We assisted the New York City Department of Education (NYCDOE) in designing a mechanism to match over 90,000 entering students to public high schools each year. This paper makes a very preliminary report on the design process and the first year of operation, in academic year 2003–2004, for students entering high school in fall 2004. In the first year, only about 3,000 students had to be assigned to a school for which they had not indicated a preference, which is only 10 percent of the number of such assignments the previous year.

New York City has the largest public school system in the country, with over a million students. In 1969 the system was decentralized into over 30 community school districts. In the 1990s, the city began to take more centralized control (Mark Schneider et al., 2000), and in 2002, a newly reorganized NYCDOE began to reform many aspects of the school system.

In May 2003, Jeremy Lack, then the NYCDOE Director of Strategic Planning, contacted one of us for advice on designing a new high-school matching process. The NYCDOE was aware of the matching process for American physicians, the National Resident Matching Program (Roth, 1984; Roth and E. Peranson, 1999). They wanted to know if it could be appropriately adapted to the city’s schools. The three authors of the present paper (and, at several crucial junctures, also Tayfun Sönmez) advised (and often convinced) Lack, his colleagues (particularly Elizabeth Sciabarra and Neil Dorosin), and the DOE’s software vendor, about the design of the match.

There are seven specialized high schools in New York City whose places are allocated by entrance exam (one by auditions). Rising high-school students (mostly 8th-graders, but some 9th-graders) could also apply to up to five other programs, by ranking them on a preference list. (Different high-school programs, with separate applications and admissions, are referred to here, interchangeably, as schools or programs. There are over 500 programs.) Just over 50 percent of students in 2002 applied to the maximum allowable five programs. Schools receiving a student’s application saw her list of preferences (and could see where they ranked on the list). How they processed applications varied by program type.

Unscreened programs admit students by lottery. Zoned schools give priority to students from the local neighborhoods, and many positions were filled this way. (One impetus for increasing school choice was to make sure students who lived in disadvantaged neighborhoods were not automatically assigned to disadvantaged schools.)

Screened programs can evaluate students individually. Educational Option (EdOpt) programs also can evaluate students individually for half their seats, subject to the restriction that 16 percent be allocated to students who were rated top performers in a standardized English Language Arts exam, 68 percent to middle performers, and 16 percent to lower performers. The other half of the seats are allocated by lottery, according to the same distribution of test scores. EdOpt programs were also subject to a special rule: any student with an ELA score in the top 2 percent would be automatically admitted if the program was ranked first on the student’s list. (Screened and EdOpt schools
Subject to these constraints, schools could decide which of their applicants to accept, place on a waiting list, or reject. Each applicant received a letter with the decisions of the schools to which she had applied, and applicants were required to accept no more than one offer, and one wait-list. This process was repeated: after the responses to the first letter were received, schools with vacant positions could make new offers, and after replies were received, a third letter with new offers was sent. New offers did not necessarily go to wait-listed students in a fixed order. Students not assigned after the third step were assigned to their zoned schools, or assigned via an administrative process. There was an appeals process, and an “over the counter” process for assigning students who had changed addresses or were otherwise unassigned before school began.

Three rounds of processing applications to no more than five out of more than 500 programs by almost 100,000 students was insufficient to allocate all the students. That is, this process suffered from congestion (Roth and Xiaolin Xing, 1997): not enough offers and acceptances could be made to clear the market. Only about 50,000 students received offers initially, about 17,000 of whom received multiple offers. When the process concluded, approximately 30,000 students had been assigned to a school that was nowhere on their choice list.

Three features of this process particularly motivated NYCDOE’s desire for a new matching system. First were the approximately 30,000 students not assigned to a school they had chosen. Second, students and their families had to be strategic in their choices. Students who had a substantial chance of being rejected by their true first-choice school had to think about the risk of listing it first, since, if one of their lower-choice schools took students’ rankings into account, they might have done better to list it first. (The 2002–2003 Directory of the New York City Public High Schools advises students (p. x) that, when ranking schools, they should “... determine what your competition is for a seat in this program.”) A similar problem occurs in Boston schools (see Abdulkadiroglu and Sonmez, 2003; Abdulkadiroglu et al., 2005). Third, schools were also strategic: a substantial number of schools apparently managed to conceal capacity from the central administration, thus preserving places that could be filled later.

II. Design of the New System

Initial discussions focused on whether the medical match was a good model for New York City schools, or whether another kind of clearinghouse might be more appropriate. The medical match applied to schools would be a two-sided model in which both schools and students have preferences, with the object of implementing a stable assignment, that is, an efficient assignment such that no school and student not matched to one another would both prefer to be. Thus, the question was, are the students the only real players in the system, with choices by schools merely a device for allocating scarce spaces? If this were the case, there might be appropriate one-sided clearinghouse models in which only student preferences determine efficient allocations (cf. Boston Public Schools; Abdulkadiroglu et al., 2005).

Two things convinced us that New York City schools are a two-sided market. The first was that schools withheld capacity to match with students they preferred. Stable assignments would eliminate the main incentives for this. Second, discussions indicated that principals of different EdOpt schools had different preferences even for students with reading scores in the lowest category, with some schools preferring higher scores and others preferring students who had good attendance. If schools have different comparative advantages, allowing scope for their preferences seemed sensible. Also, the fact that school administrators gamed the system indicated they were strategic players.

The medical match employs an applicant-proposing deferred-acceptance algorithm (David Gale and Lloyd Shapley, 1962; Roth and Peranson, 1999). Ignoring for the moment the details of New York City schools, this could be applied as follows. Students and schools rank each other (schools do not see students’ preferences), and the clearinghouse processes these lists so:

(i) Each student applies to her highest ranked school, and each school rejects unranked applicants and “holds” its highest ranked...
applications (up to the number of positions
it has) and rejects the rest.

(ii) At any stage at which a student has been
rejected, she applies to her next most pre-
ferred school if one remains. Each school
holds its most preferred set of applications
and rejects the rest.

(iii) The algorithm stops when no rejections are
issued, and each school is matched to the
applicants it is holding.

No student would receive multiple offers. We
discussed whether this was an unmixed benefit:
students who received multiple offers in the old
system might benefit from this (e.g., in in-
creased decision time). But relatively few such
students chose a school different from their
indicated preferred choice, so this seemed like a
bearable cost, considering that in a system with-
out excess capacity the cost of giving some
students multiple offers is that multiple students
get no offers.

The next design choice was whether the al-
gorithm should be student-proposing, or another
stable mechanism (e.g., schools-proposing). A
student-proposing algorithm was selected be-
cause this has the best welfare properties for
students and (in sufficiently simple environ-
ments) makes it a dominant strategy for students
to state true preferences (and since no alter-
native stable mechanism gives schools straightfor-
ward incentives [Roth and M. Sotomayor, 1990;
Sönmez, 1997]).

Of course, adapting the mechanism to the
regulations and customs of New York City
schools involved departures from the simple
algorithm (cf. Roth, 2002). Schools that allo-
cated seats by lottery are assigned randomly
generated preferences. Each (half) EdOpt pro-
gram is treated as three different programs
whose preferences must reflect the 16/68/16
reading score distribution. If a student ranked an
EdOpt school, this was treated in the algorithm
as a preference for one of the random slots first,
followed by a preference for one of the slots
determined by the school’s preferences.

The EdOpt automatic admit for top-2-percent
students who choose it first could not be
changed, although this adds strategic risk to the
decisions of students who are eligible to use it.
Another decision that makes some students not
have a dominant strategy is that preference lists
were limited to a maximum of 12 schools. Over
22,000 students listed 12 in the first year, so this
was a binding constraint. These choices are
therefore candidates to be revisited when mod-
ifications are considered.

NYCDOE wanted students who are offered
specialized-school positions also to be given an
offer from a nonspecialized school. Therefore
students who applied to specialized schools
submit a preference list of nonspecialized
schools along with all other students, and a first
round of the algorithm is run with all students.
Students who receive a specialized-school offer
receive a letter giving them a choice between that
exam school and a nonspecialized school. After
they respond, capacities are adjusted, students
who accepted offers are removed, and the algo-
rithm is run again. Only after this second round
are students who did not receive specialized-
school offers told their assignment.

We would have preferred to integrate these
two rounds into one, by having applicants in-
clude the specialized schools in their preference
lists. (The two-round design creates a possibil-
ity of unstable allocations, as when a student
gets an offer from a specialized school, but not
from a nonspecialized school he prefers that
would have had a place for him after the
specialized-school students have declined places.)
However, if students who are offered specialized-
school places generally rank high in all schools’
preferences, this may not be a big problem.

Students who were unassigned after the sec-
ond round were informed of the schools with
empty places and asked for another preference
list of up to 12 schools. The NYCDOE felt there
would be insufficient time to elicit new prefer-
ences from schools (a decision that might use-
fully be reviewed in the future), and so these
students were ordered in a single random list
that was used as the preferences for all schools
in a third round of the algorithm. (This com-
pares favorably with alternative methods of
randomization.) The small number of stu-
dents who remained unmatched were assigned
administratively.

III. First Year of Operation

The new match matched over 70,000 students
to a school on their initial choice list, an in-
crease of more than 20,000 students compared
to how many received one of their choices the previous year. An additional 7,600 students who were unmatched based on their initial preferences were assigned to schools based on the preferences they submitted over schools that still had vacancies.

Of over 90,000 students who submitted preferences, approximately 8,000 students withdrew from the New York City public schools, and more than 2,000 remained in their current school either in a 9th-grade program or through failure to graduate, leaving approximately 3,000 students who did not receive any school they chose. This compares to the approximately 30,000 who NYCDOE reports were administratively assigned, mostly to zoned schools, the previous year.

Much of this difference is due to allowing students to rank 12 instead of five choices, and to giving each student a single offer, rather than multiple offers to some students. Interestingly, it appears that at least 3,000 more students received one of their first five stated choices than in the previous year, under the old system.

Just over 5,100 students appealed their assignments, around 2,600 were granted on a case-by-case basis. (Around 300 appeals were from students who received their first choice. Some of these may have had to do with bad information about new programs. But some may reflect the difficulty of soliciting preferences involving 13–14-year-olds.) Designing an efficient appeals process remains a priority.

Thus despite some significant first-year problems of communication and implementation, the new match seems to have achieved many of its goals.

IV. Conclusions

New York City needs more good schools. But for a given stock of school places, more students can be admitted to schools they want if the matching process is free of congestion, so that students’ preferences can be fully taken into account. The new clearinghouse, organized around a stable matching mechanism, has helped relieve the congestion of the previous offer/acceptance/wait-list process and provides more straightforward incentives to applicants.
