in the number of goals specified per patient or according to the length of patient stay on the ICU. When goals were set, all targets were met 62% of the time, with >80% of targets met 79% of the time. When goals were not documented, however, 46% ($p_CO_2$) to 78% (fluid balance) of nursing staff were unable to specify what range of parameters they aimed to keep within. The remainder that did aim for particular target ranges stated they were aiming for physiologically normal parameters. Whilst sensible, this may not have been appropriate for some patients.

Results A program was written in Cerner Command Language to automatically search data within the EMR for the most recent values of the following data: ventilation mode, respiratory rate, tidal volume, ideal body weight, administration of any sedative infusion, analgesic infusion, neuromuscular blocking agent, stress ulcer prophylaxis, DVT prophylaxis and regular diet, enteral nutrition, or total parenteral nutrition. Nursing documents oral decontamination, head-of-bed elevation, and whether a sedation vacation was conducted. A customized document was created to capture any patient/family/proxy discussions about end-of-life issues. High and low glucose values and the percentage of all glucose values within the range of 60 to 180 mg/dl are also reported. A summary score was calculated by subtracting (from a baseline of 9) one point each for inappropriate tidal volume, failure to do a weaning trial, lack of oral care, head-of-bed elevation and stress prophylaxis, no sedation vacation and absent DVT prophylaxis, absent nutritional support or glucose values out of range. A perfect score is 9; lower scores indicate an opportunity for improvement. Clinicians access the report from within the hospitals EMR and can view it on a portable device (iPad) or print it to carry on rounds.

Results A partial report with data for two patients is shown in Table 1.

Conclusions Automatic reporting of compliance with patient safety protocols is a useful performance improvement tool that further identified areas for improvement. Future study should assess the impact of this tool on actual compliance with patient safety goals.

Automated reporting of safety bundles: streamlining the performance improvement process
W McGee, T Higgins, J Echols, H Nelson, M Tisdwell
Baystate Medical Center, Springfield, MA, USA

Introduction Safety checklists, long used in aviation, have migrated to the critical care setting in an effort to reduce complications and improve patient outcomes. We developed an automated system to provide real-time feedback to the healthcare team on safety bundle compliance in the ICU.

Methods A program was written in Cerner Command Language to automatically search data within the EMR for the most recent values of the following data: ventilation mode, respiratory rate, tidal volume, ideal body weight, administration of any sedative infusion, analgesic infusion, neuromuscular blocking agent, stress ulcer prophylaxis, DVT prophylaxis and regular diet, enteral nutrition, or total parenteral nutrition. Nursing documents oral decontamination, head-of-bed elevation, and whether a sedation vacation was conducted. A customized document was created to capture any patient/family/proxy discussions about end-of-life issues. High and low glucose values and the percentage of all glucose values within the range of 60 to 180 mg/dl are also reported. A summary score was calculated by subtracting (from a baseline of 9) one point each for inappropriate tidal volume, failure to do a weaning trial, lack of oral care, head-of-bed elevation and stress prophylaxis, no sedation vacation and absent DVT prophylaxis, absent nutritional support or glucose values out of range. A perfect score is 9; lower scores indicate an opportunity for improvement. Clinicians access the report from within the hospitals EMR and can view it on a portable device (iPad) or print it to carry on rounds.

Results A partial report with data for two patients is shown in Table 1.

Conclusions Automatic reporting of compliance with patient safety protocols is a useful performance improvement tool that further identified areas for improvement. Future study should assess the impact of this tool on actual compliance with patient safety goals.

Prevalence, clinical management and risks associated with acute faecal incontinence in the critical care setting: the FIRST questionnaire survey
R Binks
Airedale NHS Foundation Trust, Bradford, UK

Introduction The FIRST survey was designed to examine the prevalence, awareness and management of acute faecal incontinence
with diarrhoea (AFI), and the clinical challenges associated with AFI for healthcare professionals (HCP) in the critical care setting.

Methods A descriptive cross-sectional survey. Data were collected from ICUs or critical care units in Germany, Italy, Spain and the UK using a questionnaire. The questionnaire contained 20 questions for completion by HCP and six specific questions for hospital pharmacists or purchasing personnel. Questions concerned the epidemiology, awareness and management of AFI, and associated clinical issues. Analysis of the results was conducted so that respondents remained anonymous.

Results A total of 960 questionnaires were completed (Germany n = 200; Italy n = 261; Spain n = 267; UK n = 232) by nurses (60%), physicians (29%) and pharmacists or purchasing personnel (11%). Estimated prevalence of AFI ranged from 9 to 37% of patients on the day of the survey. The majority of respondents reported a moderately low awareness of the clinical challenges associated with AFI and its prioritisation in their units. Patients with AFI commonly had compromised skin integrity (perineal dermatitis, moisture lesions or sacral pressure ulcers). Reducing the risk of cross-infection and protecting skin integrity were rated as the most important clinical challenges. Forty-nine per cent responded that they had no hospital protocol or guideline for the management of AFI. There was generally low awareness of nursing time spent managing AFI episodes by some hospital personnel, but 60% of respondents estimated that 10 to 20 minutes are required for managing an AFI episode, requiring two or three healthcare staff. The key reported benefits of faecal management systems included: reduced risk of cross-contamination and infection, reduced risk of skin breakdown, and improved patient comfort and dignity. In those not using a faecal management system, the main reason reported was lack of availability or that devices were not included in the hospital guidelines.

Conclusions AFI in the critical care setting may be an underestimated problem that is associated with a high use of nursing time. In many institutions there is a lack of protocols or guidelines, which might improve the management of AFI in the critical care setting.

Patient safety in ICUs: adverse events characterization and potential risk factors

L Zamboni1, R Daud-Gallotti1, K Padilha2, T Vasconcelos3, N Inoue3

Methods A descriptive retrospective study. The study included all adult patients admitted to the ICUs of four tertiary academic hospitals in Brazil, enrolling all adult admissions from June to August 2009. AEs were identified by direct daily monitoring of medical and nursing rounds and chart review. Age, sex, APACHE II scores, length of stay (LOS), and the Nursing Activities Score (NAS) were also registered. The association with the occurrence of AEs was analyzed with logistic regression.

Results A total of 180 ICU admissions were included, regarding 176 patients (male/female: 86/90; age: 52.7 ± 1.8 years). The mean LOS, APACHE II scores and NAS were 10.0 ± 0.8 days, 15.7 ± 0.5 points and 69.0 ± 1.5%, respectively. Nearly 78% of the admissions (141 admissions) suffered 1,065 AEs. The most frequent AEs were: new dermatitis/pressure ulcers (195 events = 18.3% of events); hypoglycemic episodes not related to insulin use (HENDI) (168 events = 15.8%); diagnostic/treatment failures (156 events = 14.6%); and drug AEs (195 events = 18.8%). Those four categories responded for 61.5% of all detected AEs. In the final logistic regression model, three independent variables remained as important risk factors for the occurrence of at least one AE: LOS >3 days, APACHE scores >13 points and NAS >70%, with adjusted OR estimates of 19.5, 3.4 and 3.3, respectively (P < 0.02).

Conclusions This prospective study was essential to identify the proportion of our ICU admissions affected by AEs, disclosing their nature. Our AE rates, affecting nearly 78% of admissions, were higher than those previously described. The direct observation of the AEs contributed to those rates. Six out of 10 AEs corresponded to new cutaneous lesions, HENDI, diagnostic/treatment failures and drug AEs. Length of stay, severity on admission and nursing workload were important risk factors for the occurrence of at least one AE.

Failure to define level 1 care

B Fletcher, C Dames, S Hutchinson, S Fletcher

Methods Data were collected from all inpatients by a team of trained researchers, using hand-held computers, over 5 days. The paediatric, maternal, oncology and emergency units were excluded. A central data controller guarded against omissions or duplications. The acuity criteria dataset was constructed by a regional expert critical care steering committee. The dataset from the university and district hospital sites have not yet been combined.

Results A total of 696 patients were included, representing >97% of patients in surveyed wards. Within the 24-hour period before data collection: four patients had CCOS review, nine had stepped down from level 2/3 care and 51 had MEWS >3. In total, 371 patients (53%) met the criteria of at least one of the definitions, if not all three.

Conclusions A significant proportion of adult patients meet one or more of the current definitions for level 1. We suggest that the current definitions may be unhelpful in identifying at-risk patients outside critical care. Further work is planned to investigate whether certain criteria, or combinations thereof, are better predictors of unmet clinical need, or contribute more to patient safety.

P485 Understanding staff perspectives on collaborative quality improvement in the ICU: a qualitative exploration

KN Dainty1, DC Scales1, B Hales1, T Snuff1, M Zwane1nstein1

1St Michael's Hospital, Toronto, Canada; Sunnybrook Health Sciences Centre, Toronto, Canada

Introduction Despite extensive use of QI collaboratives in healthcare and in critical care, little is known about the impact of the collaborative approach on how the intervention is taken up within participating organizations. This in-depth qualitative study investigates the frontline critical care staff perspective on being involved in a large collaborative network for ICU quality improvement.

Methods One-on-one key informant interviews were conducted with 32 staff members from a sample of the ICUs who participated in the Ontario ICU Best Practice Collaborative between 2006 and 2008. Using a grounded theory approach, open coding was completed by two qualitative researchers. The open codes were then grouped in to broad theme-oriented categories and all text segments belonging to the same category were then compared. The theme-oriented categories became further refined and formulated into fewer analytic categories through an inductive, iterative process of going back and forth between the data and the analytic framework of the study.

Results This research reveals that frontline staff do not feel the need for their unit to be ‘like’ high-performing peer organizations; they feel that belonging to a collaborative provides the chance to be recognized for providing a high level of care despite their inequalities. The existing QI communication structure within ICUs is highly ineffective for staff engagement, and a QI bubble seems to exist in terms of knowledge transfer. Finally, the idea of collaboration is exhibited more internally in increased intra-team cooperation than externally between organizations, where friendly competition is a more prominent driver. A conceptual framework for QI collaborative design is proposed for future testing.

Conclusions These findings indicate that QI collaboratives for ICUs may not function by commonly held inter-organizational assumptions of legitimation, communication and collaboration, which may explain typically mediocre results. Hopefully this work can contribute insight into strategies for more effective use of collaborative efforts for healthcare QI and support new perspectives on their design for use in the ICU environment.

**Improving medication safety on critical care using an anonymous electronic medication incident reporting system**

H Dillon, M Rosbergen, R Wyatt, J Nortje  
Norfolk & Norwich University Hospital, Norwich, UK  

**Introduction** To improve medication safety on the Critical Care Complex (CCC), Norfolk & Norwich University Hospital, an anonymous electronic reporting system was introduced. Reports captured populate a local database of incidents, which identifies themes. Medication incidents are common; studies reveal up to 10.5 incidents per 100 bed-days [1]. Under-reporting of incidents in the CCC was highlighted in a paper-based 2-week reporting project. The electronic reporting system expands this work, introducing a sustainable, integrated reporting system, addressing some of the reporting barriers.

**Methods** A staff survey identified barriers to incident reporting such as access to forms, time taken to complete reports and fear of disciplinary action. An anonymous medication incident system was developed and implemented in the bedside clinical information system, Metavision®. One-to-one education sessions highlighted the system and a survey informed optimal form design. Incidents reported were entered into a database and categorised by time, error types and themes. The database allowed identification of processes needing improvement. Subsequently, targeted changes to the systems surrounding medications were introduced to reduce specific incident types.

**Results** Over 34 weeks, 194 medication incidents were reported. The most common types of incidents were infusion documentation (Gantt), wrong dose, duplication, wrong rate and wrong frequency errors. System changes in response to these errors have reduced their incidence (Figure 1).

**Conclusions** Incident reporting has improved significantly from a baseline of 19 reports in 2 years. The new reporting system has enabled targeted changes, eliminating some of the most common errors, improving medication safety. Fluctuating numbers of reports may still indicate under-reporting. Themes remain that have yet to be addressed.

**Reduction in the incidence of VAP and mortality rates in the ICU after implementation of hand hygiene education protocols and extensive ICU reconstruction work**

K Filos, F Filigou, A Gotsi, D Velissaris, C Sklavou, M Marangos  
University of Patras, School of Medicine, Rion – Patras, Greece  

**Introduction** Education in effective hand hygiene in the ICU is often neglected. The scope of this study is to detect the effects of an educational program on the incidence of VAP in a mixed ICU.

**Methods** Two groups of patients in two comparable time periods (9 months each) before and 6 months after implementation of various hygiene measures were analyzed. The measures implied: implementation of foot-operated hand washbasins, training in the effective use of hand washing followed by use of alcohol-based antiseptic dispensers near each ICU bed, and others. The diagnosis of VAP was by using clinical, microbiological, radiographic criteria, and by the CPIS index. Statistics was with ANOVA and x².

**Results** Despite the comparable APACHE II scores at ICU admission (17.6 ± 6.5 vs. 18.1 ± 6.9) the two groups differed in variables as shown in Table 1. The incidence of VAP and mortality of Group 2 patients were significantly reduced. The RR of death in the control group was significantly increased (RR = 1.364, 95% CI: 1.055 to 1.763). The mortality of trauma patients in the protocol group was significantly lower (Group 1: 57.1% vs. 0% (Group 2), P < 0.05).

**Conclusions** The implementation of protocols regarding hand hygiene by healthcare professionals in the ICU, together with a reconstruction, may lead to a significant reduction in the incidence of VAP and mortality both in the crude ICU patient population and in the subgroup of polytrauma patients.

**Paediatric admissions to an adult ICU in a district general hospital in the UK**

A Hazara, V Singh, P Davoudian  
Addenbrooke’s NHS Foundation Trust, Cambridge, UK  

**Introduction** Data were collected for paediatric admissions to an adult ICU in a district general hospital in the UK over a 6-year period to look for feasibility and the associated problems of training and skills after centralisation of PICUs in the country.

**Methods** We searched the ICNARC database for all entries relating to children for their age, gender, and diagnosis at admission, source of referral, length of stay, level of support, outcome/discharge and any other problems highlighted during their stay in the unit between the years 2002 and 2009.

**Results** Thirty-eight children were admitted to the adult critical care unit during this period. The age range was from 6 months to 16 years (average 9.12 years). Seventeen patients were male and 23 female. The most common reason for admission to the unit was respiratory problems followed by trauma. Seventeen patients received level 2 care and 21 received level 3 care. Twenty children needed endotracheal intubations, 12 needed arterial lines, 10 needed central lines and two needed intercostal drains. Twenty-one patients received sedation, most commonly with midazolam and morphine. The average length of stay in the ITU was 15 days and 80% of patients were discharged from the ITU within 2 days. Twenty-two patients were discharged to the ward.

Data are in total numbers (n) or proportions (%). *P < 0.05, **P < 0.01 for comparisons between two groups. *Relative risk = 1.364 (95% CI: 1.055 to 1.763) compared with Group 2 (protocol).
and 16 were transferred to a specialist ICU. Thirteen of these specialist transfers were to a local specialist centre and three to other specialist centres. The national paediatric transport service was used in seven instances, and local service in nine instances. The number of admissions to the ICU was few, and it was able to manage the cases and institute appropriate therapy. Less than 50% of these patients were transferred to a specialty hospital and most local level 2 care could be managed in the district general hospital. In those needing transfer to specialist units, the availability of protocols for sedation and analgesia resulted in less delay in handover and transfers. Communications between various teams involved in transfer and preparation was effective and no critical incidents were reported.

Conclusions With the specialist centre bed occupancy remaining high, district general ICUs provide more and more ongoing level 2 care to critically ill children. This also confirmed the findings of other studies that widespread use of a specialist retrieval service has not resulted in loss of vital stabilisation skills.

Factors associated with compassion fatigue among ICU nurses in Greece

Introduction ICU nurses work in a demanding environment and they are repetitively exposed to traumatic situations and stressful events. There is a growing interest in the phenomenon of compassion fatigue (CF) and its impact on healthcare professionals; however, its impact on ICU nurses is basically unknown. The primary aim of this study was to investigate the risk for CF (the trauma suffered by the helping professional) and burnout (BO – emotional exhaustion, depersonalization and reduced sense of personal accomplishment), and the potential for compassion satisfaction (CS – the fulfillment from helping others and positive collegial relationships) among ICU nurses. An additional goal was to test the relationship between nurses’ characteristics (demographic and occupational) and CF risk.

Methods The Professional Quality of Life Scale (ProQRL IV, CF, BO and CS subscales) and a demographic tool were distributed to 335 ICU nurses in 22 public hospitals in the Athens greater area, Greece.

Results Findings revealed that 57.9% of ICU nurses are at the high level of risk for CF and 56.1% are at the high level of risk for BO, while 61.5% of participants reported low potential for CS. Female nurses (P = 0.016), with low income (P = 0.041), married (P = 0.001) or widowed (P = 0.023), who work as assistant nurses (P = 0.014) and also registered nurses with Master of Science (P = 0.008) or Nursing Specialty (P = 0.003) were found to have higher risk for CF. Additionally, higher risk for CF had also participants who characterized their relationship with their colleagues as neutral (P = 0.001) or bad (P = 0.030), believed that the staff worked sometimes as a team (P = 0.016), spend 26 to 100% of their work time in direct contact with the patients (26 to 50%: P = 0.001, 51 to 75%: P = 0.043, 76 to 100%: P = 0.024) and described their mental health as poor (P = 0.001), average (P <0.001) or good (P <0.001). Nurses who want to retain in the ICU (P = 0.003) and those who want to leave the hospital in few years (P = 0.005) were associated with lower risk for CF.

Conclusions The high prevalence of CF in our sample indicated that large numbers of ICU nurses may be experiencing these negative effects. Knowledge of CF-related variables may help healthcare organizations identify nurses at risk, provide intervention strategies to maintain healthy outcomes for nurses and increase job satisfaction.

Burnout in ICUs in Portugal: is there? Are there differences between doctors and nurses?

C Teixeira1, S Pereira2, O Ribiero3, A Fonseca4, A Carvalho4
1Centro Hospitalar do Porto, Portugal; 2Universidade dos Açores, Angra do Heroísmo, Portugal; 3Faculdade de Medicina do Porto, Portugal; 4Universidade Católica Portuguesa, Porto, Portugal

Introduction The aims were to identify whether there is burnout and the burnout levels of doctors and nurses working in ICUs (adult polyvalent units in northern Portugal). Also, to identify factors that may lead to the development of burnout in doctors and nurses working in the ICU.

Methods Application of a self-completion questionnaire with three items: the sociodemographic data of the study population, experiences in the workplace, and the Maslach Burnout Inventory – General Survey (Portuguese Version for Investigation 2006). For the implementation of methodological tools, we requested the authorization of the relevant institutional bodies, the ethics committee and directors of services. The professionals who participated in the study were asked for informed consent, whether formal or informal. Observation of the contexts of work and interviews was also done. In this study we will focus on the results of the questionnaire. Statistical analysis was performed using SPSS v.17.0.

Results A total of six hospitals, 10 polyvalent adult ICUs in the north of the country, 300 professionals, 73% nurses. Age of respondents was a median 32 years, with 8 years of professional experience and 4 years on the ICU. Results of the MBI: average levels of burnout in physicians and nurses working in the ICU. The risk of developing burnout is highest being a nurse 1:54 OR, yet there is no statistically significant difference at 95% (0.837, 2.834). Nine percent of professionals studied showed burnout, 31% with Burnout syndrome and high risk of burnout. Distribution of levels of burnout by occupational category: higher levels of emotional exhaustion in nurses, personal and professional achievement smaller in nurses, and higher depersonalization in doctors.

Conclusions The results of the study underline the importance of promoting the prevention of burnout in doctors and nurses in the ICU.

Medical handovers in the ICU: a snapshot of practice in the South West of France

G Brenier, T Geeraerts, O Fourcade
CHU Toulouse Prupon, Toulouse, France

Introduction Medical handover is critical for quality of care in the ICU. Time assigned to medical handovers can vary across different units, with significant impact on the organization of medical work. We aimed to study the time spend for medical handover in ICU and its variation across academic, general and private hospitals in the area of the South West of France, the Midi-Pyrénées region.

Methods Between August and October 2010, we questioned by telephone 86 physicians issued from 19 different ICUs. This prospective observational study mainly focused on four items: unit characteristics, health diary organization, medical handover procedures, and self-assessment of satisfaction for medical handover (numeric scale from 0 to 10).

Results Eleven general hospital centers, three private hospitals, and five university hospitals were concerned by the survey. The mean time spent for medical handover was 59 ± 35 minutes on Monday morning, significantly longer than other days, evening, and weekend handovers (P <0.001 for all comparisons). When reporting it with the number of ICU beds, the time spent for handover per patient was significantly shorter in private hospitals compared with general and academic hospitals (P <0.03 for all comparisons). This was true for every day. The median satisfaction for quality and duration were both 8, with a significantly
higher satisfaction in general hospital ($P = 0.001$ for comparison vs. other hospital for both). See Figure 1.

**Conclusions** Time spent for the medical ICU is important, with an approximate total time of 1 hour 30 minutes on Monday, and 1 hour the other days. Physicians in private hospitals spend less time for medical handovers. This fact should be considered for medical timework organization, especially in academic hospitals and in hospitals with large ICUs.

**P492**  
**Ratio of observed to predicted deaths in pediatric patients after introducing a closing policy in a general ICU**  
Y Ueno1, H Imanaka2, J Oto2, M Nishimura2  
1The University of Tokushima Graduate School, Tokushima, Japan;  
2Tokushima University Hospital, Tokushima, Japan  

**Introduction** The purpose of this study was to investigate whether the introduction of a closed ICU policy affected the prognosis of the critically ill pediatric patients in a general ICU.

**Methods** Our ICU is a general acute-care one. The Department of Emergency and Critical Care Medicine was established in January 2004. Since then, full-time intensivists performed daily rounds and decided the ventilatory setting, cardiovascular treatment and antimicrobial agents (closed policy). We collected the Pediatric Index of Mortality 2 (PIM2) score for each pediatric patient (≤15 years old) admitted to our ICU from 2001 to 2009. We divided the patients into three terms: the early (2001 to 2003), middle (2004 to 2006), and latest (2007 to 2009) groups. We obtained the predicted number of deaths by summing the PIM2 score for every patient. We compared the ratio of observed to predicted deaths (O/P ratio) between the three groups.

**Results** The patient profile and results are shown in Tables 1 and 2. In total, 532 pediatric patients were collected. The PIM2 score increased significantly from 0.066 ± 0.130 in 2001 to 2003 to 0.114 ± 0.239 in 2004 to 2006 and to 0.086 ± 0.147 in 2007 to 2009. However, the O/P ratio decreased from 1.49 in 2001 to 2003 to 0.82 in 2004 to 2006 and 0.82 in 2007 to 2009.

**Conclusions** The O/P ratio improved after the establishment of a closed policy in our general ICU.

**P493**  
**Safety programme reduces ICU mortality**  
KD Rooney, R Sundaram, L Gibson, RJ Price  
Royal Alexandra Hospital, Glasgow, UK  

**Introduction** One in 10 patients admitted to Scottish hospitals are unintentionally harmed and around 50% of these events could have been avoided if lessons from previous incidents had been learned. A National Audit Office report estimated that patient safety incidents cost the NHS an estimated £2 billion a year.
Methods We identified a minimum of eight main elements that we should concentrate on in order to produce reliable critical care. They included VAP, CVC insertion and maintenance, peripheral vascular catheter maintenance, daily goals, multidisciplinary ward rounds, hand hygiene, and glycaemic control.

Results We have seen significant reductions in our VAP and Cr-BSI rates with more than 230 days and 440 days between events achieved, respectively. Despite an increase in the complexity and severity of cases in the last year due to Pandemic H1N1 2009, our average length of stay (Figure 1) has still reduced by 2.4 days with a 0.23 reduction in our standardised mortality ratio (Figure 2) from 0.92 to 0.69.

Conclusions The public display of our infection rates has helped change the culture in our ICU to one of transparency and safety. Multiple small-scale tests of change are integral to changing practice in a high-risk environment. Bundles of care, daily goals and checklists all help produce high-quality reliable healthcare.

Critical care outcome of pulmonary artery hypertension
A Philips, J Hurdman, B Batuwitage, D Kiely, G Mills
Sheffield Teaching Hospitals, Sheffield, UK

Introduction Critical care (CC) outcome in pulmonary hypertension (PH) is not well documented, but is generally assumed to be poor. We therefore investigated the critical care outcome in 8 years of noncardiothoracic admissions to a PH supraregional centre.

Methods We recorded the following data in PH patients admitted to CC: demography, aetiology, cardiovascular parameters including NYHA classification, R heart catheter and shuttle test distance (most recent assessment) along with organ support data. We recorded the length of stay (hours) in CC, CC and hospital outcome, 1-year survival and eventual outcome.

Results Forty-seven patients were admitted (33 women), six required invasive ventilation, another six required non-invasive ventilation (NIV), 18 needed inotropic support and nine required CVVH. For survival to discharge, ROC analysis of shuttle distance demonstrated an asymptotic significance of 0.04 and an area of 0.71 (95% CI = 0.52 to 0.91) with 83% sensitivity and 65% specificity for a shuttle of 255 metres. Those with a shuttle over 255 metres had an average unit survival of 94%, 88% at hospital discharge and 47% at 1 year. Those below 255 metres had an average survival of 56%, 44% and 33%, respectively. Five out of six invasively ventilated patients died in hospital, but one lived for more than a year after discharge. Three out of six patients receiving NIV died in hospital but three lived for more than a year after discharge. Seventeen out of 18 who required inotropic support were dead at 1 year and 74% died before hospital discharge. For CVVH, five died and four lived. Overall survival: 64% survived to leave CC, 55% were discharged home alive and 34% were alive at 1 year. See Table 1.

Conclusions More than one-half of PH patients admitted to CC survive to be discharged home. Shuttle distance gives an indication of likely average survival.

Figure 2 (abstract P493). Standardised mortality ratio.
Unfortunately HSCT is frequently associated with complications such as sepsis, respiratory failure and graft versus host disease (GVHD) requiring ICU admission. Traditionally the prognosis of these patients has been poor with an in-hospital mortality of 60 to 95% [1]. The aim of this study was to determine outcomes and establish prognostic indicators of in-hospital mortality. This may assist clinicians in identifying patients most likely to benefit from ICU therapy.

**Methods** Following research approval, a retrospective study was undertaken in a 12-bed specialist cancer ICU over a 5-year period (October 2004 to September 2009). Patient variables including demographics, haematological diagnosis, reason for ICU admission, type of transplant, APACHE II, number of organ failures and type of organ support were recorded. The primary objective was to determine ICU, hospital and 6-month mortality. The secondary objective was to identify key prognostic variables in determining in-hospital mortality using univariate and multivariate analysis.

**Results** Eighty-four patients with HSCT were admitted to the ICU following HSCT. Patient characteristics: median age 53 (range 19 to 76), female (43%), haematological diagnosis (49% leukemia, 30% myeloma, 20% lymphoma), previous transplant (26%) and allogenic transplant (61%). Common reasons for ICU admission were respiratory failure (49%), sepsis (19%) and acute renal failure (11%). Median APACHE II was 20 (range 9 to 36) and number of organ failures was 2.5 (range 0 to 5). In the first 24 hours of ICU admission, 65% of patients received mechanical ventilation, 49% renal replacement and 57% vasoressor therapy. ICU, in-hospital and 6-month mortality rates were 38%, 51% and 63%, respectively. Univariate analysis revealed allogenic transplant, GVHD, mechanical ventilation, vasoressor support, time post transplant >30 days and organ failure >2 were all significant predictors of in-hospital mortality with P values of <0.001, 0.02, 0.001, 0.02, 0.01 and 0.002 respectively. Multivariate analysis revealed that allogenic transplant, mechanical ventilation and time post transplant >30 days were independent prognostic predictors of in-hospital mortality.

**Conclusions** Our outcome data were favourable in comparison with other published studies. Allogenic transplant, mechanical ventilation and time post transplant >30 days were independent factors that predicted poor outcome.

**Outcome of haematology patients admitted to intensive care in a tertiary centre: primary haematological diagnosis, recent chemotherapy and bone marrow transplant are not associated with outcome**

R Jose, I McDonald, P Peefer, S Shaw, B Agarwal
Royal Free Hospital, London, UK

**Introduction** Acute illness in patients with underlying haematological disease is associated with poor prognosis. Recent reports suggest improved outcomes in these patients except for those with bone marrow transplantation (BMT) or recent chemotherapy [1]. We sought to audit the overall outcome and potential determinants of outcome in these patients admitted to our ICU.

**Methods** Retrospective data on demographics, underlying haematological diagnosis, BMT, recent chemotherapy, reason for acute illness, severity of acute physiological derangement (severe acute physiological score (SAPS), number of failed organs, need for invasive mechanical ventilation and renal support), and ICU and hospital outcomes were collected for 106 consecutive admissions (97 patients) between January 2005 and December 2008. Re-admissions were excluded (9/106 patients). Data were analysed by SPSS software.

**Results** Of the 97 patients, NHL (30.9%) and AML (26.8%) accounted for most haematological diagnoses. A total 24.7% were post-BMT, and 36.1% had chemotherapy within a month of admission or on the ICU. The mean (SD) age was 49 (15), SAPS 55 (16) and 56.7% were males. The mortality at ICU and hospital discharge was 51.5% and 63.9%, respectively. Gender, neutropaenia (<1 x 10^9/l), haematological diagnosis, admission reason, HIV status, BMT and recent chemotherapy were not predictive of ICU or hospital outcome (P>0.05). SAPS, invasive mechanical ventilation (IMV), renal support (RS) and sequential number of organs supported (OS) were predictive of both ICU and hospital mortality outcomes (P<0.05).

**Conclusions** There is ongoing heightened risk of mortality in patients with haematology diagnoses admitted to the ICU with acute illness, related to both the severity of the initial physiological disturbance and requirements for organ support. In our patient population, BMT and recent chemotherapy were not associated with increased mortality, but this will need further evaluation with a larger sample size.

Feasibility and utility of frailty assessment in the over 80s on critical care
B Charles, R Porter, D Bryden
Sheffield Teaching Hospitals NHS Trust, Sheffield, UK

Introduction A recent UK-wide audit in perioperative care of the over 80s recommended the use of frailty assessment as an independent marker of risk in older people [1]. Our critical care unit (CCU) has a fully integrated patient data management system (Metavision®) incorporating notes, patient data and laboratory results. We wished to determine the feasibility and utility of performing frailty assessments using our existing data collection tools on all patients over 80 years old. Methods Retrospective data collection identified all patients >80 years old admitted to CCU over a 22-month period to November 2010. Frailty was assessed by means of the Canadian Study of Health and Aging index, which has been validated as a simple assessment tool [2]. APACHE II scores and numerical assessments of polypharmacy were also noted.

Results A total of 112 patients were identified with a median age of 83 years (80 to 92). Seventy-three per cent (n = 83) were discharged from critical care alive and 57% survived to leave hospital. Survival for those aged under 80 was significantly higher with 83% (P = 0.01) and 73% (P = 0.00) surviving until critical care and hospital discharge, respectively. Frailty was only able to be assessed in 66 (58.9%) patients. Scores were as shown in Figure 1 but bore no relationship to survival. On multivariate analysis, APACHE II scores but not polypharmacy or frailty score were independent predictors of mortality.

Conclusions Our patients had a significantly lower unit and hospital survival than those aged under 80 and this may reflect the need for better assessment tools of frailty and co-morbidity in the critical care population. Current critical care data collection is not sufficient to adequately assess and record frailty in our unit. The National Institute for Health and Clinical Excellence will be producing a guideline for critical care in older patients and this should include a review of frailty assessment.

Is age a predictor of mortality in medical high-dependency units?
E Hood, A Bhanu, D Pandit, A Michael
Russells Hall Hospital, Dudley, UK

Introduction The population aged >65 years is set to rise by 32% by 2033. As resources are limited, difficult decisions regarding access to high-dependency care for the older person will become increasingly important. The aim of this study was to determine whether age is a predictor of mortality in patients admitted to an open medical high-dependency unit (MHDU).

Methods A prospective observational cohort study of 100 consecutive patients admitted to a MHDU with a medical diagnosis over a 3-month period. The primary endpoint was 30-day mortality.

Results Overall mortality at 30 days was 21% (n = 21). Forty-one per cent of patients were aged <65 years, 29% 65 to 74 years and 30% 75+ years. There were no significant differences in mortality between age groups (12%, 31% and 23%, respectively). When considering APACHE II scores ≥25, there was no significant difference in mortality between groups (12%, 31% and 23%, respectively). When considering APACHE II scores ≥25, there was no significant difference in mortality between age groups (35% <70 years (7/20) vs. 29% ≥70 years (4/14), P = 1.000). The final model at multivariable regression analysis identified that ≥2 organ support (odds ratio = 10.843, 95% CI = 3.281 to 35.836) and preadmission moderate/nursing home care (4.437, 95% CI = 1.053 to 18.697) were significantly associated with worse outcome. ROC curve analysis for death showed that APACHE II score was a moderate discriminator (area under the curve = 0.64, 95% CI = 0.53 to 0.75), and age (0.60, (0.48 to 0.72)) was a poor predictor for 30-day mortality. The majority of survivors (88%) were discharged at their preadmission functional status; those who declined in function were not significantly older than those who did not. See Figure 1.

Conclusions Age does not predict outcome from MHDU. Patients requiring ≥2 organ support and/or higher levels of preadmission home support had higher mortality. Selected elderly medical patients can be expected to have outcomes comparable with younger patients and should not be denied MHDU care.

P502
Inadvisably presenting APACHE scores as parametric data: a study of 200 original articles from leading journals
R Kam1, C Bunce1, JM Handy1
1Imperial College London, UK; 2Moorfields Eye Hospital NHS Foundation Trust, London, UK; 3Chelsea & Westminster Hospital, Imperial College London, UK

Introduction The APACHE score, used to indicate severity of systemic illness in patients, is the sum of separate points given for different aspects of organ dysfunction. It is therefore ordinal data, and in intensive care patients should not simply be assumed to be well approximated by a normal distribution. This study aimed to discover what proportion of recent intensive care literature is presenting this score inadvisably as normal data.

Methods Twenty of the most recent original articles containing ‘APACHE’ or ‘Acute Physiology and Chronic Health Evaluation’ were identified from each search engine of 10 highly cited journals with notable intensive care literature content. Studies presenting an average score and a measure of central spread were included. Statistical methods used were recorded.

Results Approximately 70% of identified papers presented APACHE data as means and standard deviations, and 48% used these data in parametric tests. Eighty-one per cent did not mention assessment of skewness or kurtosis and only 7% documented the test used to assess whether the distribution appeared normal.

Conclusions Inadvisable presentation and processing of APACHE data is commonplace in critical care journals and authors should exercise greater awareness of the potentially skewed distribution of the data. Medians and interquartile ranges suit its ordinal nature better. Subjecting APACHE data to parametric analysis when non-normally distributed will increase the risk of type 1 or type 2 errors depending on the nature of departure from non-normality.

and use of vasopressors were significant baseline characteristics (Table 1). All of the scores tested had good efficacy but none reached statistical significance (Table 2).

Conclusions The SAPS II and APACHE III scores showed good accuracy, calibration and mortality prediction. Nevertheless, the difference in efficacy was not statistically significant and the choice of scoring system may depend on the ease of use and local preferences.

PS04
Do scoring systems predict mortality following emergency abdominal aortic aneurysm repair? The Norwich experience
S Kumar, J Nortje
Norfolk & Norwich University Hospital, Norwich, UK

Introduction APACHE II scores [1] and Glasgow Aneurysm Scores (GAS) [2] are commonly used in ICUs to predict mortality. These scoring systems (scores α mortality), when applied to postoperative emergency open abdominal aortic aneurysm (AAA) repair patients, yield varying results. We applied these scoring systems to our patients to establish their predictive value in our clinical setting.

Methods This retrospective audit included patients who underwent emergency open AAA repair and were admitted to our ICU, over a period of 1 year (November 2008 to November 2009). These patients were identified from our local ICU database (Metavision®) and scores (APACHE II and GAS) were calculated for each of these patients. The mortality rates were compared with the national average [3].

Results A total of 98 AAA repair patients were identified, of whom 35 patients (32 males and three females) had undergone emergency (ruptured) repair. Seven patients (20%), including two females, died in the ICU. There is an increase in mortality with increasing APACHE II scores (Figure 1). The same does not apply for GAS scores but all the patients who died had a GAS score >89. Our mortality rate was 20% compared with the national mortality of 38% (Figure 2).

Conclusions APACHE II scores seem to be more predictive of our unit AAA mortality rates than GAS scores. We aim to apply these scores to a larger dataset and also determine possible reasons for improved survival.

PS05
Influence of resuscitation status on the performance of APACHE III, APACHE IV and SAPS III
MT Keegan, O Gajic, B Afessa
Mayo Clinic, Rochester, MN, USA

Introduction The presence of a do-not-resuscitate (DNR) order is an independent predictor of mortality in ICU patients [1]. Of the major ICU prognostic scoring systems, only MPM III includes DNR status as a predictor. The influence of DNR status on APACHE III and IV and SAPS III is unknown. We hypothesized that there would be differences in the performances of APACHE III, APACHE IV, and SAPS III when DNR status was included as a predictor variable.

Methods A retrospective cohort study was performed. Demographic, physiologic and outcome data for 2,596 patients admitted to one of three ICUs (medical, surgical, mixed) at our tertiary referral center in 2006 were collected. The presence or absence of a DNR order on ICU admission and at the end of the first ICU day was recorded. The performance of each of the four models, with and without inclusion of first-day DNR status, was assessed using the area under the receiver operating characteristic curve (AUC) for discrimination and the Hosmer–Lemeshow statistic (HLS) for calibration. Comparison of model performance was as described by Hanley [2].

Results Of the 2,596 patients studied, 211 (8.1%) and 252 (9.7%) had DNR orders on ICU admission and at the end of the first ICU day, respectively. Two hundred and eighty-three patients (10.9%) did not survive to hospital discharge. A total 19.4% of the nonsurvivors had DNR orders on admission versus 6.7% of the survivors, P < 0.01. At the end of the first ICU day, 32.5% of nonsurvivors were DNR versus 6.9% of survivors, P < 0.01. The AUCs (95% CI) of the models for prediction of hospital mortality were 0.868 (0.854 to 0.880), 0.861 (0.847 to 0.874) and 0.801 (0.785 to 0.816) for APACHE III and IV, and SAPS III, respectively. When DNR status at end of the first ICU day was included in the models, the AUCs were 0.876 (0.855 to 0.897), 0.868 (0.846 to 0.891), and 0.816 (0.791 to 0.841), respectively. There were no significant differences between the discriminative ability of the models with and without DNR status (APACHE III P = 0.103, APACHE IV P = 0.145, SAPS III P = 0.072). The HLS for the models with and without DNR status were 33.7 and 29.3, 31.0 and 33.3, and 36.6 and 29.0 for APACHE III and IV and SAPS III, respectively. Each of the HLS generated P < 0.05.

Conclusions Neither the discrimination nor calibration of APACHE III and IV and SAPS III were significantly improved by the inclusion of resuscitation status at the end of the first ICU day in the prognostic models.

Limitations of the use of the Glasgow Coma Scale in intensive care patients with non-neurological primary disease: a search for alternatives
PV Dong, OL Cremer
University Medical Centre Utrecht, the Netherlands

Introduction Numerous scoring systems have been devised to assess the severity of illness and predict outcome in critically ill patients in the ICU, many of which incorporate the Glasgow Coma Scale (GCS) as a key component. However, the GCS requires observation of a verbal score (which is often unavailable in the ICU), must be interpreted in cases of concurrent sedation, and is insensitive to more subtle derangements of consciousness (such as delirium). Furthermore, its relationship with outcome may be nonlinear. In this study we quantified the practical limitations of using the GCS in daily routine. We then aimed to provide alternative methods for neurological assessment scoring in case of missing GCS scores.

Methods We performed an observational study of all patients admitted to a large tertiary ICU from January 2009 until September 2010. Patients following elective surgery, having an uncomplicated stay <96 hours, were excluded from analysis. We collected data on neurological status and sedation. All variables were assessed for their ability to predict hospital mortality, using multivariate logistic regression analyses that included the variables of primary interest as well as any relevant covariates.

Results In total, 1,128 patients were included (62% males, mean age 58 ± 17 years, 40% surgical admissions). We observed an overall 26% hospital mortality rate (compared with 30% predicted by the APACHE IV model). In patients with maximum GCS motor scores of M1 and M2–3 on their first day in the ICU, the mortality rate was 62% and 79%, respectively. Within the large majority of patients with a M6 score, we observed a broad range of clinical variance, expressing low discriminative ability of the GCS motor score. We found inferior predictive power of the APACHE IV model in patients with non-neurological primary disease (c statistic = 0.75 to 0.79) compared with patients with acute neurological injury (0.85 to 0.86). The predictive power of the APACHE IV model improved when substituting missing GCS components by other neurological observables.

Conclusions The GCS is difficult to obtain and interpret, and shows inconsistent predictive power. In patients with non-neurological primary disease, the use of alternative observables, such as pupillary anomaly, RASS score and sedative use, may serve as a substitute score in cases of missing or unobservable GCS assessments.

Does an open level 2 medical high-dependency unit improve outcomes for critically ill patients? Using the APACHE II scoring system in a district general hospital in the UK
V Hurley, D Pandit
Russells Hall Hospital, Birmingham, UK

Introduction Improving care of acutely ill medical patients led to formation of a six-bed level 2 medical high-dependency unit (MHDU). The aim of this study was to look at outcomes of medical patients admitted to an open level 2 MHDU.

Methods One hundred and nine patients were consecutively admitted to the MHDU in a prospective observational study. APACHE II derived mortality scores averaged for two groups of patients – those who survived the admission and those who did not – and were assessed using a chi-squared test.

Results A total 48.6% of patients were male, mean age 59.3 years (range 0 to 98 years). Average total length of stay in hospital was 16.55 days with average 4.29 days in the MHDU (range 0 to 18 days). In total, 34.9% admissions were respiratory in origin, 22% sepsis, 10% GI, 7.4% poisonings, 5.5% other, 4.6% renal, 3.6% cardiac, 2.8% neurological and <1% unclassified. A total 29.3% of patients were admitted directly from A&E, 37.6% from the emergency admissions unit and 33% from the wards (27% of these from ITU). Two per cent of patients required ITU admission after the MHDU. Twenty-two patients out of 109 died during this admission, 13 of them while admitted to the MHDU. Deaths were classified according to diagnosis on admission to the MHDU, with 45% with GI disease dying, 29% with sepsis, 22% endocrine and 21% respiratory. These patients were deemed not suitable for escalation to level 3 care. Of 109 patients, full APACHE II data were available for 87. Of this subcohort, 16 patients died and 71 survived. Expected values were calculated and predicted that 26 should have died and 61 survived (P <0.05) from the APACHE II data.

Conclusions The cost of NHS care is becoming increasingly important in the UK and anecdotal evidence suggests a high proportion of patients managed in level 3 care could more appropriately be managed with a lower level of care ideally in an HDU setting, while decisions can be made whether the physiological state of the patient justifies escalation of care. This observational study raises questions about appropriateness of admission to MHDU and has led to improvement of gatekeeping to the unit. This study also demonstrates increasing involvement of critical care in managing end-of-life challenges. We have used this study to demonstrate to our colleagues what critical care can and cannot offer. Future studies to characterise performance of our unit will use the SAPs and risk profile management method.

ManChEWS: Royal Manchester Children’s Hospital early warning score
V Joshi, R Barber, R Yates
Royal Manchester Children’s Hospital, Manchester, UK

Introduction Unrecognised clinical deterioration resulting in near or actual cardiorespiratory arrest in hospitalised children sadly still occurs. The majority of these events may be preventable. Royal Manchester Children’s Hospital (RMCH) introduced a simple track and trigger Early Warning System (ManChEWS) in 2005 by which variation in six key physiological parameters is scored according to a traffic-light system in routine nursing observations. The aim was to evaluate use of ManChEWS since its introduction, in order to allow continued improvement and development.

Methods Three audits were carried out: an audit to evaluate ManChEWS in emergency admissions to the PICU or PHDU (2006 to 2007), a prospective audit of children who trigger EWS on the ward but do not require admission to the PHDU/PICU (2009), and an audit to evaluate the use of ManChEWS in children that died between 2005 and 2008 following an acute deterioration on the wards.

Results ManChEWS correctly identifies the clinically deteriorating child on the ward. ManChEWS is over-triggering, leading to staff becoming immune to triggers. This is due to the high frequency of underlying illness in children admitted to RMCH. Medical staff are not currently redefining parameters for children with abnormal baseline parameters. ManChEWS is not being universally used in RMCH. Twenty-five per cent of deaths in RMCH were attributable in part to the failure to recognise a sick child. These might have been prevented by the correct use of ManChEWS.

Conclusions ManChEWS correctly identifies the deteriorating child and offers staff a clear pathway for escalation of care and senior review. ManChEWS is not being used correctly on the wards by medical or nursing staff. For patients with underlying disease, ManChEWS over-triggers, leading to staff becoming immune to triggers. Developments and the future Development of an EWS Steering Group. Daily review of patients triggering ManChEWS by development of an outreach team. Electronic EWS implementation across the Trust. Patients with underlying illness may have individualised parameters set by senior medical staff.

Gastrointestinal failure score alone and in combination with SOFA score in the assessment of the critically ill patients
N Abed 1, L Mahammedi 1, A Metwally 1, M Hussein 1
1Cairo University, Cairo, Egypt; 2Theodor Bilhars Research Institute, Cairo, Egypt

Introduction Gastrointestinal problems occur frequently and are associated with an adverse outcome in critically ill patients; despite this, gastrointestinal (GI) function is not included in any of the widely used scoring systems assessing organ failures in critical illness. Several studies have demonstrated an impact of intra-abdominal hypertension (IAH) on mortality [1]. With the goal of developing a scoring system for GI failure, Reintam and colleagues combined GI symptoms and IAH into a five-grade scale – the Gastrointestinal Failure Score – and tested it among critically ill patients in Estonian ICUs [2]. The aim of our study was to evaluate the GIF score in our Egyptian ICUs regarding validity and impact on mortality and comparing this with the SOFA score.

Methods We studied 109 mechanically ventilated patients on day 1 admitted to the general ICU of Kasr El Aini Hospital and Theodor Bilharz Research Institute in the period from March 2009 to November 2009. The SOFA + GIF scores were calculated each day by summarizing the SOFA score and the GIF score of the respective day in each patient.

Results FI developed in 35.8%, IAH in 26.9% and both of them together in 14.7% of all patients. Compared with patients with mean GIF = 0, patients with mean GIF higher than 0 and lower than or equal 2 and mean GIF higher than 2 show higher ICU mortality (100%, 81.4% vs. 48.2% P <0.0001), respectively. The GIF score integrated into the SOFA score allowed a better prediction of ICU mortality than the SOFA score alone shown by AUC 0.92 and 0.890, respectively. The GIF score alone shown by AUC 0.92 and 0.890, respectively.

Conclusions The mean GIF score in the first 3 days on the ICU demonstrated a high prognostic value in prediction of ICU mortality. Further multicenter studies should confirm whether GIF score could be advocated as an adjuvant subscore for GI tract assessment in the SOFA score.

How high must lactate be to predict an adverse outcome?
A Reintam Blaser, J Starkopf
University of Tartu, Estonia

Introduction We aimed to clarify the associations between lactate levels and ICU mortality and their changes over 6 years in one ICU.

Methods All patients admitted to the general ICU of university hospital from 2005 to 2010 were studied. Highest lactate on admission day in the ICU was documented.

Results In total, 1,830 patients were treated, 417 were excluded due to incomplete data and 1,413 patients were included in the study. Survivors had a mean blood lactate level of 2.8 ± 3.3 versus 8.9 ± 7.2 mmol/l in nonsurvivors (P <0.001). The lactate levels of survivors versus nonsurvivors over the years are presented in Figure 1. The survival in different lactate groups is presented in Figure 2.

Conclusions There is a linear correlation between blood lactate levels and ICU mortality. A considerable amount of patients with very high lactate levels survive the ICU. There is no certain lactate level that may reliably predict an adverse outcome.

Outcome prediction in haematological patients requiring admission to the ICU
S Gopal 1, N Green 1, M Myint 2, A Jacobs 2
1Heart and Lung Centre, Wolverhampton, UK; 2New Cross Hospital, Wolverhampton, UK

Introduction The outcome of haematological patients admitted to the ICU is improving [1,2]. However little is known of the predictive factors that determine hospital outcome in this group of patients. We hypothesised that certain haematological factors may predict a worse outcome in these patients requiring admission to the ICU.

Methods We retrospectively reviewed all haematological patients admitted to a 15-bed medicsurgical ICU of a teaching hospital over a 5-year period from 1 April 2005 to 31 March 2010. Data on validated outcome predictors including age, APACHE II score, APACHE II predicted mortality, length of ICU stay, and requirement for mechanical ventilation were collected. Furthermore outcome predictors deemed important in haematological patients were also collected, including neutropaenic status at onset of illness, malignancy status at onset of illness and whether chemotherapy was received within 30 days of admission to the ICU. We performed logistic regression analysis to model these variables against hospital mortality.

Results Fifty-six haematological patients were admitted to the ICU during the study period. Data from three patients were incomplete and they were therefore excluded from the analysis. Mean age (SD) 54 (18.5) years; mean APACHE II score (SD) 23.4 (6.8); mean APACHE II predicted mortality (SD) 50.6 (23.8); mean ICU stay (SD) 4.6 (3.7) days. Twenty patients (35.7%) were mechanically ventilated on admission to the ICU. Thirteen patients (26%) were neutropaenic at onset of critical illness; 40 patients (75.5%) had a haematological malignancy and 31 patients (56.6%) had received chemotherapy within 30 days of the onset of critical illness. The standardised mortality ratio (95% CI) for this cohort of patients was 0.86 (0.82 to 0.91). Logistic regression analysis revealed no relationship between these variables and hospital mortality even after adjusting for age, APACHE II score, length of ICU stay and requirement for mechanical ventilation. Adjusted OR (95% CI) for neutropaenic status at...
onset of critical illness was 1.8 (0.3 to 9.1) \( P = 0.46 \). Malignancy at onset of illness OR was 0.54 (0.1 to 3.7) \( P = 0.53 \). Chemotherapy within 30 days of admission to ICU OR was 0.4 (0.1 to 2.2) \( P = 0.30 \).

**Conclusions** Haematological factors including neutropenia, haematological malignancy and recent chemotherapy do not predict worse outcomes in this group of patients. With improving mortality rates, all haematological patients should be considered for admission to the ICU.

HIV-infected patients in the ICU in the current era of high-activity antiretroviral treatment

P Vidal Cortés, V Aller Fernández, M Maurelo Faríña, P Lameiro Flores, P Vázquez Rodríguez, A Castro Iglesias

CHU A Coruña, A Coruña, Spain

**Introduction** Our purpose is to study the effect of high-activity antiretroviral treatment (HAART) on the epidemiology and outcome of human immunodeficiency virus (HIV) patients in the ICU. HAART has modified the outcome of patients infected with HIV, increasing survival and reducing infectious complications. In the first years of HAART use a significant change in the diagnosis and prognosis of ICU-admitted HIV patients has been identified, but there are no studies investigating this issue in the most recent years.

**Methods** A retrospective study. HIV patients admitted to a 36-bed ICU, between January 2005 and December 2009 (HIV incidence in our population: 42 cases/million hab/year). We studied demographic characteristics, having or not HAART, final diagnosis, need for organ support and outcome (length of stay (LOS) and mortality).

**Results** One hundred and five HIV-infected patients (70.5% being male), 52 (49.5%) having HAART. Mean age: 41 ± 8.57 years. More common co-morbidities were: hepatic disease (61%), cirrhosis in a 10.5%, followed by chronic respiratory disease and dyslipemia (12.4%), cardiac disease (5.7%), solid and hematologic malignancy (5.7% and 2.9%, respectively). A total 70.5% had a history of intravenous drugs use, and 13.3% were heavy alcohol consumers. Average CD4 count was 275.4 ± 362/ml, mean viral load was 3,656 ± 3,000/ml. A total 52.1% were on their CD4 nadir at admission time. Most frequent final diagnosis (grouped): infectious disease, 58.3% (focuss: lung 66.7%, CNS 16.7%), cardiac disease (12.7%), intoxication and trauma (5.8% each one). Average APACHE II: 20.9. A total 48.6% of patients needed support with vasopressors, 64.7% mechanical ventilation and 15.2% renal support. A total 69.5% of patients needed at least one organ support. ICU LOS: 8.7 ± 9.9 days, hospital LOS: 29 ± 29.5. ICU mortality: 28.6%, hospital mortality: 35.2%.

**Conclusions** Despite the beneficial effects of HAART on immune status, infection (especially pneumonia) remains the most common cause of ICU admission. Our results confirm the trend to a lower mortality saw in early HAART period studies.

Clinical characteristics and outcomes of obstetric patients requiring ICU admission

H El-Abd, K Mashhout, A Mwafy

Cairo University Hospitals, Cairo, Egypt

**Introduction** Despite therapeutic advances during this century, maternal mortality remains an important public health problem. So it was logical to study these patients who were referred from the Gynecology and Obstetric Department to our ICU aiming to review a series of these patients in order to assess the spectrum of diseases, required interventions, complications that occurred and maternal mortality and to identify conditions associated with maternal death.

**Methods** A retrospective cohort study in the Critical Care Medicine Department, Cairo University. The medical records of all obstetric ICU admissions over the period from January 2005 to December 2009 were reviewed.

**Results** Over these 5 years, 169 women required ICU admission (1.6% of all ICU admissions). The mean age was 29.29 ± 6.06 years; mean gestational age was 34.56 ± 3.01 weeks, and the mean length of ICU stay was 3.32 ± 3.6 days. Most patients (77%) were admitted with obstetric cause, the most common cause of maternal morbidity was pregnancy-induced hypertension (56.21%), followed by obstetric hemorrhage (17.75%). Heart failure (13.6%) was the principal nonobstetric cause. Maternal mortality rate was 4.14%, with hypovolemic shock and MODS (71.4%) as main causes. Despite the incidence of death being higher among patients with obstetric versus nonobstetric cause (4.6% and 2.6%, respectively), this was not statistically significant (\( P = 0.91 \)). Twenty-five percent of patients had prior medical diseases, 76.74% of them had cardiac problems. The most common interventions were central venous catherization (91.1%), endotracheal tube intubation (16.6%), and mechanical ventilation (12.4%). Disturbed conscious level, MODS, shock, ARF, bleeding, and ARDS were present in 17.8%, 12.4%, 10.7%, 10.7%, 8.9% and 7.1% of patients, respectively. Anemia, leucocytosis, and trombocytopenia were more present in the obstetric group.

**Conclusions** The admission rate to the ICU may be reduced by improving the management of the hypertensive disease during pregnancy. Early admission to the ICU decreases the maternal mortality and morbidity. Despite several complications occurring with obstetric patients, the prognosis is still good.

Management and risk factors for maternal morbidity of eclampsia in a Moroccan teaching hospital

Y Zarrouki, M Boutaoubou, Y El Waggaqi, G El Adib, S Ynoun

Mohammed VI Teaching Hospital, Marrakesh, Morocco

**Introduction** Eclampsia is a serious complication of pregnancy, it remains a frequent condition in our context. The aim of this study is to measure the incidence of eclampsia, its risk factors associated with adverse maternal outcome and to identify its most common presentations in our practice.

**Methods** Through a prospective descriptive study spread over 1 year (November 2009 to October 2010), all cases of eclampsia gathered in the maternity ICU of Marrakesh Teaching hospital were included, and epidemiological and prognostic data were analyzed by either chi-squared analysis or the unpaired Student test as appropriate.

**Results** The incidence of eclampsia was 6.68/1,000 deliveries, it is behind 11% of hospitalizations in our ICU (59 cases during study period) with 87% of patients referred from all southern Morocco. Sixty-two percent of seizures occurred antepartum, 20% during labor and 18% postpartum. Two peaks of age are observed, 22 ± 5 years and 36 ± 4 years. Major maternal complications included HELLP syndrome (12%), abruptio placentae (8%), disseminated intravascular coagulopathy (8%), pulmonary edema (5%), acute renal failure requiring dialysis (4%), aspiration pneumonia (3%) and neurologic complications (3%) including hemorrhage, ischemia and cerebral venous thrombosis. Maternal mortality was 6.7% and perinatal mortality was 16.9%. Parturients with antepartum eclampsia have significantly higher incidences of HELLP syndrome (14% vs. 6%; \( P = 0.02 \)) and abruptio placentae (12% vs. 4%; \( P = 0.006 \)) than did those in whom eclampsia developed intrapartum and postpartum. In contrast, women with postpartum eclampsia were more unlikely to have acute renal failure.
P515 Clinical and diagnostic value of transcranial cerebral oximetry in the optimization of mechanical ventilation in newborn infants

V Estrin, A Simonova
Research Institute of Obstetrics and Pediatrics, Rostov on Don, Russia

Introduction Treatment of ischemic damage to organs and tissues by mechanical ventilation with a high content of oxygen in the inspired mixture (FiO₂) can lead to oxidative stress and reperfusion of tissue alteration, which is particularly characteristic of infants with their characteristic low levels of antioxidant protection. From this perspective, there is optimal mode selection in mechanical ventilation, and FiO₂ of vital organs and tissue, namely in brain tissue, which was made possible through the use of transcranial cerebral oximetry (TCO).

Methods At stage 1 of the study, with the consent of the ethics committee and informed parental consent, we examined 24 infants born in the physiological department of the maternity hospital RNIIAP of gestation 38 to 40 weeks, with Appgar 7 to 10, and birth weight 2,500 to 3,900 in the state of physiological sleep after feeding. In all children, we measured the cerebral tissue oxygen saturation (SctL, SctR) using the cerebral oximeter Fore-sight (USA) at 1, 3 and 5 days after birth. Later, in a controlled, randomized study were included two groups of neonates on mechanical ventilation. In patients of group 1 (n = 35), modes and ventilator FiO₂ were determined under the control of TCO in a way that is as close as possible to indicators of cerebral oxygenation for the age norm. In patients of group 2 (n = 33), mode selection and FiO₂ ventilation was carried out under the supervision of pulse oximetry and partial oxygen tension (pO₂), according to acid–base balance, excluding indicators for TCO.

Results At stage 1 the study defined age-norm TCO indicators for healthy infants amounting in the left hemisphere of the brain to 79.2 ± 4.06% (0.01 < P < 0.05) and in the right hemisphere to 84.89 ± 5.1% (0.01 < P < 0.05). At phase 2 of the study group infants, the selection of modes and ventilator FiO₂ on the basis of indicators for TCO statistically significantly (in all cases 0.01 < P < 0.05) decreased length of stay on the ventilator (from 9.4 to 5.6 bed-days), mortality (from 2.7% to 0.6%), and number of complications (cases of radiologically confirmed pneumonia from 4.2% to 0.2%) compared with the control group.

Conclusions The use of TCO for the optimization of mechanical ventilation and oxygen saturation monitoring in brain tissue in newborn infants in critical condition is a promising method for reducing mortality, reducing the term of ventilation and reducing complications of oxygen therapy in this group of patients.

P516 Assessment of artificial ventilation in Salvadoran public hospitals

JF Granados, PE Sobenes, MT Bertalli
Dr. Jose Mano Delgado University, Antiguo Cuscatlan, El Salvador

Introduction Artificial ventilation (AV) is an essential resource that is not always available at Salvadoran public hospitals. Approximately 40% of hospital-related deaths may have required AV [1]. The main indication for AV is respiratory insufficiency requiring support for these patients. Variations in ventilation modality and time among others can affect patient health [2]. The aim of this study was to clarify the AV situation in national hospitals of El Salvador’s public health system.

Methods This study is transversal descriptive. A representative sample (n = 5) of public national hospitals was selected. These included four second-level hospitals and one third-level hospital. Two hospitals were from the central metropolitan region, one from the par central, west and east region; representing 36.1% of available hospital beds nationwide. To complete AV data of the totality of public hospitals, a telephone survey was used. All data about patients, AV type, costs, maintenance and operative personnel, among others, were collected.

Results Only 18% of all public hospitals around the country have mechanical AV. The majority of mechanical AV on the public health network is focused on Rosales National Hospital (HNR), with 61.9% of mechanical ventilators nationwide. Mechanical AV is operated by respiratory therapy personnel at HNR and Zacamil National Hospital; however, in another two hospitals from the east and west region, mechanical AV is operated by residents; and manual AV is provided by self-inflating resuscitator bag operated by interns only. The main causes of AV are nonsurgical; representing 88.9% of the reasons to employ mechanical AV, and 100% for manual AV. The mean patient ventilation time for mechanical AV was >48 hours, and for manual AV was >24 hours. No patient with manual AV had normal pO₂. The maintenance cost for all mechanical AV was less than $100 per month per ventilator and only 68% of mechanical ventilators were functional, the most frequent model being Servo900.

Conclusions The actual mechanical AV existence is very limited, since only four out of 14 departments have this resource, representing 18% of public health centers nationwide. Mechanical AV is centralized in the department of San Salvador, leaving 82% of these centers with no mechanical ventilation at all, being probably supplanted by manual AV. Results show the necessity for cheaper, efficient and easy-to-use AV systems.

P517 Comparison of the stated religious beliefs amongst UK intensive care physicians and the UK population

A Tillyard, DT Ashton-Cleary
Derriford Hospital, Plymouth, UK

Introduction The UK is a multi-faith culture and 77% of the population considered themselves to belong to a religious group in the 2001 UK Census [1]. Differences in faith have differing customs and views surrounding end-of-life decisions and care. Treatment withdrawal and withholding of life-sustaining care or CPR have been shown to be significantly influenced by both patient and physician religion [2]. We wanted to determine whether the population faith mix was reflected in intensive care physicians.

Methods We conducted an online survey amongst the members of the UK Intensive Care Society. We asked them to state whether they considered themselves to belong to a faith group.

Results A total of 550 questionnaires were returned; 182 (33.1%) were from intensive care consultants. These are compared with UK 2001 Census data. Over 50% abstained from the question (vs. 7.8% in the Census). A total 11.8% of respondents were atheists (vs. 15.0% in the Census). Members of the Catholic Church and Church of England formed 8.4% and 10.2% of respondents. These faiths are grouped together in the Census as Christians and formed 71.8% in that sample. A total 1.8% were Hindu (0.98% in the Census) and 1.5% were Muslim (vs. 2.78% in the Census). Those belonging to other faiths formed 14.5% amongst respondents and 1.59% in the Census.

Conclusions The proportionately smaller UK faith groups are represented to largely similar extents amongst physicians. A much larger proportion of our study sample abstained from the question than in the UK Census (51.8% vs. 7.8%). Our questionnaire was presented along with queries regarding decisions to exclude patients from the ICU; abstainers may have felt their religious beliefs were being unfairly judged as a source of bias in their other answers. The religious makeup of a group of physicians can clearly not be manipulated to match that of the population but consideration should be given to how this factor may influence treatment decisions. This is likely to be of particular relevance where physician and patient do not share the same faith.

PS18 Characteristics of Outreach patients that received end-of-life counseling
K Kyeremanteng, RP Patel, EF Fitzgibbon
The Ottawa Hospital, Ottawa, Canada

Introduction Approximately 20 to 30% of ICU patients are palliated in the ICU. Many of these patients have not had goals of care discussions prior to being admitted to the ICU. Several of these patients may have prolonged courses that can cause anguish for patients and their families and may have been prevented if goals of care discussions occurred earlier. There has been increasing evidence that palliative care involvement in critical care improves outcomes such as quality of end-of-life care [1], decreased length of stay [2] and better pain and symptom management [3]. No studies have looked at medical emergency teams/Outreach with respect to palliative care and end-of-life care. We performed a retrospective descriptive study looking at the characteristics of Outreach patients who received end-of-life counseling (EOLC).

Methods We evaluated 80 patients from The Ottawa Hospital General campus that were seen by Outreach and received EOLC in 2007. From the Outreach database and the hospital computerized health record system, we obtained patient demographics and medical information such as admission diagnosis and reason for Outreach call. We compared these patients with ones that did not receive EOLC. We also subdivided the patients that received EOLC into patients that were successfully palliated versus ones that were not palliated and compared patient characteristics.

Results Twenty-one percent of all Outreach patients received EOLC in 2007. Comparing patients that received EOLC with those with no EOLC, mean age was 72.3 ± 11.5 versus 68.9 ± 17.6 (mean ± SD). Fifty-two percent had cancer versus 38%. Dementia was involved in 17% of EOLC patients versus 8% in non-EOLC patients. Length of stay (LOS) was 26.3 ± 26.1 days versus 34 ± 30.7. Admission to Oncology/Hematology/Radiation Oncology was 33% in the EOLC group compared with 20%. The proportion of patients seen during the day was 49% versus 64%. Call indication was mostly respiratory in the EOLC group (53% vs. 32%). Sex, number of co-morbidities, days admitted prior to Outreach call and admission diagnosis were similar in both groups. Amongst the patients that received EOLC, 49% were palliated and 51% were not palliated. Patient characteristics were similar in these two groups. (P Score testing is pending.)

Conclusions At our tertiary center, the Outreach patients that receive EOLC tend to be older, admitted for respiratory illness and have a diagnosis of cancer.

PS19 Discussing end-of-life issues with terminally ill cancer patients and their families: our results
BE Efthimova, B Lazarova
Clinical Hospital, Stip, Macedonia

Introduction Most of the literature regarding communication between health professionals and patients at the end of life and their families has focused on specific topics, like breaking bad news and discussing treatment decisions such as CPR and advanced directives. Conversation about end-of-life issues often takes place over time rather than as a single discussion. The objective of this paper is to explore the optimal content and phrasing of information when discussing the dying process and E-O-L issues with terminally ill cancer patients and their families.

Methods We conducted focus groups and individual interviews with 20 palliative care patients and their families treated in Clinical Hospital Stip in the past 12 months. The focus groups and individual interviews were fully transcribed. Further individual interviews were conducted until no additional topics were raised. Participant’s narratives were analyzed using qualitative methodology.

Results Distinct content areas emerged for discussing E-O-L issues; treatment decisions at the E-O-L; potential future symptoms; preferences for place of death; the process of dying; what needs to be done immediately after death; and existential issues. When discussing process of dying participants are recommended: exploring the person’s fears about dying; describing the final days and unconscious period; and the reduced need for food and drinks. Many participants identified the dilemma regarding whether to discuss potential complications around the time of death.

Conclusions This paper provides strategies, phrases and words that may inform about the process of dying and E-O-L issues. This will be useful especially for patients’ families. Further research is needed to determine the generality of these findings.

PS20 Factors associated with withdrawal of life-sustaining therapy in severe traumatic brain injury patients
N Côté1, A Turgeon1, F Lauzier1, L Moore1, JF Simard1, D Scales2, K Burns2, M Meade3, F Bernard1, D Zygyn1, D Ferguson1, Canadian Critical Care Trials Group
1Université Laval, Québec, Canada; 2University of Toronto, Canada; 3McMaster University, Hamilton, Canada; 4Université de Montréal, Canada; 5University of Calgary, Canada; 6University of Ottawa, Canada

Introduction Traumatic brain injury (TBI) mortality remains high and often follows withdrawal of life-sustaining therapy (WLST). Studies reporting the determinants of WLST in this population are scarce. We analyzed data from a multicenter retrospective cohort study to identify factors associated with WLST in TBI.

Methods We randomly selected charts of 720 mechanically ventilated severe TBI patients (identified using ICD-10 codes) admitted to the ICUs of six participating centers (120 patients per center) over a 2-year period. Data were abstracted using a standardized case report form and operations manual. Among nonsurvivors (n = 228), we compared patients who died following WLST with those who did not in order to investigate the potential influence of variables pertaining to the injury and management. Our final model to WLST included four baseline characteristics (age, gender, GCS and pupillary reflex) and factors with P <0.2. Research ethics approval was obtained in all participating centers.

Results We analyzed 225 patients (three missing data) including predominantly male patients (69.7%) with a mean age of 50.7 years. Among nonsurvivors, brain herniation on initial CT scan was more often reported in patients dying following WLST (OR = 2.91, 95% CI = 1.16 to 7.30, P = 0.02), while the opposite was observed for epidural hematoma (OR = 0.18, 95% CI = 0.06 to 0.56, P <0.01). Craniotomy (OR = 0.12, 95% CI = 0.02 to 0.68, P = 0.02) and other non-neurosurgical procedures (OR = 0.08, 95% CI = 0.02 to 0.43, P <0.01) were associated with a lower odds of death following WLST. Other interventions, such as vasopressor use (OR = 0.50, 95% CI = 0.22 to 1.11, 15(Suppl 1)).
Documenting end-of-life care plans on the ICU: using a digital proforma may improve compliance with nationally agreed standards
S Cantellow, D Harris, S Smith, C Bordeaux, M Thomas
Bristol Royal Infirmary, Bristol, UK

Introduction The Liverpool Care Pathway (LCP) is the accepted gold standard in the documentation of end-of-life care in the UK. A computerized version of the LCP in the form of a digital proforma (DP) exists as an option on our unit. Some clinicians choose to use free-text (FT) entry citing this can be more comprehensive. Our study investigates whether usage of the DP is likely to result in a greater degree of compliance with LCP standards than FT alone.

Methods All deaths occurring between 1 January 2009 and 30 June 2009 were identified from the record of ITU admissions. Cases of cardiac arrest and brain stem death were excluded. Quality of documentation was scored by a nurse and doctor assessor (for each LCP goal: 0 = nothing entered, 1 = goal partially addressed, 2 = goal fully addressed). The average of the total scores for each case was calculated. Performance of the DP was analysed by comparing average total scores for DP versus FT alone using simple non-parametric descriptors.

Results There were 52 deaths and 45 after exclusions. Use of the DP resulted in considerably higher total average scores (range 13.50 to 17.5. interquartile range 15.50 to 16.75, median 15.50) than use of FT alone (range 0.00 to 9.50, interquartile range 1.75 to 6.25, median 4.00). Statistical significance is suggested by the lack of overlap in the range values. See Figure 1.

Conclusions Using the DP for end-of-life documentation is highly likely to improve compliance with accepted standards in end-of-life care. Doctors using FT alone were unlikely to document all of the broad issues that require consideration. The use of a DP can function as a useful checklist ensuring patients receive the best care when organ support is withdrawn.

Figure 1 (abstract P521).
Doppler (TCD) and 12 to evoked potentials (EPs). Twenty-three centres had used or would consider ancillary tests in addition to clinical tests where these could not be completed due to the nature of injury (for example, facial trauma); 19 centres had used or would consider this when drug levels were unavailable. Four centres had used ancillary tests alone to confirm BSD where depressant drug levels had precluded clinical testing; a further eight centres would consider this approach. First-choice investigation was CTA in 48% of centres, 30% preferred 4VA, and 4% TCD. Following cessation of sedative drugs, there was considerable variation in timing of clinical testing and pharmacokinetic factors considered. Whilst 33% of centres measure thiopentone levels in all cases, 22% never do. In five centres, delays in testing due to raised drug levels exceeded 5 days. Where raised levels preclude testing, 17 centres were confident that 4VA would diagnose BSD in some or all circumstances; 13 centres were confident with CTA. TCD and EPs were considered less reliable.

Conclusions There is considerable variation in UK opinion and practice. Measurement of drug levels is not universal but raised levels delay diagnosis significantly. More than one-half of the centres surveyed would be confident in using an ancillary test alone to diagnose BSD. Further consensus is needed.

Children visiting the ICU

KK Borges, L Genaro, M Monteiro
 Clinica Sao Vicente, Rio de Janeiro, Brazil

Introduction Most hospitals only allow children above 12 years old to visit adult ICU patients. However, younger children participating in the hospitalization process manifest, through their family members, their willingness to visit their hospitalized relatives. This raises different healthcare team members' opinions on how to manage their visits to the ICU and prevent psychological harm. This study suggests some relevant steps to allow and receive a child in an adult ICU.

Methods A literature review on children visiting the ICU was performed to construct the steps. The flowchart was based on Torres' studies of the child in the face of death, based on Piaget's cognitive development. The flowchart: Identify the family request, either to the psychologist or to the team, to allow the child's visit / Understand the family context and information provided to the child / Healthcare team discussion – team consensus and ICU routine adjustment / Psychologist interview and accomplishment to the bed / After-visit evaluation and follow-up during the ICU stay from family information.

Results The literature search has shown diversified results. The use of the flowchart, adjusted to each case requirement, has been very useful in our institution's practice. We could perceive that the healthcare team feels more serene and confident with this guidance and that the families feel more relieved and assured by sharing their afflictions related to their children.

Conclusions The interdisciplinary work is fundamental to using the flowchart, requiring a healthcare team aligned with its aims and, above all, sensitive to the essence of the bioethical principal of autonomy, ruled by the patient's and family member's will. However, due to this subject relevance and sensitivity, new discussions are required to deepen the studies and therefore systematize children's visits to ICUs.

References
was generally good. The relatives of the survivors were more satisfied in all dimensions evaluated (a value closer to greater satisfaction), although this difference was statistically significant only in the comfort dimension (P = 0.003).

Conclusions Contrary to other studies we found that relatives of the survivors are more satisfied with most aspects of care received, better meeting their needs than family members of nonsurvivors, although this difference is statistically significant only in the dimension comfort. The results emphasize the need for improved measures of comfort in the ICU. One factor, among others, to explain this result may be that on one hand the aspects of patient-centered care and family were similar in both groups, but on the other hand the relatives of the survivors feel more a lack of space suitable for families that currently do not exist in our ICU. There is a growing recognition that families are an integral part of the modern ICU and that we should incorporate the findings of this evaluation of needs and family satisfaction in quality improvement in the ICU.

Patient’s families in the ICU: describing their strategies to face the situation
KK Borges, MG Mello, CM David
Universidade Federal do Rio de Janeiro, Brazil

Introduction The ICU is an environment that generates permanent anguish in family patients due to the possibility of the death of the patient [1]. The stressful situation might induce families to call upon strategies of facing different levels and intensities to keep the harmony of its own emotional structure. The objective is to describe the strategy processes used by families of severely ill patients in the ICU to face the situation.

Methods A prospective study covering 14 families. We applied a qualitative method of interviewing and observing participants, complementing the data-gathering by applying the Strategies Inventory of Coping, by Folkman and Lazarus, adapted by Savoia and colleagues [2]. The mixed method used to interpret the results combines the quantitative and qualitative data into only one phase of the study, prioritizing the descriptive-analytical logic. Among the criteria of inclusion are: one member of the patient family in the ICU for more than 1 week, being an adult, must be present in most of the visit periods and receiving physician’s information of the patient conditions.

Results Families utilize diverse strategies and at different levels, but the most used strategies almost always and most of the time are: escape and avoid (93%), positive re-evaluation and a strategy of problem-solving (79%), social support (43%) and responsibility acceptance (7%).

Conclusions The stressful situation might induce families to call upon strategies of facing different levels and intensities to keep the harmony of its own emotional structure. The objective is to describe the strategy processes used by families of severely ill patients in the ICU to face the situation.

Communication with relatives in the ICU
M Liu, S Hutchinson
Norfolk & Norwich University Hospital, Norwich, UK

Introduction Relatives of patients in the ICU undergo considerable stress. Effective communication with relatives has been shown to: provide support, reduce stress, and improve their well-being and decision-making. Satisfaction also depends on communication by a senior caregiver. Our aim was to determine how well relatives of patients in the Norfolk & Norwich University Hospital (NNUH) ICU are kept informed.

Methods The Metavision® Clinical Information System is used for documentation at the 20-bed NNUH ICU. Retrospective data analysis was conducted for patients staying >4 days during 1 October 2009 to 1 January 2010. Data from the ‘Relatives Communication’ page included: how often and when relatives were first spoken to, and the staff involved. Thirteen variables were compared with patient outcome and length of stay on the ICU. During 1 August to 1 October 2010 relatives were asked to anonymously complete a survey evaluating consultations in the ICU.

Results Of 64 notes, communication with relatives was documented in 55% of patients. Of these, 60% of communication was conducted by a consultant. More discussions occurred with relatives of patients who died. Increasing duration of stay on the ICU resulted in a higher percentage of relatives being spoken to. Sixty-seven per cent of relatives of patients staying >20 days were not communicated with until after day 4 of admission. Of 40 surveys, all relatives agreed that the patient’s condition was discussed with them quickly enough after admission. Ninety-three per cent agreed that they were spoken to often enough and 95% felt by the right staff. Eighty per cent were spoken to by senior staff but 45% stated updates were mostly given by nursing staff. Ninety percent felt they were given the right amount of information and in an appropriate location. Ninety percent were satisfied with their consultations. Seventy-three per cent agreed or partially agreed that written information about critical care would have been helpful.

Conclusions Analysis of the notes indicated that communication with relatives of patients on the ICU was poor. This prompted surveying relatives’ satisfaction directly, which found that most are satisfied with their experiences of communication in the ICU. Hence, we conclude that relatives are well informed – mainly by nursing staff – but documentation of communication requires improvement. The system currently favours recording of formal conversations by medical staff whilst nursing updates are often documented elsewhere. A solution may be to develop a multidisciplinary record of communication.

Inter-observer agreement of Medical Research Council-sum score and handgrip strength in the ICU
G Hermans, B Clerckx, T Vanhullebusch, J Segers, G Vanpee, C Robbeets, M Casaer, P Wouters, R Gosselink, G Vandenberghe
UZ Leuven, Belgium

Introduction Muscle weakness often complicates critical illness and is associated with prolonged duration of rehabilitation, increased mortality and limiting functional outcome even years later [1]. To examine the effects of interventions on this complication, reliable measurements of muscle force in critically ill patients are needed. We aimed to examine, in critically ill patients, the inter-observer agreement on the Medical Research Council (MRC)-sum score and handgrip strength, two methods to quantify muscle force.

Methods All patients were included in an ongoing randomized controlled trial examining two feeding strategies (ClinicalTrials.gov: NCT 00512212) and constituted a cross-sectional, randomly selected sample. Patients were studied on median ICU day 17 (11 to 29.5). Two observers independently measured the MRC-sum score in 75, and handgrip strength in 46 critically ill patients.

Results The intra-class correlation coefficient (ICC) for the MRC-sum score was 0.95 (0.92 to 0.97), with weighted kappa coefficient for individual muscle group scores of 0.83 ± 0.03. Kappa coefficient was 0.68 ± 0.09 for identifying patients with MRC-sum score <48, 0.88 ± 0.07 for MRC-subtotal in the upper limbs <24, and 0.93 ± 0.07 for...
MRC-sum score <36. The ICCs for left and right handgrip strength were respectively 0.97 (0.94 to 0.98) and 0.93 (0.86 to 0.97).

Conclusions We found very good inter-observer agreement, both for MRC-sum score and for handgrip strength in critically ill patients. When applying MRC-sum score <36 as a cut-off for severe weakness, agreement was excellent supporting its use as an outcome parameter for interventional studies. Agreement on identifying significant weakness (MRC-sum <48) was good. For an equivalent cut-off to identify significant weakness in the upper limbs (<24), agreement was very good. It remains to be determined whether this may be used as a substitute for the total MRC-sum score.

Assessment of functional capacity after discharge from the ICU
E Caser, P Simões, A Casati, C Barbosa
CIAS, Vitória, Brazil

Introduction Functional capacity refers to the degree of involvement in activities and is often used as synonymous with performance in activities of daily living such as self-care. These measures of capacity are useful and provide some understanding on the prognosis and outlook for independence after discharge. This study was designed to analyze the functional capacity before ICU admission and after hospital discharge.

Methods A 7-month prospective observational study (1 October 2007 to 1 May 2008) was carried out in a 16-bed medical–surgical ICU. Patients >18 years old and admitted >72 hours were included. We interviewed cooperative patients or close relatives using the Barthel Index to evaluate the ability of a patient in daily life activities. Questions were applied upon admission to the ICU and 7, 90 and 180 days after hospital discharge.

Results Out of 322 admissions, 135 patients met trial criteria for inclusion in the study (mean age 66 ± 22 years and 55.6% male). The mean APACHE II score was 18 ± 6 and the mean length of ICU stay was 17 ± 7 days. A total of 15.9% were ached at admission, 39.1% at 7 days, 23.9% at 90 days and 28.3% at 180 days after discharge were still ached. Upon admission 43.5% practiced some type of physical activity, 7 days after discharge 21.7%, and at 90 and 180 days 40% and 34.8%, respectively, had some physical activity. The functional capacity assessed by the Barthel index at admission, 7, 90 and 180 days after hospital discharge were respectively 84 ± 28, 71 ± 32, 78 ± 31 and 79 ± 31 points. There was a statistically significant difference between functional capacity at baseline, at 7, 90 and 180 days with APACHE II and age. The ICU mortality was 14.4%, hospital mortality was 31.9% and cumulative mortality at 7 days after hospital discharge was 32.6%, at 90 days was 36.3% and at 180 days was 38.5%.

Conclusions The independence in daily life activities decreased significantly after admission to the ICU; however, at 90 and 180 days after hospital discharge they increased but did not return to their levels prior to admission. The presence of an ill population of older people in the ICU may have contributed to these results.

Rehabilitation after critical care: using audit to guide changes in practice, a multidisciplinary (MDT) approach
N Glasy, E Blake, D Green
Kings College Hospital, London, UK

Introduction To audit the holistic assessment and treatment planning of critical care patients of more than 5 days stay, in line with the National Institute of Clinical Excellence (NICE) guidelines published in March 2009. The guidelines state that each patient should have a full comprehensive assessment and reassessment of all physical and nonphysical potential problems, individual goal-setting and documented communication between patient, MDT and family members.

Methods An audit form was developed from NICE guidelines and piloted with 10 patients, feedback on the audit form from the staff was then collected and the audit form amended as necessary. A sample of patients was identified (10% of 2008/2009 admissions of >5 days) and the first 10 sets of notes were assessed for inter-rater reliability between the staff collecting the information (doctors, occupational therapists, physiotherapists, nurses and speech and language therapists). The results were then compiled and new documentation developed to prompt consideration of potential physical and nonphysical problems. Weekly MDT rehabilitation ward rounds and goal-setting meetings were also commenced. A repeat audit using the same tool is to commence in December 2010/January 2011 with a second sample planned for June 2011/July 2011 in line with original audit samples.

Results Physical problems were comprehensively assessed in 100% of the sample population; however, there was little evidence of assessment of potential nonphysical problems in most patients. There was poor documentation of information-giving to patient relatives in all aspects of their care, particularly around goal-setting and social aspects of care. Transition from critical care to the ward was highlighted as an area to be improved, with poor information provision to the ward and to the patient/carer.

Conclusions Following the initial audit, in order to resolve the highlighted issues several initiatives were put in place: a rehabilitation ward round was commenced with weekly MDT goal-setting, a psychosocial history form was introduced along with a critical care MDT assessment tool. We are now beginning to re-audit following these changes in practice. Subjectively, collaborative working has enhanced patient care by optimising communication across the whole MDT. At the time of the conference 50% of the second audit will be completed, which will give some indication of the impact of our change in practice.

1. [www.guidance.nice.org/CG83]
Conclusions All patients leaving our ICU received the required standards of assessment with regards to their rehabilitation needs. A more robust system is required to ensure referral to a psychologist when indicated, as anxiety and depression following ICU admission is reported in up to 40% of patients [1]. A patient leaflet explaining these risks and the benefits of attending ICU follow-up clinics may improve outcomes.

Follow-up after critical care
M Slattery, P Templett, A Houghton, D Hope
ABM University Trust, Swansea, UK

Introduction Many patients experience physical and psychological morbidity following a stay in critical care [1]. The National Institute of Clinical Excellence (NICE UK) recommends access to follow-up and rehabilitation services for this patient group [2]. We aim to present 1 year’s experience following the establishment of a follow-up service at our university teaching hospital.

Methods The multidisciplinary follow-up team consisted of a consultant in critical care, a senior nurse and a critical care physiotherapist. Patients completed a preclinic questionnaire followed by a semi-structured interview to identify potential issues. Twenty-four clinics took place over the 12-month period.

Results A total of 221 patients were recruited. Of the patients studied 26% attended the clinic and completed the evaluation questionnaire, 30% did not engage follow up services. We identified recurrent themes in both physical and nonphysical problems. Example physical problems include limited physical activities in 77%, with 54% of patients studied finding difficulties with activities of daily living. Alteration in taste, smell, hearing and vision modalities was frequently described. In terms of psychological morbidity, anxiety and post-traumatic stress symptoms seem to predominate. Significant numbers of patients retain memory of their ITU stay, with one-third in the form of flashback memories. Only 5% of patients studied returned to work.

Conclusions Our findings demonstrate that a wide variety of problems can be identified in an ICU follow-up clinic. The challenge now is to identify those groups of patients who will benefit most from follow-up, to develop effective rehabilitation programmes for these patients, and to find methods to increase patient participation.

Sunlight exposure does not influence ICU survival
R Castro, S Hong, C Lee, L Weissfeld, G Clermont, D Angus, M Rosengart
University of Pittsburgh Medical Center, Pittsburgh, PA, USA

Introduction The biological influence of light on human physiology (for example, circadian rhythms, cortisol and melatonin) has long been recognized. Recent interest has been directed to understanding the ramifications of light on immune function, particularly in the context of patient care. Although light and seasonal variations have been shown to modulate leukocyte count and lymphocytes B and T activity and proliferation in mammals, little is understood about these interactions in the course of illness. Thus, we hypothesized that sunlight is directly associated with improved outcome in critically ill patients.

Methods We conducted a retrospective, cohort study of all patients admitted to the ICU at a single center between the years 2000 and 2004. Light exposure was assessed by theoretical insolation (kWh/m²/day), a measure of solar energy striking a unit of earth surface area that was obtained from the National Aeronautics and Space Administration. Daily and total insolation was determined for each patient, accounting for hospital geographic location, period and duration of hospitalization, and adjusted by day-specific admission/ discharge–sunrise/sunset times. To adjust for differences in case mix, we abstracted data regarding patient age, race, injury severity score, length of stay (LOS) and admission diagnostic categories. Patients who died before 24 hours were excluded from the analysis. The hypothesis was modeled using a multivariate logistic regression submodel for survival and a linear mixed submodel for the mixed measurement. Both were linked by the random intercept parameter in the mixed submodel.

Results A total of 22,730 patients were available for study. The majority was male (52.7%) and Caucasian (80.0%) with a mean age of 59.4 ± 17.7 years. The leading ICU admission diagnoses were cardiovascular conditions (23.4%), trauma (13.4%) and sepsis (5.9%). The mean APACHE III score was 52.8 ± 28.3, LOS was 3.3 ± 2.3 days and mortality was 13.4%. The total insolation per patient was 14.8 ± 33.2 kWh/m² (mean ± SD). After adjusting for differences in case mix, there was no significant association between survival and total insolation dose at 24 hours and up to the 10th day of ICU hospitalization (P = 0.64). A tendency towards lower mortality with higher insolation was observed for trauma patients (P = 0.15), although this did not attain statistical significance.

Conclusions Sunlight has no impact on general ICU patient survival according to our analysis. In other relevant outcomes (mechanical ventilation requirements, sedation, delirium incidence, and so forth), the impact of sunlight still has to be elucidated.

P535
Incidents related to intrahospital transport of patients in the ICU
C Van Velzen, AH Brunsweld-Reinders, MS Arbous
Leiden University Medical Center, Leiden, the Netherlands

Introduction The objective of this study was to determine the incidence and type of incidents related to intrahospital transport (IHT) of critically ill patients in our ICU and to identify contributing factors of these incidents.

Methods Since 2006 an electronic incident registration system was implemented on our tertiary university mixed adult ICU. Two investigators identified incidents related to IHT between 2006 and 2009. IHT incidents were categorized according to phase of occurrence: before, during or after IHT. The physical derangement of the patients could be cardiovascular, respiratory, or neurologic. By means of a structured incident analysis method, potential causal and contributory factors were determined.

Results In a 1-year period (2009) 568 transports were performed in 1,821 ICU patients. Thus about one-third of all ICU patients needed IHT. Of all incidents reported from 2006 to 2009, 2.1% was IHT related. IHT had an incident rate of 3.7%. Of all IHT incidents (n = 124), 35% occurred pre-transport, 50% during transport and 15% post-transport. Thirty-two patients (25.8%) had a physical derangement. The most common causes of IHT incidents were coordination errors (n = 31), human error (n = 39), organizational (n = 50) and equipment failure (n = 86); more than one cause per case could be assigned. The physical causes of the incidents were cardiovascular (n = 39), respiratory (n = 28) and neurological (n = 2). Contributing factors were mostly equipment related (n = 22). Human error was divided between during transport (n = 33) and pre-transport (n = 33) and fewer occurred after transport (n = 18). Contributing factors were coordination errors (n = 37) and external factors (n = 19). Organizational causes were mostly pre-transport (n = 26) and during transport (n = 20) and fewer after transport (n = 4). Almost all contributing factors were due to information transfer (n = 31). Overall, the most important contributing factors were coordination errors (n = 37), information transfer (n = 31), equipment failure (n = 22), and insufficient supervision (n = 22).

Conclusions Incidents related to IHT have an incidence of 3.7%. Most incidents occurred pre-transport and during transport. The incidents occurred after transport (n = 2)

Discussion The findings are comparable to those of other studies [1,2]. In our patient population some high-risk factors for IHT incidents were identified (n = 31). The risk profile of these incidents was not different from those at the national level [2]. In contrast to our findings, van der Bijl et al. found that coordinator error was the main cause of IHT incidents [3].
are predominantly on the respiratory and cardiovascular systems. Human failure is an important cause of IHT. Contributing factors were coordination errors, equipment failure, information transfer and insufficient supervision. Given the contributing factors we think the number of incidents could be reduced by means of a transportation checklist.

**Results**

**P537**

Trials are larger, more frequently originate from North America, and time; a minority of these is fully funded by industry. Industry-funded industry-funded RCTs, but has remained relatively constant for non-RCTs. Studies investigating drug interventions increased over time. Reporting of Data and Safety Monitoring Board involvement also the Mann–Whitney U test, t test or Fisher’s exact test; the α level for significance was set at P < 0.05.

**Results**

We identified 313 RCTs for which the funding source could be ascertained; 83 (26.5%) were fully industry-funded, 78 (24.9%) had mixed funding, and 152 (48.6%) received no industry funding. RCTs fully funded by industry randomized more patients (median 385 vs. 255 patients, P = 0.0006), used more hospital sites (63.3 ± 29.9 vs. 10.3 ± 14.8, P < 0.0001) and were more likely to originate from North America (51/83; 61.4% vs. 84/231; 36.4%, P < 0.0001). Studies investigating drugs and devices accounted for over 90% of industry-funded RCTs. Non-industry-funded trials were more likely to investigate weaning/ ventilation and feeds/nutrition. A higher proportion of industry-funded RCTs recruited sepsis patients (35/83, 42.2% vs. 28/230, 12.1%, P < 0.001) and were more likely to originate from North America (51/83; 61.4% vs. 84/231; 36.4%, P < 0.0001). Studies investigating drugs and devices accounted for over 90% of industry-funded RCTs. Non-industry-funded trials were more likely to investigate weaning/ ventilation and feeds/nutrition. A higher proportion of industry-funded RCTs recruited sepsis patients (35/83, 42.2% vs. 28/230, 12.1%, P < 0.001) and were more likely to originate from North America (51/83; 61.4% vs. 84/231; 36.4%, P < 0.0001), whereas non-industry-funded RCTs were more likely to randomize neonatal or pediatric patients (22.2% vs. 10.8%, P = 0.02). The number of published critical care RCTs has increased over time, from 34 from 1990 through 1994 to 116 from 2005 through 2009. The proportion of fully industry-funded trials has been constant over time. Reporting of Data and Safety Monitoring Board involvement also increased over time for both industry-funded and non-industry-funded RCTs. Studies investigating drug interventions increased over time for industry-funded RCTs, but has remained relatively constant for non-industry-funded trials.

**Conclusions**

The total number of critical care RCTs has increased over time; a minority of these is fully funded by industry. Industry-funded trials are larger, more frequently originate from North America, and more frequently target patients with sepsis.

**P537**

Female authors in top-rank journals of different medical specialties

**Introduction**

In various scientific fields, including medical research, men have been found to have a higher scientific output than women. These differences may be due to women’s lower integration in the scientific community [1]. Even though the proportion of female authors has increased in the past decades, women still contribute less to prominent medical journals [2].

**Methods**

Thirty-five top-10-ranked journals of eight different medical categories were analysed: Medicine, General & Internal (M,GI), Critical Care (CC), Anaesthesiology (A), Surgery (S), Emergency Medicine (EM), Radiology (R), Haematology (H) and Clinical Neurology (N). Over a 12-month period, we evaluated the first and senior authors’ first name for gender.

**Results**

Thirty-one percent of evaluable first authors were female, compared with 18% of all senior authors. There were significant differences between the evaluated categories, with the lowest percentage of female first authors in the category Surgery, followed by Emergency Medicine (Table 1). In every category, the proportion of female senior authors was significantly lower than that of first authors.

**Conclusions**

There is a wide variation in the proportion of contributing female authors between the subspecialties analysed, probably reflecting the varying percentage of female scientists. However, in all evaluated medical categories, the proportion of papers authored by females was significantly lower than those authored by men.

National survey of protective eye care practices in the critically ill

**Introduction**

Critically ill patients with inadequate lid closure are susceptible to developing exposure keratopathy. Protective measures can prevent this and reduce the risk of subsequent microbial keratitis and irreversible visual loss. Of two published surveys [1,2], one was carried out before there was any evidence-based research in this area and the other did not address which methods were in use in ICUs. This study aims to describe the current eye care methods used in ICUs in England, the perceived incidence of eye complications, their nature and the effectiveness of protocols in use.

**Methods**

A team of researchers telephoned all general ICUs and other specialty critical care units in England caring for sedated, ventilated patients and asked a supervising nurse questions from a questionnaire piloted earlier in London.

**Results**

Two hundred and seventeen out of 267 ICUs (81%) participated. One hundred and thirty out of 217 (60%) ICUs had an eye care protocol. Sixty-six per cent of units with protocols assessed lid closure compared with 65% of those without. Gelperm application was the most common protective therapy (106 units, 49%), followed by Lacrilube (76 units, 35%). Most ICUs used a combination of methods. The total estimated incidence of ocular complications in the last year was 502. The most recent complications witnessed included corneal ulceration (23 cases), microbial keratitis (11) and chemosis (23). Cases of severe visual loss were caused by anterior ischaemic optic neuropathy following prone positioning (two cases) and microbial keratitis in a patient’s only functioning eye.

**Conclusions**

There is a need for protocols that encourage proper eyelid position assessment, effective protection of the ocular surface and referral to ophthalmologists in the event of any complications or any loss of corneal clarity.
Sleep disturbances in the ICU

Introduction
Sleep disturbances are common in critically ill patients on the ICU, with possibly serious consequences [1]. More attention is needed for the sleep–wake cycle of ICU patients. The aim of this study was to gain insight into factors that are important for sleep of critically ill patients on the ICU.

Methods
We conducted a multicentre, exploratory survey sent to nurse managers of all adult ICUs in the Netherlands. We used a self-developed questionnaire to describe which factors are important for sleep of ICU patients. Surveys were distributed via mail with subsequent written reminders. Relevant factors in relation with sleep of ICU patients were included in the questionnaire.

Results
The survey response rate was 60% (68/114). Characteristics of the sleeping patient on the ICU most often included: lying quiet with closed eyes (89.7%), decreased pulse rate (88.2%) and slower respiration (83.8%). Nonpharmacological interventions to improve sleep of the ICU patients most often comprised: keeping patients awake during the day (94.2%), lights out in the ICU (92.6%), use of a clock (91.2%), reducing noise of the ICU staff (89.7%) and reducing nursing interventions (86.8%). The type of sleep medication was mostly determined by physicians (57.4%). The assessment of the effects of the sleep medication was mostly determined by nurses and physicians together (58.8%). Most frequent medications used were midazolam (92.6%), propofol (85.3%) and temazepam (75.1%). Nursing observations influencing sleeping practices in the ICU (rated on a 10-point numerical scale) was judged as poor (median 5, IQR 3 to 7).

Conclusions
The average ICU patients are sleeping moderately well, mostly due to a disturbed sleep–wake cycle, delirium and nursing interventions. ICU nurses experience only a moderate feeling of autonomy and influence on sleeping practices. Most ICUs did not have a sleeping protocol, but more than one-half of these ICUs preferred to implement one.

Inhaled colistin for the treatment of ventilator-associated tracheobronchitis in critically ill patients

Introduction
Limited evidence exists regarding the efficacy of inhaled antibiotics in ventilator-associated tracheobronchitis (VAT) [1,2]. The aim of this study was to assess the effect of monotherapy with nebulized colistin on clinical and microbiological outcomes in critically ill patients with VAT due to polymyxin-only susceptible Gram-negative bacteria.

Methods
Patients were eligible for the study if they had clinical symptoms suggestive of VAT (for example, fever, purulent secretions), an absence of an evolving infiltrate on chest X-ray, and microbiological confirmation of VAT with quantitative cultures of endotracheal aspirates (ETAs) with a diagnostic threshold for VAT ≥10³ colony-forming units (CFU)/ml. Susceptibility to colistin was determined using the Vitek technique (Biomerieux, France). Selected patients received inhaled colistin at a dose of 1 million units every 8 hours for 7 days via a vibrating-mesh nebulizer (Aeroneb Pro; Aerogen, Galway, Ireland). Assessed clinical outcomes were cure, defined as resolution of signs and symptoms at day 5, and development of ventilator-associated pneumonia (VAP) at day 10 after initiation of treatment. Microbiological outcomes were defined as eradication and decline termed as isolation of ≤10² CFU/ml and were assessed by ETA quantitative cultures received at days 3 and 5 after initiation of treatment.

Results
Our study included 12 patients (eight men and four women) with mean age 58.7 years. The mean values of APACHE II and SOFA scores were 15.5 and 6.8, respectively. Two patients had polymicrobial Gram-negative VAT. Isolated pathogens from ETAs were: Pseudomonas aeruginosa (8/12 patients), Acinetobacter baumannii (5/12 patients), and Klebsiella pneumoniae (1/12 patients). Cure was achieved in nine out of 12 patients. In the three patients with clinical failure, intravenous colistin was administered. Two of them were subsequently cured and one patient developed VAP. Microbiological eradication was achieved in five out of 12 patients while decline was achieved in three out of 12 patients.

Conclusions
According to our limited data, monotherapy with nebulized colistin might be effective in the treatment of patients with VAT. Further investigation is warranted to evaluate whether nebulized antibiotics could effectively treat VAT and reduce the need for systemic antibiotics.
